

# FRONTISPIECE.

Engraved on Steel by R. Page, from a Drawing by J. Fussell.

A

## DICTIONARY

OF

## MECHANICAL SCIENCE,

## Arts, Manufactures,

AND

## MISCELLANEOUS KNOWLEDGE.

COMPRISING

THE PURE SCIENCES OF MATHEMATICS, GEOMETRY, ARITHMETIC, ALGEBRA, &c.;—THE MIXED SCIENCES OF MECHANICS, HYDROSTATICS, PNEUMATICS, OPTICS, AND ASTRONOMY;—EXPERIMENTAL PHILOSOPHY;—THE FINE ARTS;—AGRICULTURE, AND ITS IMPLEMENTS;—MANUFACTURES, AND THEIR VARIOUS PROCESSES;—COMMERCE AND DOMESTIC ECONOMY;—NATURAL HISTORY;—WITH BIOGRAPHICAL AND HISTORICAL NOTICES OF EMINENT MEN, WHO HAVE ADORNED SCIENCE BY THEIR INVENTIONS AND DISCOVERIES.

---

Illustrated with many Hundred Engravings.

---

Studies serve for delight, for ornament, and for ability: they perfect nature, and are perfected by experience. Crafty men contemn studies, simple men admire them, and wise men use them. Read not to contradict and confute, nor to believe and take for granted; nor to find talk and discourse, but to weigh and consider. Some books are to be read only in parts; others to be read, but not curiously; and some few to be read wholly, and with diligence and attention.

LORD BACON.

---

BY ALEXANDER JAMIESON, LL.D.

---

VOL. I.

LONDON:

PRINTED FOR HENRY FISHER, SON, AND CO. NEWGATE-STREET.

1833.

TO THE RIGHT HONOURABLE

FREDERICK JOHN ROBINSON, VISCOUNT GODERICH.

---

My LORD,

THE various wants of society are supplied by the daily operations of human industry; but with the increase of society those wants accumulate, and ingenuity is then compelled to exert itself, to abridge manual labour, and render it more productive. Yet how many germs of invention blossomed before London was illumined by gas, or the vast Atlantic was navigated by a steam vessel? Three hundred years ago, the diligence of the press began to multiply the erudition of the ancients: this mighty engine has rolled on the tide of discovery in a rapid and majestic stream; the age of science has succeeded the age of literature; and a rational philosophy has invested our species with a full blaze of intellectual glory. Mankind now universally acknowledge, that we are indebted for many of the comforts, enjoyments, and delicacies of civilized life, to the prodigious improvement and extension of scientific pursuits, since the genius of observation and experiment dawned upon European society. Among the sciences which have contributed to furnish these comforts, there is none that ranks higher than Mechanics, for it is indisputable that several popular sciences are but handmaids to this; and if we look around us at all the stupendous undertakings going on in the world, we shall find them moved by machinery, or constructed by means of artificers, whose operations proceed entirely upon mechanical principles.

A Dictionary of Mechanical Science necessarily includes definitions and illustrations of numerous peculiar words and terms of expression found only in the works of those authors who have written on the Mathematical Sciences. To furnish precise ideas, and yet brief explanations, of all such words and terms, is the province of a Dictionary. But the present work embraces also the Arts, Manufactures, and various subjects of domestic economy adapted to the purposes of common life, and of course includes definitions and illustrations of numerous terms and principles scattered over the circle of Arts and Sciences, together with such other information as was deemed instructive, and subservient to a work of such universal reference.

Hence it will also be found, that all theoretical subjects are handled with brevity, while those which are practical, and applicable to the purposes of ordinary life, have been dwelt upon at length, and their relations and dependencies fully described and illustrated by appropriate Engravings; thus affording ocular as well as intellectual proof of the topics introduced to the reader's notice. And with the explanatory matter are introduced such historical facts and biographical notices as were conducive to the nature and design of the work. But while new principles and new subjects of investigation can hardly be expected in a volume, the professed object of which is to detail the discoveries and improvements of preceding writers; the most recent and original views in Science and Art, the result of modern experiments, and inventions and discoveries that are but of yesterday, obtain a place in this work; yet no novelty has been admitted here at the expense of simplicity, perspicuity, and truth.

In describing the Construction of Machines, and explaining their various uses, conciseness of expression will be no less evident than the introduction of familiar words, where their appearance tells all that was said by the pompous derivatives which too often obscure scientific writings. The principle of selection expressed in the title of the work, has afforded me ample space for many new articles of useful information in the Arts, which have hitherto been overlooked, or confined to voluminous and expensive publications. In a word, condensation of matter, and abridged descriptions, accompanied by intelligible Drawings, are the principles on which this work is constructed. Obsolete theories have been entirely omitted, and conflicting opinions disregarded, in order to present the reader with a Dictionary of subjects and ideas, rather than of words, and shreds of obscure biography.

It was impossible, however, to avoid all theory, especially in some parts of the mixed sciences; yet I am not conscious of having adopted the opinions of empyrics, or the doctrines of system makers. I have tried to follow *truth in method*, and to present my readers with a well-digested compendium of human knowledge, alphabetically arranged, and exhibiting science in a form that is indispensable to those who have little leisure for abstruse study, or have served no apprenticeship in thinking methodically. The education of the understanding, by awakening the method of self-development, was the object of the great Plato; it has been mine, without the vanity of comparison, while I introduced my readers to such relations and circumstances as might gradually inspire new sources of intellectual delight, to replenish their minds with the various sorts of knowledge most congenial to their pursuits in the different departments of Mechanical Science.

I have endeavoured, my Lord, to make my work useful rather than shining, and, from beginning to end, I have thence remembered that I was collecting information for the great body of the British Nation, who, by the "daily operations of human industry," are employed in providing for the wants of an artificial state of society. But there is a point at which the labours of every individual must stop, and he can then only look with surprise at the numerous temptations which excessive wealth holds out to needy genius in creating fresh wants, and thus reciprocally alluring pampered luxury to riot in new and untried enjoyments. Such, indeed, is civilized society in Great Britain; and there is no man who knows better the multiplicity and variety of its operations and wants than your Lordship, nor one who has more laboriously striven to alleviate the hard condition of the poor, and augment the comforts of the rich. It is, therefore, a source of much pleasure to me that my labours are honoured with the Permission of being dedicated to a Nobleman who has so deservedly won the applause of the first nation upon earth.

I have the honour to be,

My LORD,

Your Lordship's obedient and humble Servant,

WYKE HOUSE,  
SION HILL, MIDDLESEX,  
Sept. 5th.

ALEXANDER JAMIESON.

## INTRODUCTION.

---

SCIENCE first shed her genial beams in the cheerful climes of the East; there, to use a homely phrase, her cradle was first rocked, and the curiosity of men was first awakened by the changes incessantly passing around them; but experience soon proved the constancy and regularity of this varied spectacle; and the vast movements of this stupendous and magnificent universe were all found to consist merely in a repetition of similar and uniform events.

The unfettered genius investigated physical facts by observation and experiment; observation examined the phenomena which arose in the course of nature; experiment, more artificial in its selection and combination of circumstances, searched minutely after the different results of those phenomena.

But there arose, through the ignorance and fears of mankind, a priesthood that inculcated the adoration of numberless divinities, and, proscribing the range of observation, broke in pieces the implements with which experiment had been exploring the secrets of nature. Hence the wise men of antiquity concealed their notions of science under the veil of allegory. This was the natural result of knowledge passing from the lips of unshackled genius to those of a gloomy priesthood, who employed it merely as an engine of power, and thus consigned the discoveries of happier times to the silence of despotism, and the cheerless tomb of superstition.

The two great streams of knowledge were thus soon separated widely apart,—and they continued to flow through very opposite channels. That which had pure intellection for its object, and which confined itself to morals and ethics, soon became foul and disagreeable, as, enveloped in the fog of superstition, it traversed the filthy soil of despotism;—the

other, which moved through the region of physical science, preserved its purity and salubrity. Hence, while the miserable sophisms and arcana of intellectual philosophy, among the ancients, have remained the same for 3000 years; their geometry, and some branches of physical science, have, in modern times, been carried to a sublime elevation.

From the East, science travelled slowly into the early civilized nations and states of Europe. Greece first gleaned instruction in the seats of Asiatic renown, and, as the tutor of European society, she will be immortalized as having conferred eternal benefits on the human race.

THALES, after many years spent in foreign travel, transplanted into Greece the science of the Egyptian priests; and his successors, ANAXIMANDER and ANAXIMENES, pretended to explain the origin and formation of all things, and taught, that every substance whatever was composed of four distinct elements—earth, water, air, and fire.

It was a mere speculation, flattering to human vanity, that contemplated the stars consisting of fire, and the vital spark as a portion of its divine essence. Though we smile at these fantastic notions, they were as firmly believed in former ages by the learned as by the common people.

ANAXAGORAS, under the priests of Egypt and the Magi of Persia, acquired both elegance and learning.

PYTHAGORAS, endowed by nature's choicest gifts, after thirty years' study in the East, settled in Italy, and strenuously urged the study of mathematics, especially those concerned about number and proportion. This love of numerical relations led him to cultivate music both as an art and a science, and he even transferred his ideas of this science to the harmony of the celestial motions. This was no

error of Pythagoras; he could only teach the people in the temples and other public places, and to them he imparted the true system of the universe, under that noble allegory of Apollo playing on his lyre. To his chosen disciples those recondite principles of astronomical science were taught with mathematical precision; but both master and pupils affected to believe, that those bodies, while they revolved round the sun as the common centre of the universe, performed a most harmonious concert, though such ravishing and heavenly sounds were lost to the gross ears of mortals, and drowned amidst the jarring elements on earth.

EMPEDOCLES, the Sicilian, and successor of Pythagoras, conceived the doctrine of atomic attraction and repulsion. XENOPHANES distinguished himself as the prince of geologists, by teaching that the fossil shells and marine exuviae, discovered in the bowels of the earth, and on the tops of the highest mountains, had, at some remote period, been formed under the waters of the ocean. LEUCIPPUS, of the same school, added the doctrine of a separate plenum, and anticipated the influence of centrifugal force. DEMOCRITUS, after visiting the East, and consulting the Magi of Hindostan, rectified many of the prevailing errors in physics. He shewed, that the existence of a plenum was incompatible with local motion; he rejected the levity attributed to the air and fire, and maintained that the weight of bodies is always proportioned to their mass or quantity of matter, and that they would hence fall in vacuo with equal swiftness. Of light and heat he entertained correct general views; and all his tenets are expounded by LUCRETIUS.

SOCRATES, next in order, diffused among the Athenian youth a more solid system of education, by commending only that philosophy which is grounded on fact and experiment. The unmeasured contempt which the sage poured on hypocrisy and pretension, roused the jealousy and rage of his enemies; and the venerable man fell a martyr to the cause of truth, his love of virtue, and his devotion to wisdom.

PLATO, shocked at the murder of his revered master, withdrew from the polluted city; and after visiting the Pythagoreans at Tarentum, and learning the whole system of the Italic school, next placed himself under the tuition of THEODORUS, the eminent mathematician of Cyrene, in Libya. On his return to Greece, he purchased the grove of Academus, in the neighbourhood of Athens, and the youth of Greece flocked from all parts to study the beautiful method of geometrical analysis, which extended the boundaries of science, and led to the discovery of

conic sections,—a doctrine which, in more recent times, taught GALILEO the laws of motion, and KEPLER the true orbits of the planets.

Stagira, a small town on the confines of Thrace and Macedon, gave birth to ARISTOTLE 380 years before the age of Augustus. The authority of the Stagiran long maintained a despotic sway in the schools. Aristotle was tutor to Alexander the Great, and no philosopher has taken a wider range of disquisition, none ever discovered a greater soundness of judgment, or more precision of thought. He was the founder of comparative anatomy, and the divisions he introduced are still the best that could be made. His meteorology sparkles with fine remarks and just conclusions. His physics contain interesting doctrines, mixed up with idle and extravagant speculations. But the mind of Aristotle was drawn aside by the love of subtlety, and the illusion of general hypothesis, from the strict investigation of facts.

In the museum of Alexandria in Egypt, PTOLEMY, to whose lot this country fell on the premature death of Alexander, established men of science, and provided them with books and instruments for the prosecution of their studies. The munificence of his successors aggrandized the institution by a vast library and royal observatory, which for 900 years conferred incalculable benefits on mankind. There, EUCLID digested the elements of geometry, which remain to our times: there, APOLLONIUS, PAPPUS, DIOCLE, and NICOMEDES, extended the conic sections, and improved geometrical analysis; and there, too, DIOPHANTUS flourished.

Navigation extended the knowledge of mankind respecting the surface of the globe; and the Grecian colony at Marseilles had the merit of fitting out the first voyage of discovery, though Phœnicians were, without doubt, the earliest navigators that passed the pillars of Hercules. EUTHYMENES crossed the equator, PYTHIAS discovered the remote Thulé; he noticed the phenomena of the tides, and determined the obliquity of the ecliptic at  $23^{\circ} 48'$ . But our reverence for the knowledge of Pythias is modified by the fact, that 700 years before the age of Julius Cæsar, the Babylonians recorded eclipses of the moon, an event in science that is marked by HIPPARCHUS and PTOLEMY. And the Indians, from whom Pythagoras derived his knowledge, have two principal epochs, one about 3000, and the other 1500 years before the Christian æra. Hipparchus flourished 140 years before our æra; and was contemporary with Ptolemy the geographer.

In the circle of mechanical science we are compelled, by the nature of our Introduction, to range,

and must, therefore, notice next in order of time and genius, the illustrious ARCHIMEDES, of Syracuse in Sicily, who gave unlimited extent to the rotation of numbers, and founded the method of indivisibles, which led to the finest discoveries in geometry. In mechanics and hydrostatics he had no rival: he pointed out the centre of gravity, and determined its position in a number of figures; he unfolded the properties of floating bodies, and thus became the father of naval architecture. The vast engines which he constructed for the defence of the city of Syracuse, enabled his countrymen for three years to resist the overwhelming force of the Romans.

Of the Alexandrian school many philosophers applied themselves to mechanics, as CTESEBIUS, who improved the clepsydra, invented the pump, and constructed an engine for discharging arrows by means of condensed air; and Hiero not only constructed the crane, but invented machines which acted from the variable elasticity of included air, as affected by heat and cold; a principle which afterwards led Galileo and Sanctorio to the construction of thermometers, and the Marquis of Worcester to the contrivance of the steam-engine.

We look with measured contempt upon the Romans as regards science, whether in a theoretical or a practical point of view. Their studies and learning were altogether to form statesmen or orators. They invented nothing; the lever, the pulley, the crane, the capstan, and other simple machines, were employed by the ancient architects a thousand years before Rome had existence. The catapultæ and ballistæ, those compound mechanical engines of the Romans, exhibit amazing knowledge of machinery; but these or similar engines were common to the Greeks also; and we know that for ages the people of Italy ground their corn in hand-mills, with a fixed and moveable millstone. The art of naval architecture they learned from the Carthaginians; and in the destruction and annihilation of their once flourishing empire, they have amply shewn how completely destitute they were of those great and noble qualifications which distinguished their tutors the Greeks.

The Arabians, who studied geometry and astronomy, botany and chemistry, stored the palaces and libraries of their caliphs with the science of the Greeks, which they translated into their own language. About the tenth century of our æra, the use of the ten digits in arithmetic was introduced by the Arabians into Spain. As chemists, the followers of the Prophet brewed and distilled, and even the very names of our chemical vessels are Arabic; but of brewing and distillation, we know not that either the Greeks or the Romans knew any thing.

From the beginning of Constantinople, which rose like the work of a fairy genius, till the period when the Arabians spread the elements of science over Europe, the wrecks of knowledge lay buried in the convents; mental darkness brooded over the fairest lands of Christendom, and the more active spirits wasted their energies in brutal sports and savage depredations.

The Crusades opened the gates of refinement, and from the twelfth to the fourteenth century the chains of feudal tyranny were gradually broken; the middle class of men, that great bulwark of every free state, insensibly rose; and with the renovation of the human intellect, even in the benighted period of the middle ages, paper was manufactured from linen rags—the eyes of the aged were assisted by the invention of spectacles about the year 1285—and the construction of the mariner's compass having been made about the close of the thirteenth century, at Amalphia near Genoa, gave a prodigious impulse to navigation and commercial speculation. SWARTZ, a German monk, in 1382, extended the empire of man over nature, by the invention of gunpowder. About the beginning of the fifteenth century, the ingenuity and perseverance of Guttenberg and Schoeffer, encouraged by the wealth of Faust, a rich burghess of Mentz, conferred upon mankind the art of PRINTING, the greatest benefit ever bequeathed on the human species, except that of speech or writing. In thirty years after its first discovery, the art of Printing was carried to a pitch which has never been surpassed.

SCHOEFFER, the oldest engraver also on wood, executed in 1491 a series of figures of plants and animals on wooden blocks. The clergy were now anxious to promote learning, as the only means of enriching themselves, and schools were accordingly opened in the convents and monasteries for the education of youth. In process of time, papal bulls elevated these schools to universities; and an apprenticeship of seven years, copied afterwards in the mechanical trades, completed the course of education, and made the students masters of Aristotle's tenets.

COPERNICUS restored the true system of the world; PURBACH and MÜLLER abridged astronomical calculations; UBALDI and STEVINUS extended the principles of mechanics and hydrostatics; GALILEO discovered the laws of motion; KEPLER and TYCHO BRAHE were men of the first order of genius as astronomers. And NAPIER immortalized his name by the sublime discovery of logarithms.

The alchymists, though extravagant in their pretensions, promoted experimental science, and the various societies that were established over Italy

under this name, set an example that was followed all over Europe. Dr. GILBERT, in England, treated of magnetism; SNELLIUS discovered the laws of incidence and refraction, which DES CARTES simplified in the explication of other properties of light, and the brilliant phenomena of the rainbow. The application of algebra to geometry by the same skilful hand effected a memorable revolution in mathematical science.

TORRICELLI'S invention of the barometer, GUERICKE'S construction of the air-pump, the numerous mechanical inventions of DR. HOOKE, and HUYGENS, have enriched the stores of human knowledge, and added many valuable and profitable desiderata to the circle of domestic comforts and scientific pursuits.

The penetration of NEWTON, that ranged through the immensity of celestial space, could define the figure of the earth, and calculate the tides of the ocean; and he commanded geometry to preside over the properties of water, the motion of currents, the propagation of sound; and the sagacity of that genius, which has never been excelled, disclosed still greater wonders in its fine researches in optics, when it

“Untwisted all the shining robe of day.”

MACLAURIN died in his prime, but COTES, BRADLEY, and the MARQUIS of WORCESTER, have left behind them names that are imperishable.

Without ransacking the biography of the continent for such names as BERNOULLI, EULER, D'ALEMBERT, CLAIRAUT, LAGRANGE, PRONY, COULOMB, LAPLACE, PIAZZI, OLBERS, HARDING, MALUS, GALVANI, ORESTED, BERZELIUS, we may confine our notice to Britain, where CAVENDISH, ATWOOD, EMERSON, SMEATON, DAVY, SIR WM. HERSCHEL, JAS. WATT, PLAYFAIR, and LESLIE, of Edinburgh, and DR. OLINTHUS GREGORY, of Woolwich, have contributed largely to the advancement of mechanical philosophy, and the application of mechanical power.

On the progress of mechanical science in the abridgment of human labour, by the diversified appli-

cation of steam and machinery in our manufactures and arts, it may be naturally expected that something should be said.

There can be no doubt, that these mighty auxiliaries have enabled Great Britain to compete with foreign nations in all the markets of the world; but whether the power, wealth, and stability of our country have been essentially promoted by the acquisition, may appear somewhat problematical. Unhappily, the diminution of manual labour, which enriches the merchant, tends to impoverish the working classes, and, by contracting the field in which industry might display its energies, to foster indolence and vice, which cannot but entail misery on future generations. Time, however, may find new sources of employment for productive labour, and posterity may look back on this *age of machinery*, as we look on the era when the invention of printing deprived thousands of scribes of their daily bread. But on this important and deeply interesting question, it is not the province of the author to decide.

In the compilation here presented to the reader, facts, not theories, demand his attention. The selections have been made from the most authentic sources of information to which the author could have access. These being arranged in alphabetical order, no difficulty can occur when any particular article is wanted for examination; and he flatters himself, that by the distribution of the plates, all confusion will be prevented, when references are required for the elucidation of any given subject.

In taking leave of his reader, he has not the vanity to think that his work can triumph in the omission of all error. From anomalies and defects no volume of this magnitude was, perhaps, ever wholly free. For these he has no apology to offer, and he only solicits from the considerate and candid reader, the same degree of liberality and forbearance, which, under similar circumstances, he would wish to enjoy.

A. J.

WYKE HOUSE, June 1827.

# A DICTIONARY

OF

MECHANICAL SCIENCE, THE ARTS, MANUFACTURES,

AND

DOMESTIC ECONOMY.

A B A

**ABACK**, a Sea term, indicates the situation of the sails of a vessel, when the surfaces are flattened against her masts by the wind. The sails may be taken aback, either by a sudden change of wind, or the alteration of the ship's course. They are laid aback to give the ship stern-way, in order to avoid some danger ahead. To *aback* sails, the men slacken the lee braces and haul the weather ones; the wind then blowing upon their front surface, drives the ship astern, unless she is restrained by some counteracting force, as when she rides at anchor, and then only the mizzen-top sail is *abacked*.

**ABACUS**, a small table covered with sand, on which the ancient mathematicians drew their diagrams, in the same way as children are taught to write in our Lancasterian and Bell schools.

**ABACUS**, in Architecture, the superior part or member of the capital of a column, serving as a crown to both. The Abacus originally represented a square tile laid over the mouth of an urn or basket. The form of the Abacus is the same in all the orders. See ARCHITECTURE.

**ABACUS**, the name also of an ancient instrument for facilitating the operations of arithmetic. This instrument is made by fixing a number of parallel chords or wires, at the distance

A B A

of two diameters of one of the counters used in the calculation as represented in the engraving. A counter placed on the lowest chord signifies 1; on the second, 10; on the third, 100; on the fourth, 1000, &c. In the intermediate parallels, the counters are valued at one half the value of the chord immediately above; thus, between the 1st and 2d chord, a secondary chord may be fixed, and on it the value of the counter for 5; between the 2d and 3d chords 50, and so on. In the diagram before us, where the numbers 1824 and 1823 are represented in two compartments, the first is regularly units, tens, hundreds, thousands, 1824; in the second we read 1000, 500, 300, 20, 3; which, added together, is 1823.

MECHANICAL ARITHMETIC:

Fig. 1. The Year of the Christian Era.

Fig. 2. Finances of Great Britain for 1823—1824.

|                         |                              |                          |                          |                                      |                |
|-------------------------|------------------------------|--------------------------|--------------------------|--------------------------------------|----------------|
|                         |                              |                          |                          |                                      | Tens Millions. |
|                         |                              |                          |                          |                                      | Millions.      |
|                         |                              |                          |                          |                                      | Hun.Thousands  |
|                         |                              |                          |                          |                                      | TensThousands  |
|                         |                              |                          |                          |                                      | Thousands.     |
|                         |                              |                          |                          |                                      | Hundreds.      |
|                         |                              |                          |                          |                                      | Tens.          |
|                         |                              |                          |                          |                                      | Units.         |
| Income.<br>£57,672,999. | Expenditure.<br>£50,962,014. | Imports.<br>£35,751,698. | Exports.<br>£52,498,277. | Colonial<br>Merchandise<br>Exported. |                |

Thus: - 50,000,000  
7,000,000  
600,000  
70,000  
2,000  
900  
90  
9

Here the upper line reads in the Income compartment, for instance, 50,000,000; the next line, 7,000,000; the third, 600,000; the fourth, 70,000; the fifth, 2,000; the sixth, 900; the seventh, 90; and the eighth, 9:

£ 57,672,999

And in the same manner all the other compartments of the Abacus are used.

**ABACUS**, a table of numbers ready cast up, and used by the moderns, to expedite the operations of arithmetic.

The *Grecian* **ABACUS** was an oblong frame, over which several wires or threads were stretched, strung with ivory balls, like the beads of a necklace; by the various distributions of which, all the operations of addition, subtraction, multiplication, and division, were mechanically performed.

The *Roman* **ABACUS** differed from the above, by having pins sliding in grooves, instead of strings or wires, and beads.

The *Chinese* **ABACUS** corresponds with the *Grecian*.

The **ABACUS** *Pythagoricus*, is the common multiplication table: the **ABACUS** *Logisticus*, or *canon* of sexagesimals, is a rectangled triangle, whose sides forming the right angle, contain the numbers from 1 to 60; and its area the result of each two of the numbers perpendicularly opposite. The **ABACUS** *Harmonicus* of Kircher, denotes the structure and disposition of the keys of a musical instrument. And the **ABACUS** *Major* in metallurgic operations, is the name of a trough used in the mines for washing ore.

**ABAFT**, a Sea term, the hinder part of a ship; towards the stern.

**ABAISSED**, in Heraldry, applied to the wings of eagles, &c. when the tips droop to the point of the shield; or when the wings are shut, the natural way of bearing them being *volant*, or extended.

**ABALIENATION**, in Law, the act of transferring one man's property to another.

**ABAPTISTON**, in Surgery, the perforating part of the *trep-*an instrument.

**ABARTICULATION**, in Anatomy, a species of articulation admitting of manifest motion; called also *Dearticulatis*, to distinguish it from that articulation which admits of very obscure motion, and is called *Synarthrosis*.

**ABAS**, a Persian weight for weighing pearls; one-eighth less than our carat.

**ABATAMENTUM**, in Law, an entry to lands by interposition: *i. e.* when a person dies, seized, and another who has no right, enters before the heir.

**ABATE**, in Horsemanship, the performing of any downward motion properly, as in curvets, when both the hind legs touch the ground at one and the same moment.

To **ABATE**, a Law term:—thus, *to abate* a castle, is to pull it down; *to abate* a writ, is to defeat or overthrow it. A stranger *abates*, *i. e.* enters upon possession, of house or land, void by the death of him that possessed it, before the heir takes possession, and so keeps him out. The writ of the defendant *shall abate*, *i. e.* be overthrown. The appeal *abateth* by covin, *i. e.* the accusation is defeated by deceit.

**ABATELMENT**, in Commerce, a prohibition of trade to all French merchants trading to the Levant, who will not stand to their bargains.

**ABATEMENT**, in Heraldry, signifies an accidental figure in coats of arms, expressive of a stain, or dishonour.

**ABATEMENT**, in the Customs, an allowance made upon the duties of goods that have been damaged.

**ABATIS**, in Fortification, an entrenchment made of felled trees, the trunks being planted in the ground, and the branches interwoven.

**ABATOR**, in Law, the person who enters a house or lands, on the death of the occupier, before the just heir.

**ABB**, among Clothiers, signifies the warp of a web, or the yarn used for warp. They also say *abb-wool*, in the same sense.

**ABBA**, the Syriac and Chaldean name for Father. In the Coptic and Ethiopic churches the bishops are *Abbas*.

**ABBE**, a Monastic term, an Abbot; latterly in France the *Abbés* were academics, tutors, &c. but not properly churchmen.

**ABBESS**, the superior of a convent of women. Formerly the Abbesses confessed their nuns; but female curiosity carried them such lengths in extracting secrets, that the sex were deprived of this jurisdiction over their sisters' conscience. St. Basil's rule allows the presence of an Abbess at the confessional of her nuns.

**ABBEY**, a Monastery, or religious house, governed by a superior, either male or female, according to its destination.

**ABBOT**, the superior of a monastery of monks, erected into an abbey or priory. There are various classes of Abbots, as

*mitred, crosiered, ecumenical, cardinal, regular, and commendatory* Abbots.

**ABBREVIATE** of *Adjudications*, in Scotch law, an abridgment, or abstract, of a decree of adjudication, which is recorded in a register kept for that purpose.

**ABBREVIATION**, or **ABBREVIATURE**, the contraction of a word by dropping some letters, or of a passage, by the omission of some words: as, A. U. C. *ab urbe conditâ*, from the Building of the City; *I. E. id est*, that is; E. G. *exemplâ gratiâ*, for example; A. M. before noon; P. M. afternoon.

**ABBREVIATION** of *Fractions*, reducing them to lower terms. See **FRACTIONS**.

**ABBREVIATOR**, the Person who shortens or abridges any work. The *Abbreviatores* of the chancery at Rome are 72 clerks, who abridge all petitions, &c. for the Pope's perusal, previously to the said documents being passed into *bulls*, or ecclesiastical mandates.

**ABBUTTALS**, the buttings or boundings of land towards any point, distinguished anciently by artificial hillocks.

**ABCEDARY** *Psalms*, &c. whose parts are arranged according to the order of the letters of the Hebrew alphabet: as, Psalm 25, 34, 119.

**ABDICATION**, the action whereby a magistrate, or person in office, renounces or gives up the same before the term of service is expired; and in this wise differs from *resignation*, which implies a giving up in favour of some other person. Dioclesian abdicated; the Emperor Charles V. resigned.

**ABDUCTOR**, in Anatomy, the muscle that withdraws, opens, or pulls back, the parts to which it is attached.

**ABELE**, the hoary or white poplar, which grows very fast, and sometimes to the height of 70, 80, and 100 feet. It flourishes well in a clayey soil, on the low banks of streams, or on the margin of ponds; and the wood, which is soft and white, is much used by turners. Horses, sheep, and goats, browse upon the leaves, but cows avoid them.

**ABERRATION**, in Astronomy, an apparent motion of the celestial bodies, produced by the progressive motion of light, and the earth's annual motion in her orbit.

**ABERRATION** of the *Planets*, is equal to the geocentric motion of a planet; the space it appears to move, as seen from the earth, during the passage of light from it to the earth. Thus, in the sun the aberration in longitude is 20' constantly, that being the space moved by the earth in 8' 7" of time, the interval in which light passes from the sun to the earth.

**ABETTOR**, in Law, one who encourages another to the performance of some action. In Scots law, *art and part*.

**ABEYANCE**, in Law, the expectancy of an estate: hence we may say, "*suc*" property is in *abeyance*."

**ABIB**, the first month in the Jewish year, commencing at the vernal equinox.

**ABIDING** by *Writings*, in Scots law, compelling a person to abide by a false deed, as if it were true.

**ABINTESTATE**, in Civil Law, applied to the person who inherits the right of one who died intestate, or without will.

**ABJURATION**, an oath disclaiming all allegiance with a pretender: the Abjuration of *heresy*, is the solemn recantation of any doctrine as false.

**ABLACTATION**, in Gardening, the method of grafting by approach; *i. e.* the scyon of one tree is for some time joined to the stock of another, and afterwards cut off and weaned from the parent tree.

**ABLAQUEATION**, in Gardening, the operation of exposing the roots of trees in winter, to the air, rains, snows, &c.

**ABLUTION**, in a general sense, washing; in a religious one, the purifying of the body by water before the performance of some act of devotion. Ablutions are commanded by the Mosaic law; enjoined by the Pagan ritual; and practised by the Moslems, agreeably to the dictates of Mahomet. The priests of Egypt used daily ablutions; the Grecians, sprinklings; the Romans, lustrations; the Jews, washings and baptisms. The ancient Christians had their ablutions before communion; the Roman Catholic has his before mass, sometimes after. On Good Friday, the Syrians, Copts, &c. have solemn washings.

**ABOARD**, the inside of a ship: hence the phrase, *to go on board*;—*to board*, to enter a ship *vi et armis*, by force and arms;

—to fall aboard, to encounter. *Aboard main tack*, the order to draw the main tack; i. e. the lower corner of the main-sail down to the chess-tree.

**ABOLITION**, in Law, the repealing of any statute. 2. Remitting the punishment of a crime. 3. Leave given a criminal accuser to desist from further prosecution of the accused.

**ABOMASUS**, the fourth stomach of ruminating animals. In calves, the runnet or earning is formed in the Abomasus.

**ABOMINATION** of *Desolation*, foretold by Daniel, the statue of Jupiter Olympius, which Antiochus Epiphanes caused to be put up in the holy temple of Jerusalem. And the *Abomination of Desolation*, mentioned by the Evangelists, signifies the ensigns of the Romans, when Jerusalem was besieged by Titus, the son of Vespasian.

**ABORIGINES**, the primitive inhabitants of a country; as the blacks of Africa, the Indians of America.

**ABORTION**, the premature exclusion of a foetus. The horrid crime of procuring abortion was prohibited by Solon and Lycurgus; allowed by the Romans till the time of the emperors Severus and Antonine; and practised by dispensation under the Roman ecclesiastical law!

**ABOUT Ship**: the order to the ship's crew for tacking. The situation of a ship immediately after she has tacked.

**ABRAHAMITES**, an order of monks, exterminated by Theophilus in the 9th century. Also the name of another sect of heretics, who had adopted the errors of Paulus, and who were thence called Paulicians.

**ABRASAX**, the supreme God of the Basilidian heretics; i. e. of the 365 heavens, or 365 revolutions of the earth on its axis. In each of those heavens was placed an angel of intelligence, that created it, and each angel was created by that immediately above it, till the scale reached the first Creator.

**ABRASION**, in Medicine, the effect of sharp corrosive medicines in humours, in wearing away the natural mucus that covers the intestines and stomach.

**ABRAUM**, a red clay brought from the Isle of Wight, with which cabinet-makers darken and polish mahogany. The best thing for polishing mahogany is, after all, linseed oil, and regular rubbing with a piece of flannel.

**ABREAST**, a Sea term, side by side, or opposite to, as when two ships have their sides parallel, and heads equally advanced. In line *abreast*, a fleet advances uniformly, equally distant and parallel, the length of each ship forming a right angle with the extent of the squadron. The commander is then in the centre. *Abreast*, within ship, on a line with the beam, main hatchway, &c. From this point we reckon our position *fore* or *aft*, as we stand between the beam and the bows, or stern.

**ABRIDGMENT**, the reduction of any thing into a smaller compass.

**ABROGATION**, in Law, the act of abolishing, by authority of the law maker.

**ABROMA**, in Botany, a stove bark tree, that grows freely in common garden soil, and may easily be propagated by seeds or cuttings.

**ABRUS**, in Botany, the knobbed-rooted wild liquorice.

**ABSCISS**, in Surgery, a collection of puriform matter in a part; properly, a cavity containing pus, or matter.

**ABSCISS**, **ABSCISSA**, **ABSCISSÆ**, in Conics, is any part of the diameter or axis of a curve, comprised between any fixed point, where all the abscisses begin, and another line called the ordinate, which is terminated in the curve. Commonly the abscisses are considered as commencing at the vertex of the curve; but this is not necessary, as they may have their origin in any other point; but generally, when no condition is specified, they are understood as commencing at the vertex. Thus, if AQ be any curve, and A, or A', or A'', certain fixed points, of which, in the annexed figures, A and A' are at the vertices, but A'' any point whatever in the axis; also PQ any line perpendicular, or otherwise, to the axis A, A', and terminating in the curve; then is PQ

an ordinate, and AP, A'P, A''P, abscisses. The absciss and corresponding ordinate, considered together, are, by Geometricians, called co-ordinates, and by means of these the equation of the curve is defined. See CURVE.

**ABSCONSA**, a dark lantern, used by the Monks in burying the dead at night.

**ABSENCE**, in Law, non-appearance when cited before a court. No person can be tried criminally in absence.

**ABSINTHIATED**, in Medicine, tinged with wormwood, or absinthium. The wormwood wine of the ancients, infused in draughts, proved beneficial in cases of indigestion, or debility of the stomach.

**ABSIS**, in Astronomy, the same with *apsis*, those two points of a planet's orbit, where it is at its greatest and least distance from the sun, &c. The line connecting these points is called the line of the apsides. The apsis at the greatest distance from the sun is called the *aphelion*, at the greatest distance from the earth, the *apogee*; at the least distance from the sun, the *perihelion*; at the least distance from the earth, the *perigee*.

**ABSOLUTE Term or Number**, in Algebra, is that which is completely known, and to which all the other part of the equation is made equal; thus in the equation  $x^2 + ax = b$ , the latter quantity  $b$ , is called the absolute term, which in every equation is equal to the continued product of all its roots.

**ABSTRACT**, or *Pure*, **MATHEMATICS**, treat of the properties of magnitude, figure, or quantity, absolutely and generally considered, without restriction to any species in particular, such as Arithmetic and Geometry. It is thus distinguished from *Mixed Mathematics*, in which simple and abstract quantities, primitively considered in Pure Mathematics, are applied to sensible objects, as in Astronomy, Mechanics, Optics, &c.

**ABSTRACT Numbers**, are assemblages or units, considered independently of any things, that they might otherwise be supposed to represent. For example, 5 is an abstract number, while it remains independent; but if we say 5 feet, or 5 miles, it is no longer an abstract, but a *concrete* number.

**ABSOLUTION**, in Civil Law, a sentence pronouncing an accused person innocent. In Canon law, the judicial act whereby the priest declares the sins of such as are penitent to be remitted.

**ABSORBENT**, swallowing up. Absorbent medicines are testaceous powders, or calcareous earths, as chalk, &c. which, taken inwardly, dry up acid and redundant humours in the stomach.

**ABSORBENTS**, or Absorbing Vessels, in Anatomy, are the lacteal, lymphatic, and inhalent arteries, which imbibe all those fluids that come in contact with them; but are themselves so minute as to escape observation in ordinary dissections.

**ABSTRINGENT Medicines**, such as are used for resolving obstructions, concretions, &c. such as soap, &c.

**ABSURD**, or **ABSURDUM**, a term employed in demonstrating converse propositions, in which the proposition is not proved in a direct manner, by principles before laid down; but it proves that the contrary is absurd, or impossible; and thus indirectly demonstrates the truth of the proposition itself. The 4th proposition of the 1st book of Euclid is demonstrated by this method, by shewing, that if the extremities of two right lines coincide, the lines themselves will coincide in all their parts, otherwise they would enclose a space, which is *absurd*, being contrary to the 10th axiom. Converse propositions are commonly proved in this way, which is called *reductio ad absurdum*: but it is unsatisfactory; yet it would be difficult to devise any system of geometry in which such a method should be entirely excluded.

**ABUNDANT Number**, in Arithmetic, a number, the sum of whose aliquot parts is greater than the number itself: thus, 12 is an abundant number; for the sum of its aliquot parts  $1+2+3+4+6=16$ , which is greater than 12. It is thus distinguished from a perfect number, which is equal to the sum of

all its aliquot parts, and from a deficient number, which is less than the sum of all its aliquot parts.

ABYSS, something profound, and, as it were, bottomless, as the ocean, hell; but more properly, the temple of Proserpine, on account of the vast treasures there deposited.

ABYSS, in Heraldry, the centre of an escutcheon; hence the phrase, "he bears azure, a flower-de-lis, in abyss;" i. e. in the middle of the shield, clear from every other bearing.

ACACIA, in Botany, the Egyptian thorn, one of the handsomest trees that adorn our pleasure-grounds. Cuttings strike in sand, under a hand-glass, in the bark bed. Of the flowers of a species of the Acacia, the Chinese make a fine yellow dye. The process is merely boiling and extraction, with the addition of a small quantity of alum, and oyster shells calcined.

ACACIA, in the Materia Medica, is a mild astringent, useful in the spitting of blood; imported from Egypt, and simply the inspissated juice of unripe sloes.

ACADEMY, a School, or place of learning; a collegiate seminary; a riding-school, &c.; a society of learned men, established for the improvement of the sciences, arts, &c.

ACANTHA, the prickly of a plant, or spine of a prickly fin on a fish.

ACANTHABOLUS, in Surgery, an instrument for pulling thorns and the like out of the skin.

ACANTHUS, in Botany, the plant bear's breech, which, as a dye, gives a fine yellow; in Architecture, an ornament representing the leaves of the Acanthus, and decorating the capitals of the Corinthian and Composite orders.

ACARAUNA, a small American fish, called, by our sailors, *old wife*.

ACARUS, the tick, or mite.

ACATHARSIA, an impurity of the blood and humours.

ACAULIS, applied to those plants whose flowers are without stalks, and rest on the ground, as the *Carlina thistle*.

ACCAPITARE, in Law, the act of becoming vassal of a lord, or of yielding him homage or obedience; hence *Accapitum*, or money paid by a vassal upon his admission to a feu.

ACCEDAS *ad Curiam*, a writ lying where the man has received, or fears, false judgment in an inferior court.

ACCELERATION, in Mechanics, the increase of velocity in a moving body. *Accelerated* motion is that in which the velocity is continually increasing, from the continued action of the motive power. *Uniformly accelerated* motion, is that in which the velocity increases equally in equal times. The increasing velocity with which a body falls to the earth, is an instance of accelerated motion, which is caused by the constant action of gravity. A cannon-ball is acted on by a single impulse of the powder, and the accelerating force of gravity; it therefore describes a curve: this is the foundation of the art of gunnery. A new impression being made upon a falling body at every instant, by the continued action of gravity, and the effect of the former still remaining, the velocity continually increases. Suppose a single impulse of gravitation, in one instant, to give a falling body one degree of velocity; if after this the force of gravitation were suspended, the body would continue to move with the same degree of velocity, without being accelerated or retarded. But because the attraction of gravitation continues, it produces as great a velocity in the second instant as in the first; which, added to the first, makes the velocity in the second instant double the first. In like manner, in the third instant, it will be tripled; quadrupled in the fourth; and in every instant, one degree of velocity will be acquired, and added to that which the body had before; that is, the motion will be uniformly accelerated.

Hence, then, from the preceding principles and reasoning, we deduce the following general laws of uniformly accelerated motions; viz.

The velocities acquired are constantly proportional to the times.

The spaces are proportional to the squares of the times; so that if a body describe any given space in a given time, it will describe four times that space in a double time, nine times that space in a treble time, and so on. And universally, if the times be in arithmetical proportion, as 1, 2, 3, 4, &c. *t*, the spaces described will be as 1, 4, 9, 16, &c., *t*<sup>2</sup>. Thus a body, which falls by gravity through 16½ feet in the first

second, will fall through 64½ feet in two seconds, and so on. And since the velocities acquired in falling are as the times, the spaces will be as the square of the velocities; and both the times and velocities will be as the square roots of the spaces.

The spaces described by a falling body in a series of equal moments, or intervals of time, will be as the odd numbers, 1, 3, 5, 7, 9, &c. which are the differences of the squares or whole spaces; that is, a body which falls through 16½ feet in the first second, will fall through  $3 \times 16\frac{1}{2}$  in the second,  $5 \times 16\frac{1}{2}$  in the third, and so on.

ACCELERATION of Bodies on Inclined Planes. The same general law prevails here as in perpendicularly falling bodies; the plane merely making the motion slower; but the inclination being every where equal, the retardation arising therefrom will proceed equally in all parts at the beginning and the ending of the motion: and the ACCELERATION of the Motion of Pendulums, is in a less ratio than that of bodies falling perpendicularly. The ACCELERATION of the Moon, is her increase of mean motion, from the sun, compared with the diurnal motion of the earth; being about 10" in 100 years.

ACCELERATION of a Planet, when the real diurnal motion exceeds the mean diurnal motion. And a planet is retarded when the mean motion exceeds the real diurnal motion. This inequality arises from the change in the distance of the planet from the sun, which is continually varying; the planet moving quicker in its orbit when nearer the sun, and slower when further from him.

ACCENT, in Speaking, an inflexion of voice; in Grammar, a certain mark placed over a word or syllable.

ACCEPTANCE, in Law, agreeing to offers made in bargaining; in Commerce, signing one's name, or making one's self debtor for the sum contained in a bill of exchange.

ACCEPTILATION, among Civilians, a discharge given by a creditor to the debtor, without the payment of any value.

ACCESSION, in Law, the property of the accessory, as the calf of a cow becomes the property of her owner. Accession in Medicine, the paroxysm of a disease; in Politics, it signifies a prince's succeeding to the throne of his father or predecessor.

ACCESSORY, something that accedes, not principal: guilty by participation, *before* or *after* the fact.—ACCESSORY Nerves, in Anatomy, arise from the medulla in the vertebrae of the neck, pass through the skull, and distribute themselves again in the neck and shoulders.—ACCESSORY, in Painting, denotes arms, vases, &c. which in historical pieces may be left out.

ACCIDENT, in Heraldry, an additional point in a coat of arms, which may be omitted or retained, without altering the essence of the armour.

ACCIDENTAL Point, in Perspective, is a point in the horizontal line, in which a right line drawn from the eye, parallel to another right line, intersects the picture or perspective plane. This is also the accidental point of all other lines parallel to the original line, since the same line drawn from the eye is parallel to them all; and the representations of all these parallels, when produced, concur in the accidental point. See PERSPECTIVE.

ACCLIVITY, the slope or steepness of a line or plane inclined to the horizon, taken upwards, in contradistinction to declivity, which is taken downwards. So the ascent of a hill is an *acclivity*, and the descent of the same a *declivity*.

ACCOMPANIMENT, in Music, an instrument that accompanies the voice to give it effect, or make the music more full. In Painting, such objects as are added for ornament or fitness to the chief figures, as dogs, guns, &c. In Heraldry, any thing added to the shield for ornament, as the belt, mantling, supporters.

ACCOMPLICE, an accessory, privy to a crimewith another. ACCOMPLISHMENT of PROPHECY, the fulfilment, under the New Testament, of events foretold by the Jewish prophets under the Old Testament.

ACCORD, in Painting, the harmony that prevails among the lights and shadows of a picture.

ACCOUNT, or ACCOMPT, a computation or reckoning of any thing by numbers, as a transaction in business: and ACCOUNTANT is a person skilled in accounts; or a bookkeeper to the South Sea or East India Company.

**ACCUMULATION** of Degrees, in an University, the taking of several degrees together; or at shorter intervals than the rules of the academy allow.

**ACE**, a card or die with one point only.

**ACENTATUM**, or **ACENTETA**, a name given by the ancients to the purest and finest kind of rock crystal. In the isle of Arran, there are found rock crystals that vie with Brazilian diamonds.

**ACER**, in Botany, the *Maple* or *Sycamore Tree*. See **MAPLE**.

**ACETABOLUM**, in Anatomy, a cavity in any bone, for receiving the protuberant head of another. In Botany, the trivial name of a species of the peziza, or cappeziza, a genus belonging to the cryptogamia fungi of Linnæus.

**ACETOSA**, Sorrel.—**ACETOSELLA**, a species of *oxalis*.—**ACE-TOUS**, partaking of the nature of vinegar.

**ACETATE** of **POTASH**, known also as *regenerated tartar*, *essential salt of wine*, &c.: may be formed by saturating carbonate of potash with distilled vinegar, and by evaporating the solution slowly to dryness. This salt has a pungent alkaline taste; exposed to the air, it becomes moist; is soluble in water; when heated, it melts and froths up, and is then decomposed and charred.

**ACETUM**, vinegar, the vegetable acid of chemists.

**ACHAN**, in Medicine, a species of *herpes*.

**ACHARNER**, a star of the first magnitude in the constellation Eridanus.

**ACHILLEA**, an artificial grass, called milfoil, yarrow, and sneezewort. This grass succeeds best in a good lawn; and may be sown 12 lbs. to an acre.

**TENDO ACHILLES**, in Anatomy, a strong tendon of the heel of the foot.

**ACHROMATIC**, a term applied to those telescopes in which the aberrations of light are remedied, and the colours justly reflected.

**ACID** for Punch. Bake red currants, and strain them as for jellies; take a gallon of the juice, put to it two quarts of new milk; crush pearl gooseberries when full ripe, and strain them through a coarse cloth; add two quarts of the juice, and three pounds of double-refined sugar, three quarts of rum, and two of brandy, with one ounce of isinglass dissolved in the liquor: mix it all up together, and put it in a little cask. Let it stand for six weeks, and then bottle it for use. This acid will keep for many years. But, after all, lemon juice is the best acid for punch.

**ACIDS** and their **SALTS**. Acids are either solid, liquid, or gaseous. They have so strong an attraction for water, as to be generally incapable of appearing in a solid form.

*The general characteristic Properties of Acids.*

1. They are sour when applied to the tongue.
2. They change vegetable blues to a red colour.
3. They combine with metals and metallic oxides: among the latter are included earths and alkalis; with all these they form salts.

4. They combine with water in all proportions. In this state, they are said to be diluted. Very many contain oxygen as one of their components: but this substance is by no means a necessary ingredient in acids; for there are several which possess the above properties, which do not contain oxygen.

All the acids combine with the alkalis. These combinations have been termed neutral salts. Example—sulphate of soda, which is produced by a combination of sulphuric acid with soda. These salts are easily formed by art: and nature exhibits a great number, especially of those which are formed by acids of simple radicals; example—sulphate of lime.

Neutral salts are distinguished by two names; one expressing the acid, and the other the alkaline base; example—sulphate of lime is composed of sulphuric acid and lime.

All metallic substances combine with at least some of the acids; example—sulphate of iron is formed by the union of iron with sulphuric acid.

When a metallic substance is put into an acid, the first requisite, in order that it may dissolve, is, that it become oxidated in it, the acid first giving up a part of its oxygen to the metal; or rather, by decomposing water which may be present: the oxygen combining with the metal, whilst the hydrogen is set free.

In metallic solutions, an effervescence, or disengagement of gas, often takes place. The gas disengaged by nitric acid, is nitric gas; that disengaged by sulphuric acid, is sulphurous acid gas, provided this acid has furnished the oxygen; but it is hydrogen gas, if the oxygen has been furnished by the water.

In general, the metals do not take from these acids all their oxygen; they do not reduce the one to azote, and the other to sulphur; but to nitrous gas, and sulphurous acid, which cannot exist but in a gaseous state.

Metallic substances dissolve without effervescence, when they have been previously oxidated; example—white oxide of lead will dissolve in acetic acid when metallic lead will not.

A metal does not dissolve with effervescence in oxygenated muriatic acid, or chlorine.

Silver, mercury, and lead, are not soluble in muriatic acid, when exposed to it in their metallic state; but if previously oxidated, they are exceedingly soluble, and the solution takes place without effervescence.

Table of the chief acids, whose general properties deserve to be known.

#### *I. Mineral Acids*

1. Sulphurous.
2. Sulphuric.
3. Nitrous.
4. Nitric.
5. Muriatic, or Hydrochloric.
6. Chloric.
7. Carbonic.
8. Fluoric.
9. Boracic.

#### *II. Metallic Acids.*

10. Arsenious.
11. Arsenic.
12. Tungstic.
13. Molybdic.
14. Chromic.
15. Columbic.

#### *III. Vegetable Acids.*

16. Acetic, or Acetous.

17. Malic.

18. Oxalic.

19. Citric.

20. Tartaric.

21. Benzoic.

22. Camphoric.

23. Gallic.

24. Succinic.

25. Suberic.

#### *IV. Animal Acids.*

26. Phosphorous.

27. Phosphoric.

28. Bombic.

29. Sebacic.

30. Lactic.

31. Lactic.

32. Saccho-lactic.

33. Uric.

34. Prussic.

35. Pyroligneous.

The salts produced by the union of any acids, which end in *ous*, have their termination in *ite*. Thus, sulphurous acid and potash form sulphite of potash. Neutral salts formed by acids ending in *ic*, have their terminations in *ate*, thus, sulphuric acid and potash form sulphate of potash.

*Sulphurous Acid* is sulphur combined with oxygen, but not to saturation. It is the sulphurous acid gas when absorbed by water. The salts formed by the combination of this acid with different bases, are called sulphites; they are not employed for any useful purpose.

*Sulphuric Acid*, formerly called oil of vitriol, is formed by the combination of sulphur, which is its base, and oxygen. Sulphates are neutral salts, formed by the sulphuric acid with certain bases. Sulphate of potash, formerly called vitriolated tartar, is produced by the combination of the sulphuric acid and potash. It is found frequently in mineral waters. Sulphate of soda, commonly called Glauber's salt, is formed by the combination of soda with the sulphuric acid. The sulphates of iron and copper are used in dyeing, &c. Sulphate of lime, or plaster of Paris, is used for making casts, busts, &c.

*Nitrous Acid* exists in the state of gas, in the form of a red vapour; it is nitrous gas combined with a quantity of oxygen. Nitrous acid is procured from sulphate of iron, deprived of its water of crystallization by heat, and an equal weight of dry nitrate of potash. It may also be obtained by decomposing nitrate of potash, by means of sulphuric acid, with the assistance of heat. The salts formed with this acid are very little known.

*Nitric Acid*. The constituent principles of this acid are oxygen and nitrogen. It differs from the last mentioned acid, only in not having any nitrous gas in a loosely combined state. Oxygen and nitrogen with caloric, form nitrous gas. This gas, with a greater quantity of oxygen, forms nitric acid. Nitric acid is transparent, liquid, and colourless; sold in the shops

by the name of aqua-fortis. It is procured by re-distilling nitrous acid, or at least heating it till it is deprived of its fumes. The combination of nitric acid with different bases, are called *nitrates*. Nitrate of silver is the lunar caustic used by surgeons. It is also used in making indelible ink for marking linen. These salts have the property of detonating with, or inflaming, charcoal, and other easily inflammable bodies, at a red heat. It is upon this property that the composition of gunpowder is founded, which consists of five parts of nitrate of potash, or salt-petre, one of charcoal, and one of sulphur.

*Muriatic or Hydrochloric Acid*, formerly termed marine acid, or spirit of salt, is composed of hydrogen and chlorine. Its combinations with earths, alkalis, and metals, form hydrochlorates or muriates. Muriate of potash, formed by the combination of muriatic acid with potash, is found in sea-water and old plaster: it has a strong, bitter, disagreeable taste. Muriate of soda, (marine, common, or rock salt,) formed by the combination of muriatic acid with soda, is found native in mines, in many places, but particularly in Poland and Hungary. It is also obtained from sea-water by evaporation, &c. Muriate of ammonia, or sal-ammoniac, formed by the combination of muriatic acid with ammonia, is found native in mines, in many parts, particularly in the neighbourhood of volcanoes. Muriate of lime is found in mineral waters of the sea, to which it contributes to give their bitter taste. Muriate of barytes is not known to exist native. Muriate of lead is the pigment or paint known by the name *patent yellow*.

*Chloric Acid*, formerly called oxygenated muriatic acid, is muriatic acid deprived of its hydrogen. It removes the stain of common ink, though it does not affect printer's ink. It is, therefore, used for cleaning books and prints. Half an ounce of minium or red oxide of lead, being added to three ounces of muriatic acid, will render it fit for this purpose. Nitro-muriatic acid, called formerly aqua-regia, is an acid analogous to chloric acid. This acid has the property of dissolving gold and platina, which cannot be acted upon by any other acid. Chlorate of potash, or oxygenated muriate of potash, is made by introducing the chlorine gas into a solution of potash. This salt has the property of detonating with sulphur, charcoal, &c. and has been used for making gunpowder; but the manufacture and use of this powder are very dangerous.

*Carbonic Acid* exists in the gaseous state, and, in combination with different bases, constitutes the salts termed carbonates. Carbonate of potash is made by exposing a solution of potash to the carbonic acid gas until saturated. Carbonate of soda is decomposed by quicklime, by the acids, and by fire, so also is the former carbonate. Carbonate of ammonia, or concrete volatile alkali, may be obtained from any animal substances, but it is not found native; it is a combination of carbonic acid with ammonia. Carbonate of barytes has no taste, is not altered in the air, is almost insoluble in water, but is decomposed by heat, and by all the acids. Carbonate of magnesia, or common magnesia, is obtained by precipitation with the carbonate of soda, from the sulphate of magnesia. It loses its water and acid by calcination, the residue being pure magnesia, sometimes called calcined magnesia.

*Fluoric Acid* is composed of fluorine and oxygen. In a gaseous state, it forms fluoric acid gas; united to water, it constitutes liquid fluoric acid. It exists completely formed in fluat of lime, known under the name of flour or Derbyshire spar. The distinguishing property of the fluoric acid is, its power of dissolving silex, and being employed for etching on glass.

*Boracic Acid* is a concrete acid extracted from borax, a salt brought from India: its base is unknown. Boracic acid exists in brilliant white scales, soft, and unctuous to the touch. Its taste is bitterish, with a slight acidity. Borate of soda, or borax, formed by the combination of the boracic acid with soda, is found in a crystallized state at the bottom of certain salt lakes, in a barren volcanic district of the kingdom of Thibet. A still purer kind comes from China. When reduced into a white opaque light, it is called calcined borax.

*Arsenious Acid* is metallic arsenic, oxygenated in the first degree, and therefore called arsenious acid. The white arsenic of the chemists' shops is chiefly obtained from the arsenical ores of cobalt.

*Arsenic Acid*, produced only by art, appears in the form of a white powder. All the preparations of arsenic are deadly poisons; the hydro-sulphurets are the best antidotes. A weak solution of hydro-sulphuret of potash, soda, or lime, is therefore often administered with success, if given in time, to persons who have been poisoned by arsenic. Sulphurous, mineral, or the Harrowgate water, may also be given. In such cases, oil, milk, butter, &c. which are too often resorted to, should never be employed, if a sulphuret, or hydro-sulphuret, can possibly be procured.

*Tungstic Acid* is procured from a mineral called tungsten, which is a combination of this acid with lime, (tungstate of lime,) or from wolfram, which is this acid united to iron and manganese.

*Molybdic Acid* is molybdena oxygenated; for this metal is susceptible of oxygenation to such a degree as to become a concrete acid.

*Chromic Acid* is found combined with oxide of lead, in the mineral called chromate of lead, or the red lead of Siberia; also united to iron, alumine, and silex, in the substance called chromate of iron. This acid has the peculiar property of forming the most brilliant colours with whatever metal it combines: chromate of lead is an intense yellow, chromate of mercury a brilliant red, and chromate of silver a beautiful violet.

*Columbic Acid* is found in the lately discovered ore called columbium, or columbate of iron.

*Acetic, or Acetous Acid*, exists, mixed with other substances, in common vinegar. Since this acid is very volatile, it is obtained pure by distilling vinegar in a sand-heat. In this state, it is called distilled vinegar. Its base is carbon, hydrogen, and oxygen. The same substances form the bases of the other vegetable acids, but in different proportions. The acetites of potash and soda are obtained by neutralizing the carbonates of these alkalis with acetous acid, and evaporating and crystallizing the solution. Acetate of lead, or sugar of lead, is composed of lead and acetic acid: hence, acetic acid for preparing aromatic vinegar, is usually obtained by pouring sulphuric acid on the sugar of lead in a retort, and distilling the acetic acid in a receiver prepared for the purpose. Here we have an example of decomposition; for the sulphuric acid must combine with the lead before the acetic acid will come over. This distillation must be carried on in a sand-bath. Aromatic vinegar is merely acetic acid with a little camphor and oil of bergamot dissolved in it.

*Malic Acid* is found in the juice of unripe apples, and some other fruits.

*Oxalic Acid* is prepared from sugar by mixing it with nitric acid. It is highly poisonous, and many deaths have occurred, sometimes through the negligence even of druggists, by mistaking it for Epsom salts, which are very like it.

*Citric Acid* is found in the juice of lemons and oranges unripe grapes, and other sour fruits. It is also called concrete lemon juice, and is used for a variety of purposes. It is a very useful substance for taking stains of ink out of linen.

*Tartaric Acid*. The tartar found adhering to wine casks, is a salt composed of a peculiar acid combined with potash, but in such a manner, that the acid is in considerable excess. The salt is known under the name of acidulous tartrate of potash, and the acid which enters into its composition is the tartaric. It is by the combination of this acid with potash, that the acidulous tartrate of potash, usually called cream of tartar, is formed by solution, with subsequent filtration and evaporation.

*Benzoic Acid* is found in the resin, called benzoin, in the balsam of Peru, and some other substances of this kind. It is also found in urine, and other animal substances.

*Camphoric Acid*, is camphor oxygenated to acidity. Camphor is a concrete essential oil, extracted by sublimation from a laurel which grows in China and Japan.

*Gallic Acid* is found in gall-nuts, bark of trees, and in all those vegetables called astringents.

*Succinic Acid* is obtained from amber, and is therefore called also acid of amber. Amber is a bituminous substance of a yellow colour, which is found chiefly on the sea-coast of Prussia. It takes a fine polish, and is used for various ornaments. It is strongly electrical.

*Suberic Acid* exists in cork. It reddens vegetable blues, and has the peculiar property of turning the blue solution of indigo in sulphuric acid, to green.

*Phosphorous Acid*. When phosphorous is burnt slowly, and does not become completely saturated with oxygen, it forms phosphorous acid. Its salts are the phosphites.

*Phosphoric Acid* is phosphorus saturated with oxygen. This acid is obtained from bones, which are composed of phosphate of lime, and gelatine. It may also be obtained by the rapid combustion of phosphorus in oxygen gas.

*Bombic Acid* is obtained from the silkworm. It is very little known.

*Pyroligneous Acid*, obtained by distillation from wood, is sometimes called wood vinegar. This acid is said to preserve animal food for any length of time. The whole carcase of a sheep being immersed in it, was found, upon examination many months afterwards, to be perfectly free from any appearance of putrefaction. A leg of mutton, declared unsaleable by the butchers, being immersed in the pyroligneous acid, was, after a twelvemonth, perfectly sweet, and likely, from its appearance, to continue so many years.

Dr. Jorg, professor of Leipsic, has made many successful experiments of the same nature. He has entirely recovered several anatomical preparations from incipient corruption, by pouring this acid over them. With the oil which is produced from wood by distillation in the dry manner, he has moistened pieces of flesh already advanced in decay; and, notwithstanding the heat of the weather, soon made them as dry and firm as flesh can be rendered by being smoked in the smoking-room. All traces of corruption vanish at once when the vinegar of wood, or the oil of wood, is applied to the meat with a brush. The professor has also begun to prepare mummies of animals, and has no doubt of success. He promises great advantages to anatomy, domestic economy and even to medicine, from this discovery, for the remedy seems very fit to be applied internally and externally in many disorders.

It is made in the large way at an establishment at Battersea, of one uniform strength of 50 degrees, by the new excise autometer. This acid is pronounced to be pure acetic acid, perfectly free from sulphuric and all other mineral acids, and from mucilaginous, earthy, and metallic impurities. It is therefore, when diluted, perfectly wholesome with food, and may be used for all the purposes of vinegar.

The pyroligneous acid admits of being diluted with seven parts of water, which will reduce it to the strength of common distilled vinegar: it is then well qualified for pickling vegetables and fish: the latter, particularly, is found to be preserved longer with this vinegar, and to eat firmer and better than with any other. This acid is bright and colourless as water; but it readily takes any colour or flavour. It will keep for any length of time, in any climate, without losing its strength, or becoming ropy and thick, or mothery, as it is generally termed. At sea, it is particularly useful for the scurvy; and for all medical purposes, it answers the uses of the best distilled vinegar.

*Sebacic Acid*, called also the acid of fat, and obtained from the fat of animals, is concrete, and soluble in water. It is sour, and without odour.

*Laccic Acid*, lately discovered in a substance called white lac, is formed by certain insects of the coccus tribe.

*Lactic Acid* is found in the whey of milk. It is concrete, and liquefies in the air. It is sour, and oxidates the metals.

*Saccho-Lactic Acid*, discovered by Scheele, who obtained it by treating sugar of milk with nitric acid: it is also obtained by treating gum-arabic with nitrous acid.

*Uric Acid*, also called lithic acid, is found in urinary calculi, and in human urine.

*Prussic Acid* is produced by exposing the horns, hoofs, and dried blood of animals, with an equal quantity of fixed alkali, to a red heat. This acid, united to iron, forms that beautiful pigment called Prussian blue. From this salt the acid is frequently obtained, this being the least expensive mode. The pure acid is, perhaps, the most intense poison ever known: a glass rod dipped in it, was inserted in the mouth of a dog, who fell dead, as if struck by lightning, the instant it touched

the poor animal's palate. The dog had been a remarkably strong one.

*ACLOWA*, a plant used by the natives of Guinea to cure the itch. The *ACOUROBA* is famous among them for its cure of the small-pox, which is administered in an infusion of wine.

*ACONITUM*, common blue monk's-hood; every part of the fresh plant is strongly poisonous; the root most so. It is used in medicine.

*ACORN*, the fruit of the oak; upon which both man and beast may live.

*ACORUS*, in Botany, sweet rush; generally looked upon as a carminative and stomachic medicine: in Natural History, blue coral, which grows in form of a tree on the coast of Benin, in Africa.

*ACOUSTICS* is the science which treats of the nature, phenomena, and laws, of the sense of sound. It extends to the theory of musical concord and harmony, and is, therefore, a valuable and interesting science. Sound is considered as arising from vibrations in the air, communicated to it by vibrations of the sounding body, acting in pulsations, or concentric waves, like the surface of water when a stone is thrown into it. A sonorous body, whilst sounding, is unquestionably in a state of vibration, and the air, by similar vibrations, communicates and propagates these vibrations. The principal causes of the variety of sounds, are: *First*, The greater or less frequency of the vibration. *Secondly*, The quantity or force of the vibrating materials. And, *Thirdly*, The greater or less simplicity of the sounds. Hence arise the height, the strength, and the modification, of sounds. The vibrations of a sounding body continue for a longer or shorter time, according as the body is more or less elastic, or as it is thicker or thinner.

*Of the Velocity of Sound*. By experiments, we know that sound travels 1142 feet in a second, or 13 miles a minute: water accelerates its velocity; and all sounds travel at the same rate; the softest whisper flies with the speed of the loudest thunder. The velocity of sound is to that of a brisk wind as fifty to one.

The velocity of sound has been applied to the measurement of distances.

A ship at sea in distress fires a gun, the light of which is seen on shore 20 seconds before the report is heard, therefore it is known to be at the distance of 20 times 1142 feet, or little more than 4½ miles. I see a vivid flash of lightning; and if in three seconds I hear a tremendous clap of thunder, I instantly know that the thunder cloud is only two-thirds of a mile distant. I should therefore retire instantly from any exposed situation. The pulse of a healthy person beats about 76 times in a minute; if, therefore, between the flash of lightning and the thunder I can feel 1, 2, 3, 4, &c. beats of my pulse, I know the cloud is 900, 1800, 2700, 3600 feet from me.

Smooth and clear sounds proceed from bodies that are homogeneous, and of an uniform figure: harsh and rough, or obtuse sounds, from irregular bodies, or such as are made of mixed matter. The strength of sounds is greatest in cold and dense air; and least in that which is warm and rarefied. And under an exhausted receiver, a bell gives no sound. Every point against which the pulses of sound strike, becomes a centre from which a new series of pulses are propagated in every direction. Hence the extraordinary echoes we sometimes hear.

*Of reverberated Sounds*. Sounds, like light, after it has been reflected from several places, may be collected into one point, as into a focus; it will there be more audible than in any other part, even than at the place whence it proceeded. On this principle, the

*Whispering Gallery*, fig. 6, is constructed. Its form is that of a concave hemisphere, as ADC, and if a low sound be uttered at A, the vibrations expanding themselves every way, impinge on the points D, D, D, D, E, E, &c. and from thence to the points F, G, till they all meet in C, where the sound, being collected as in a focus, will be perfectly well heard. Upon this principle, the whispering gallery of St. Paul's Cathedral, London, is constructed.

The *Speaking Trumpet* is constructed on the principle of the reflection of sounds. Thus, the voice discharged

FIG. 6.

at B, fig. 7, is confined within the tube, and the vibrations striking against its hollow sides, are reflected back to the angle of incidence, and fall into the direction of the vibrations that proceed straight forwards. The whole of the vibrations are thus collected at E, and if the ear be situated at or near that spot, the sound is prodigiously increased. The reflected rays fall without, the rays of incidence within, the trumpet. Every one knows the utility of speaking or hearing trumpets, fig. 8, to deaf persons. The reason is obvious; the speaker's voice at the point E, is reflected to the larger end of the trumpet, and passes by the rays of incidence into the ear at B.

Fig. 8.

**Of Echoes.**—An echo is a reflection of sound striking against some object, as an image is reflected in the glass: but it has been disputed what are the proper qualities in a body for thus reflecting sounds. It is in general known, that caverns, grottoes, mountains, and ruined buildings, return this reflection of sound.

We have heard of a very extraordinary echo, at a ruined fortress near Louvain, in Flanders. If a person sung, he heard only his own voice, without any repetition: on the contrary, those who stood at some distance heard the echo, but not the voice; but then they heard it with surprising variations, sometimes louder, sometimes softer, now more near, then more distant. There is an account in the *Memoirs of the French Academy*, of a similar echo near Rouen.

**Philosophical Principle of an Echo.** Fig. 9.—It has been already observed, that every point against which the pulses of sound strike, becomes the centre of a new series of pulses, and sound describes equal distances in equal times; therefore, when any sound is propagated from a centre, and its pulses strike against a variety of obstacles, if the sum of the right lines drawn from that point to each of the obstacles, and from each obstacle to a second point, be equal, then will the latter be a point in which an echo will be heard. Thus, let A be the point from which the sound is propagated in all directions, and let the pulses strike against the obstacles C, D, E, F, G, H, I, &c. each of these points becomes a new centre of pulses by the first principle, and therefore from each of them one series of pulses will pass through the point B. Now if the

several sums of the right lines  $AC+CB$ ,  $AD+DB$ ,  $AE+EB$ ,  $AG+GB$ ,  $AH+HB$ ,  $AI+IB$ , &c. be all equal to each other, it is obvious that the pulses propagated from A to these points, and again from these points to B, will arrive at B at the same instant, according to the second principle; and therefore, if the hearer be in that point, his ear will at the same instant be struck by all these pulses.

Now it appears from experiment, that the ear of an exercised musician can only distinguish such sounds as follow one another at the rate of 9 or 10 in a second, or any slower rate; and therefore for a distinct perception of the directed and reflected sound, there should intervene the interval of about

$\frac{1}{9}$  of a second; but in this time sound describes  $\frac{1142}{9}$  or 127 feet nearly. And therefore, unless the sum of the lines drawn from each of the obstacles of the points A and B, exceeds the interval AB by 127 feet, no echo will be heard at B. Since the several sums of the lines drawn from the obstacles to the points A and B are of the same magnitude, it

appears that the curve passing through all the points C, D, E, F, G, H, I, &c. will be an *ellipse*. Hence, all the points of the obstacles which produce an echo, must lie in the surface of the oblong spheroid, generated by the revolution of this ellipse round its major axis.

**Different Echoes philosophically accounted for.**—As there may be several spheroids of different magnitudes, so there may be several different echoes, of the same original sound. And as there may happen to be a greater number of reflecting points in the surface of an exterior spheroid than that of an interior, a second or a third echo may be much more powerful than the first, provided that the superior number of reflecting points, that is, the superior number of reflected pulses propagated to the ear, be more than sufficient to compensate for the decay of sound, which arises from its being propagated through a greater space. This is finely illustrated in the celebrated echoes at the lake of Killarney in Ireland, where the first return of the sound is greatly inferior to those which succeed it immediately.

From what has been laid down, it appears, that, for the most powerful echo, the sounding body should be in one focus of the ellipse, which is the section of the echoing spheroid, and the hearer in the other. However, an echo may be heard in other situations, but not so favourably, as such a number of reflected pulses may arrive at the same time at the ear, as may be sufficient to excite a distinct perception. Thus a person often hears the echo of his own voice; but for this purpose he should stand at least 63 or 64 feet from the reflecting obstacle, according to what has been said before.

At the common rate of speaking, we pronounce not above three syllables and a half, that is, seven half-syllables, in a second, therefore, that the echo may return just as soon as three syllables are expressed, twice the distance of the speaker from the reflecting object must be equal to 1000 feet; for as sound describes 1142 feet in a second,  $\frac{1}{2}$  of that space, that is, 1000 feet nearly, will be described, while six half, or three whole syllables are pronounced; that is, the speaker must stand 500 feet from the obstacle. And in general, the distance of the speaker from the echoing surface, for any number of syllables, must be equal to the seventh part of the product of 1142 feet multiplied by that number.

In churches, we never hear a distinct echo of the voice, but a confused sound when the speaker utters his words too rapidly; because the greatest difference between the direct and reflected courses of such a number of pulses as would produce a distinct sound, is never in any church equal to 127 feet, the limit of echoes. But though the first reflected pulses may produce no echo, both on account of their being too few in number, and too rapid in their return to the ear; yet it is evident, that the reflecting surface may be so formed, as that the pulses which come to the ear after two reflections or more, may, after having described 127 feet or more, arrive at the ear in sufficient numbers; and also so nearly at the same instant of time, as to produce an echo, although the distance of the reflecting surface from the ear be less than the limit of echoes. For example, as you enter a small grotto, on the banks of the Dinan, about 2 miles from Castlecombe, in the county of Kilkenny, and continue speaking aloud, no return of voice is perceived; but on arriving at a certain point in the cave, about 14 or 15 feet from the reflecting surface, a very distinct echo is heard. This echo is produced solely by those pulses of voice, which, after being reflected several times from one side of the grotto to the other, (as you observed in the hollow tube of the trumpet,) and having run over a greater space than 127 feet, arrive at the ear in considerable numbers, and no more distant from each other, in point of time, than the ninth part of a second.

**The Invisible Girl**, a deception connected with the conveyance of sound, is an acoustic experiment, which may thus be scientifically and familiarly explained.

In the centre of a large room is placed an apparatus, as fig. 10, with a railing surrounding it, about five feet high, and as many wide. A, A, A, A, are the posts united by the cross-rail B, B, near the top, and by two more similar rails near the bottom. The plume and globe are supported by four stout brass wires. The globe, or ball of copper, is about 12 inches

diameter; and the ribbons which suspend it to the bent wires seem to cut off all communication with the frame.

FIG. 10. Apparatus of the Invisible Girl.

Round this ball are placed four trumpets, at right angles to each other, as shewn in fig. 11, having their mouths opening

FIG. 11. Frame

externally. Nothing more appears in the room, and it is pretended there is within the globe a little lady, who will answer you any question you choose to propose to her; and the process is this:—

When the question is proposed, and uttered into the mouth of one of the trumpets, an answer immediately proceeds from all the trumpets, so distinctly loud as to be heard by an ear applied to any one of them, and yet so remote and feeble, that it actually seems to issue from the twelve-inch globe. But the deception is this: Fig. 12 represents a section of the

FIG. 12.

apparatus, in which one of the posts, and one half of the rail joined to it, are hollowed into a tube, the end of which opens on

the inside of the rail opposite the centre of the trumpet on that side. This hole is concealed by mouldings, &c.; the tube communicates with a tin pipe *p, p*, half an inch diameter, concealed below the floor of the room *f, f*, and passing up the wall to a large deal case, *h*, almost similar to an inverted funnel, and large enough to contain the confederate or invisible girl, and a piano on which she plays. A small hole, closed with glass, is left through the funnel and side-wall of the room, as at *h*, which allows her to comment on what is passing among the company. Thus, when any question is asked at one of the trumpets, the sound is conveyed through the communicating tubes into the funnel-shaped case, so as to be heard by the confederate, who then gives the answer, which in like manner is conveyed through the tube, below the floor, to one of the trumpets, and is heard either from that, or any of the rest.

#### PHILCSOPHICAL ACOUSTIC EXPERIMENTS.

1. *The Æolian Harp*, fig. 13, is so named from Æolus, the heathen deity of winds, as it produces its wild and often exquisite strains, merely by the action of the wind. It is thus constructed:—Let a box be made of as thin deal as possible, of the exact length answering to the width of the window in which it is intended to be placed, five or six inches deep, and seven or eight inches wide; let there be glued upon it two

FIG. 13.

pieces of wainscot, *AB, CD*, about half an inch high, and a quarter of an inch thick, to serve as bridges for the strings; and, within side, at each end, glue two pieces of beech, about an inch square, of length equal to the width of the box, which are to sustain the pegs: into these fix as many pins, such as are used in a harpsichord, as there are to be strings in the instrument, 7, 10, or 15,—half at one end and half at the other, at equal distances: it now remains to string it with small catgut, or blue first fiddle-strings, fixing one end to a small brass pin, and twisting the other round the opposite pin. When these strings are tuned to one and the same note, and the instrument placed with the strings outward in the window to which it is fitted, it will, provided the air blows on that window, give a charming sound like a distant choir, increasing or decreasing according to the strength of the wind. The figure represents an instrument with ten chords; some musicians direct the two extreme chords to be two octaves below the central ones. And here it may be proper to remark, that two strings, of equal length, tension, and thickness, by performing their vibrations together, will sound the same note, or be in unison. Two pipes of the same length and diameter will agree in the same manner. Large instruments and long strings produce grave or deep tones; small instruments and short strings produce acute and high tones.—In the case of the strings, the air is struck by the body, and the sound is excited by the vibrations: in that of the pipes, the body is struck by the air, but, as action and re-action are equal, the effect is the same. Let a musical string of any length be divided into two equal parts by a bridge in the middle; and the sound of each half is eight notes, or an octave, higher than the tone of the whole string. Organ pipes produce grave or acute tones in proportion to their length and size. It is the shortest string of a harpsichord which yields the highest notes.

2. *The Conversing Statue*, fig. 14, consists of a concave mirror, about 2 feet diameter, as *AB*, placed in a perpendicular direction; the focus of the mirror being from 15 to 18 inches from the surface. At the distance of 5 or 6 feet is a partition, with an opening *EF*, of the same size with the mirror;

Christian era: Among the spurious Acts of the Apostles, we may reckon, 1. The Acts of Abdias, bishop of Babylon; 2, the Acts of St. Peter; 3, the Acts of St. Paul; 4, of St. John; 5, of St. Andrew; 6, of St. Thomas; 7, of St. Philip; and, 8, of St. Matthias.

ACTÆA, a plant producing bane-berries, whose juice gives a fine deep black, if fixed with alum.

ACTION, in Painting and Sculpture, is the attitude or position of the several parts of the face, body, and limbs, to shew that the subjects are really actuated by the passions.

ACULER, in the Manege, the motion of a horse, when, in working upon volts, he goes not forward enough at each movement, so that his shoulders are not advanced enough, and his croup comes too near the centre of the volt.

ACUTE ANGLE, an angle less than a right angle. *Acute-angled*,  $\Delta$ , a triangle having all its angles acute. *Acute-angled cone*, a right cone whose axis makes a right angle with its side. *Acute tone*, in Music, a tone high or sharp in comparison of some other tone. *Acute*, in diseases, such as come rapidly to a crisis.

AD VALOREM, in Commerce, according to value.

ADAGIO, in Music, softly, leisurely.

ADAMI POMUM, a protuberance in the forepart of the throat, formed by the *os hyoides*, and vulgarly attributed to a piece of the forbidden apple that stuck in our great progenitor's throat.

ADANSONIA, a plant, the Ethiopian sour-gourd.

ADATAIS, a very fine muslin of India.

ADDEPHAGIA, the disease of gluttony.

ADDER, the viper. *Adder-stung*; for the cure of such bites, some use ointment made of dragon's blood, with a little barley meal and the whites of eggs. *Adder wort*, the same as snakeweed.

ADDITION, the joining or uniting of two or more things together; or the finding of one quantity equal to the sum of any number of other things taken together.

ADDITION, in Arithmetic, is the first of the four fundamental rules of that science; and consists in finding a number equal to several others taken together; which number is generally called the *sum*. Addition is either simple or compound; the first relates to quantities which are all of the same kind or denomination; and the latter, to quantities of different denominations.

*Simple ADDITION*, is the method of collecting several numbers of the same denomination into one sum.—*Rule 1*. Place the numbers under each other, so that units may stand under units, tens under tens, and hundreds under hundreds, and so on; drawing a line below them.

2. Add up the figures in the row of units, and find how many tens are contained in their sum. 3. Set down what remains above the tens, or, if nothing remains, a cipher; and carry as many units as there are tens, to the next row. 4. Add up the second row, together with the number carried, in the same manner as the first; and proceed thus till the whole is finished.

*Proof of Addition*. Cast up the several lines a second time, omitting one of them; and, finally, add the line thus omitted to the sum of the other quantities; and if in this manner the same result is obtained as in the first operation, it is highly probable that the work is right. Other methods of proof may be seen in most authors on this subject.

*Compound ADDITION*, is the method of collecting several quantities of different denominations into one sum.—*Rule 1*. Place the quantities so that those of the same denominations stand directly under each other; and draw a line below them. 2. Add up the figures in the lowest denomination, and find how many units of the next higher denomination are contained in their sum. 3. Write down the remainder, and carry these units to the next higher denomination; which add up in the same manner as before: and thus proceed through all the different denominations to the highest; and this sum, together with the several remainders, will give the answer required.

|                   | £.  | s. | d.  |                   | Yds. | Ft. | In. |

|                   | 19  | 13 | 6¼  |                   | 20   | 0   | 0   |
|                   | 25  | 10 | 6   |                   | 18   | 2   | 9   |
|                   | 59  | 15 | 8   |                   | 16   | 1   | 7   |
|                   | 42  | 12 | 9   |                   | 19   | 0   | 5   |
|                   | 351 | 6  | 2   | Sums              | 136  | 2   | 7½  |

The method of proof is the same as in the former rule.

*ADDITION of Fractions*, is the adding into one sum several fractions of the same, or of different denominations.—*Rule 1*. If the fractions are of different denominations, they must be first reduced to the same denomination. 2. Reduce all mixed numbers to improper fractions; and all fractions, having different denominators, to the same denominator. 3. Add all the numerators into one sum; which, placed over the common denominator, will be the answer required.

*Examples*.—1. Add together the fraction  $\frac{1}{2}$ ,  $\frac{1}{3}$ , and  $\frac{1}{4}$ .

First,  $\frac{1}{2} = \frac{35}{70}$ ;  $\frac{1}{3} = \frac{14}{70}$ ;  $\frac{1}{4} = \frac{10}{70}$ ; then,  $\frac{35}{70} + \frac{14}{70} + \frac{10}{70} = \frac{59}{70}$ .

2. Required the sum of  $\frac{3}{4}$  of a shilling,  $\frac{1}{4}$  of a guinea, and  $\frac{1}{2}$  of a pound.

$\frac{3}{4}$  of a guinea =  $\frac{63}{4}$  of a shilling,  $\frac{1}{4}$  of a pound =  $\frac{35}{2}$  of a shilling.

Therefore,  $\frac{63}{4} + \frac{35}{2} = \frac{126}{8} + \frac{175}{8} = \frac{301}{8} = 37\frac{5}{8}$ .  
= £1. 13s. 11d.—For the method of reducing the fractions, see REDUCTION.

*ADDITION of Decimals*, is finding the sum of several quantities, consisting partly of integers and partly of decimals, or of decimals only.—*Rule 1*. Arrange all the quantities, so that the several decimal points may fall in a line directly under each other. *Example 1.* *Ex. 2.*  
2. Add up the several lines as in simple addition, and place the decimal point in the result exactly under those in the numbers proposed, and it will be the sum required.  
34.17      .1176  
19.143      .1344  
167.13      .744  
143.5      .1468  
363.943 Sums. 1.1428

*ADDITION of Circulating Decimals*, is the finding the sum of any number of circulating decimals.—*Rule 1*. Reduce all the decimals to their equivalent fractions; and the sum of these will be the fractions required.—*Rule 2*. Carry on the repetends till they become conterminous; that is, till they all begin their periods of circulation in the same line, and let also the circulation of each be carried two figures beyond this place: then add as above, but do not set any figure down in the first two places: carry their proper number, however, to the conterminous period, and the result will give the true period of circulation in the sum required.

*Example.* Add 3.6; 78.3476; 4284; 15.5 together.

|         |   |            |    |
|---------|---|------------|----|
| 3.6     | = | 3.6666666  | 66 |
| 78.3476 | = | 78.3476476 | 47 |
| 42.84   | = | 42.8484848 | 48 |
| 15.5    | = | 15.5000000 | 00 |

The Sum..... 140.3627991

*ADDITION*, in Algebra, is finding the sum of several algebraic quantities, and connecting those quantities by their proper signs.

*Case 1*.—When the quantities have like signs, add all the co-efficients, and annex the common letter or letters, and prefix the common sign.

|      | <i>Example.</i>   |
|------|-------------------|
| 6 a  | 3 a + 2 x — 46    |
| 8 a  | 2 a + 3 x — 36    |
| 10 a | 12 a + 17 x — 186 |
| 18 a | a + x — 6         |
| 42 a | 18 a + 23 x — 274 |

**Case 2.**—When the quantities are alike, but have unlike signs, collect the positive co-efficients into one sum, and the negative ones into another. From the greater of these sums subtract the less, and to the remainder prefix the sign of the greater, and annex the common letters. If the aggregate of the positive terms be equal to that of the negative ones, their sums will be  $= 0$ .

*Examples.*

|            |                    |
|------------|--------------------|
| 1.         | 2.                 |
| $-3x + 4$  | $-7ab + 3bc - xy$  |
| $+ x - 5$  | $- ab + 2bc + 4xy$ |
| $-5x + 1$  | $3ab - bc + 2xy$   |
| $+ 2x - 4$ | $-2ab + 4bc - 3xy$ |
| $-4x + 13$ | $5ab - 8bc + xy$   |
| $-9x + 9$  | $-2ab * + 3xy$     |

The manner in which we generally calculate a person's property, is an apt illustration of this rule. We denote what a man really possesses by positive numbers, using the sign  $+$ ; whereas his debts are represented by negative numbers, or the sign  $-$ , affecting those numbers. When it is said of any one that he has 100 crowns, but owes 50, his real possession amounts to  $100 - 50$ , or, which is the same thing  $+ 100 - 50$ , that is to say, 50. And if he has in possession 20 crowns, but owes 20, his real possession amounts to  $20 - 20$ , or  $+ 20 - 20 = 0$ . He has nothing; but owes nothing. But, on the other hand, if he owes 70 crowns, and has in his possession only 40, his real property would be expressed thus  $- 70 + 40$ . Here his debt is represented by the negative number  $- 70$ , while his real possession is represented by the positive number  $+ 40$ . He has 30 crowns less than nothing; and we might express the state of his finances  $- 30$ ; for if any one were to make him a present of 30 crowns to pay this debt, or  $- 30$ , he would only be at the point nothing (0), though really richer than when  $- 30$  stood against his future prospects and exertions. Debts, or money owing, are therefore as much real sums of money as credits, and the sign  $+$ , or  $-$ , governs the quantity or number that follows it.—In the language of Algebra,  $a$  and  $b$  may stand for any two numbers whatever, and therefore,  $a + b$  stands for  $a$  made more by  $b$ . Again,  $a - b$  stands for  $a$  made less by  $b$ ; that is, for the difference of  $a$  and  $b$ , (where  $b$  is supposed less than  $a$ ). Now, by the rule of Case 2,  $a + b$  and  $a - b$ , added together, make twice  $a$  ( $2a$ ); therefore we derive this *Theorem*: If the sum and difference of any two numbers be added together, the whole will be twice the greater number; for if  $a + b$  be added to  $a - b$ , the sum is  $2a$ .

**ADDITION of Algebraic Fractions**, is finding the sum of any number of fractions expressed by means of intermediate letters.—*Rule*. Reduce all the given fractions to a common denominator, and then add the numerators together for the sum required.

*Example 1.* Add together  $\frac{5a}{6b^2} + \frac{3a^2}{4b} + \frac{5c}{12b^3}$

$$\frac{5a}{6b^2} = \frac{10ab}{12b^3}; \quad \frac{3a^2}{4b} = \frac{9a^2b^2}{12b^3}; \quad \frac{5c}{12b^3} = \frac{5c}{12b^3}$$

$$\frac{10ab}{12b^3} + \frac{9a^2b^2}{12b^3} + \frac{5c}{12b^3} = \frac{10ab + 9a^2b^2 + 5c}{12b^3}$$

*Example 2.* Thus also we find,  $\frac{7x}{11y} + \frac{4x}{3y} = \frac{21x}{33y} + \frac{44x}{33y} = \frac{65x}{33y}$

*Example 3.* And,  $\frac{7x + 4y}{3ab} + \frac{5x - 3y}{abc} = \frac{7cx + 4cy}{3abc} \times$

$$\frac{15x - 9y}{3abc} = \frac{7cx + 15x + 4cy - 9y}{3abc} = \frac{(7c + 15)x + (4c - 9)y}{3abc}$$

**ADDITION of Surds**, is the finding the sum of any number of surd expressions, which are inexpressible in rational numbers.—*Rule*. Reduce all the given quantities to their simple form; then add the co-efficients of the equal radicals for the sum required. Thus,

$$\sqrt{8} + \sqrt{18} = 2\sqrt{2} + 3\sqrt{2} = 5\sqrt{2}$$

$$\sqrt{12} + \sqrt{27} = 2\sqrt{3} + 3\sqrt{3} = 5\sqrt{3}$$

$$\sqrt[3]{108a^4} + \sqrt[3]{32a} = 3a\sqrt[3]{4a} + 2\sqrt[3]{4a} = (3a + 2)\sqrt[3]{4a}$$

*Note*. When the quantities are reduced to their lowest terms, or simplest form, and have different radicals, they can only be added together by means of the sign  $+$  placed between them. Thus,  $\sqrt{18} + \sqrt{108} = \sqrt{2} + 6\sqrt{3}$ , cannot be re-

duced to a simpler form than that above; and the same with various others.

**ADDITIONS**, in Heraldry, are things added to arms as marks of honour; as bordure, quarter, canton, gyron, pile, &c.

**ADENANTHERA**, in Botany, bastard flower-fence.

**ADHESION**, in Mechanical philosophy, the same with cohesion, denotes that attraction which takes place between bodies, only when they are at very small distances from each other. See **COHESION**.

**ADIT**, a passage, or entrance. The *adits* of mines are those holes or apertures by which they are entered, or by which the ores and waters are carried away: and the *adit* is sometimes merely an air-shaft.

**ADJUDICATION**, in Scots law, the name of the action by which a creditor attaches the heritable estate of his debtor.

**ADMINISTRATOR**, he to whom the ordinary commits the administration of the goods of a person deceased, in default of an executor.

**ADMIRAL**, a great officer of the navy; the commander-in-chief of a fleet.

**ADORATION**, the act of performing the religious worship of the Almighty.

**ADVANCED Ditch**, in Fortification, that trench which surrounds the glacis or esplanade of a place. *Advanced guard*, the first line of an army; usually a party of horse stationed before the main guard.

**ADYTUM**, the most secret part of a heathen temple.

**ÆGILOPS**, the name of a tumor that sometimes gathers in the great angle of the eye, either with or without inflammation. The method of cure is the same as that of the ophthalmia; but before it has reached the lachrymal passages, it is managed like other ulcers. If the ægilops be neglected, it bursts, and degenerates into a fistula, which eats into the bone.

**ÆGIPHILA**, in Botany, goat's friend.

**ÆGOPODIUM**, small wild angelica, goat wort, or goat's foot.

**ÆOLUS**, in Mechanics, a small portable machine, for refreshing and changing the air in rooms, adapted in its dimensions to supply the place of a square of glass in a sash window; and executed in so small a compass, as to project but a little way from the sash; and in so neat a manner, as to be an elegant ornament to the place where it is fixed. It works without the least noise, requires no attendance, and occasions neither trouble nor expense to keep it in order. It throws in only such a quantity of air as is agreeable; and leaves off working of itself whenever the door or window is opened.

**ÆRA**, in Chronology, or Epocha, is a certain fixed point of time, made famous by some remarkable event, from which, as from a root, the ensuing years are numbered or computed.

1. The *Æra of the Creation*, according to the Jewish calculation, is the year of the Julian period 953, answering to the year 3761 before Christ, and commencing on the 7th of October. Archbishop Usher fixed the creation of the world 4004 years before the birth of Christ.

2. The *Æra of the Olympiads*. This method of computation had its name from the Olympic games, which were celebrated every 4th year, near the city of Olympia, in Peloponnesus. The first Olympiad commenced, according to some chronologers, in the year 3938 of the Julian period; the year from the creation 3174, the year before Christ 774, and 24 years, (as some will have it 23 years,) before the building of Rome. The Olympiads were also called *Anni Iphiti*, from *Iphitus*, who instituted, or at least renewed, the solemnity of the Olympic games. We do not find any computation by Olympiads after the 364th, which ended with the year of Christ 440, except that, in a charter of our king Ethelbert, the years of his reign are said to be reckoned by Olympiads. This method of reckoning was followed by the ancient Greeks.

3. The *Æra of the Building of Rome*; which took place A.M. (i. e. in the year of the world) 3197, and B. C. (before Christ) 752 or 753. This has also been called the *Varronian epocha*, being first introduced by Terentius Varro. The ancient Roman historians usually follow this epoch, which is referred to thus, A. U. C. (that is, *Anno Urbis Condite*, or the Year of Building the City.)

4. The *Æra of Seleucus* was followed by the Syro-Mace-

donians; Seleucus the Great having disused the æra of the Olympiads, and reckoned from the beginning of his own reign, which was twelve years after the death of Alexander. The æra of Seleucus commences with the retaking of Babylon by Seleucus in the year of the world 3692, and before Christ 312.

5. *The Æra of Dioclesian* was introduced in honour of the emperor of that name; it has also been called the *Æra of the Martyrs*, from the vast number of Christians who were put to death during the Dioclesian persecution. This æra commenced in the year of Christ 284, and was long followed in the west.

6. *The Vulgar or Christian Æra*, (or of A. D.) This was not fully settled till the year 527; when Dionysius Exiguus, a Roman abbot, fixed it to the 4713th year of the Julian period, which was four years too late. It is, however, now so generally received, that this gross error in calculation is disregarded.

7. *The Hegira*, or *Turkish Æra*, took its rise from the false prophet Mohammed's flight from Mecca to Medina, on Friday, July 16, A.D. 622. It is a lunar year, beginning with the new moon of that time, which is the reason of the regard for crescents in the East, where they rise on every mosque. In order to know in what year of the vulgar æra any given year of the Hegira falls, the student should reduce the lunar years into solar years, and add the number 622. Thus, the year 1221 of the Hegira corresponds with the year 1806 of the vulgar æra; it commenced on the 21st day of March, 1806, and terminated on the 11th of March, 1807.

8. *The Æra of the French Revolution*.—As this æra is constantly referred to, by French writers, during the period that France was under republican government, a few particulars concerning it may assist the reader's historical studies. The æra in question was substituted for the vulgar or Christian æra, in all public and civil instruments, by virtue of the decree, issued by the National Convention, on the 5th October, 1793. It commenced with the epocha of the foundation of the republic, i.e. on the 22d of September, 1792, of the vulgar æra; on the morning of which day the sun arrived at the true autumnal equinox, at 18 minutes and 30 seconds past nine o'clock. (Paris time.) In the new calendar, the months consisted of 30 days each, divided into three decades; with five intercalary days to complete the year. The names of the months were adapted to the climate of Paris, thus: *Vendémiaire*, or vintage month; *Brumaire*, or foggy month; *Frimaire*, or sleety month; *Nivose*, or snowy month; *Pluviose*, or rainy month; *Ventose*, or windy month; *Germinal*, or budding month; *Floreéal*, or flowery month; *Prairial*, or meadow month; *Messidor*, or harvest month; *Thermidor*, or hot month; and *Fructidor*, or fruit month. This æra (the experiment of an infidel philosophy) was abolished by Buonaparte, and the Christian æra recommenced with 1806.

**AERIAL**, Perspective, is that which represents bodies diminished and weakened in proportion to their distance from the eye; but it relates principally to the colours of objects, which are less distinct the greater the distance at which they are viewed.

**AEROLITHS**, air-stones, a name given to those solid semi-metallic substances which fall from the atmosphere. The descent of such bodies had been long reported; but the fact was not considered authentic till within a few years: it is now so well established, that there is no longer any doubt on the subject, several cases having been attested by eye-witnesses of undeniable veracity. The larger stones have been seen as luminous bodies, moving with great velocities, descending in oblique directions, and frequently with a loud hissing noise, resembling that of a mortar-shell when projected from a piece of ordnance; they are sometimes surrounded with a flame, tapering off to a narrow stream at the hinder part, are heard to explode, and seen to fly in pieces. The velocity with which they strike the earth is very great, frequently penetrating to a considerable depth, and when taken up, have been, in some cases, found to be still hot, and bearing evident marks of recent fusion. Such falls have happened during a thunder storm, or when the sky has been clear and serene; whence we infer that these phenomena are unconnected with the state of the atmosphere. The most remarkable characteristics of these stones is, that they resemble each other; yet they are totally different from any known terrestrial substance; and present,

in all cases, the same appearance of semi-metallic matter, coated on the outside with a thin black incrustation. It is not, however, in appearance only that their similarity is discovered; they have been submitted to chemical analysis, in all cases yielding the same substances, and in very nearly the same proportions. The stone which fell at L'Aigle in France, in 1803, was found to contain 54 parts of silica; 36 of oxyde of iron; 9 of magnesia; 3 of oxyde of nickel; 2 of sulphur; 1 of lime. And all that have been analyzed have given nearly the same results. The specific gravity of these bodies is also nearly the same, exceeding common stone, and approaching that of metallic ores, being about 3.400, or nearly  $3\frac{1}{2}$  times that of common water. These general constant characters indicate a common origin, and hypotheses have been advanced to account for these singular phenomena. Some attribute them to terrestrial, and others to lunar, volcanoes; they have again been supposed to be concretions formed in the regions of our atmosphere; while others have considered them as small planets circulating about the sun or earth, which coming in contact with our atmosphere, take fire from the resistance and friction they experience in passing through it.

With regard to the first supposition, viz. that these stones proceed from terrestrial volcanoes, it will be sufficient to observe, that no remarkable eruption has been known to have happened at or near the time of their fall, and that such bodies have been found at the distance of some thousand miles from any known volcano; besides, the immense force that would be necessary to project bodies, some of them of many hundred weight, to so great a distance, far exceeds any force that we can conceive to arise from volcanic eruptions.—As to the theory, that they proceed from volcanoes in the moon, it has a greater degree of probability. The same force that would project a body from the moon to the earth, would not, if it were exerted at the earth's surface, send the same body to the distance of ten miles; in consequence of the superior gravity of our planet, and the density of the atmosphere. It is computed, that a body projected from a favourable spot on the moon's surface, say the centre of her disc opposite the earth, with a velocity about four times that commonly given to a cannon ball, or, 8220 feet per second, would carry it beyond the centre of attraction, and consequently into the sphere of the earth's activity; whence it must necessarily either fall to the surface of the earth, or circulate about us as a satellite. The time a body, so projected, in its passage from the moon to the earth, would take three days; which is not so long but that it might retain its heat, particularly as it is doubtful whether in passing through a vacuum, or very attenuated medium, it would be possible for the caloric to escape, not to say that it might acquire a fresh accumulation of heat, by passing through the denser parts of our atmosphere. Besides, eruptions, resembling those of our volcanoes, have been frequently observed in the moon, and her atmosphere is extremely rare, presenting but little resistance to projected bodies: it will then be seen that this hypothesis, though apparently extravagant, is much more probable than the one we before examined.—With regard to the theory of these bodies being concretions formed in the air, there is one principal objection, viz. that the velocity with which they strike the earth, estimated by the depth to which they have been known to penetrate, is so great as to indicate their having fallen from heights far exceeding the limits of the terrestrial atmosphere.—It only remains to notice the supposition of their being little planets, which in the course of their revolutions get entangled in our atmosphere, and by the resistance they experience, have their projectile velocity destroyed, which brings them to the earth. On this hypothesis it is difficult to account for the strong appearance of recent fusion that these bodies possess, which can hardly be attributed to the friction experienced in passing through the medium of our air. Besides, it would exhibit the first mark, which any where appears, of want of order, uniformity, and durability, in the works of the Deity: to have this grand machine thus falling to pieces and to decay, from the mere operation of external causes, but ill accords with that wisdom, power, and omniscience, which are so strongly indicated in all the works of the creation. The difficulties, however, are fairly stated, and the reader of course will draw his own conclusions.

The following is an ABSTRACT of a TABLE, drawn up by M. IZARN, a Philosopher, who has paid great attention to this subject; it exhibits a collection of the best authenticated modern instances of these phenomena.

| SUBSTANCES.                                            | PLACES WHERE THEY FELL.            | PERIOD OF THEIR FALL.      | TESTIMONY.              |
|--------------------------------------------------------|------------------------------------|----------------------------|-------------------------|
| Shower of stones                                       | at Rome                            | Tullius Hostilius.         | Livy.                   |
| Shower of stones                                       | at Rome                            | Cons. C. Mar. and M. Torq. | J. Obsequens.           |
| Shower of iron                                         | in Lucania                         | Age of Crassus             | Pliny.                  |
| Shower of mercury                                      | in Italy                           | unknown                    | Dion.                   |
| A very large stone                                     | near the river Negos, Thrace.      | second year 78 Olympiad.   | Pliny.                  |
| Three large stones                                     | in Thrace                          | before Christ 452.         | Ch. of Count Marcellin. |
| Large stone of 260lb.                                  | Ensisheim, Upper Rhine             | November 7, 1492           | Butenschoen.            |
| Mass of iron, 14 quint.                                | Abakank, Siberia.                  | very old.                  | Pallas, Chladni, &c.    |
| About 1200 stones; one of 120lb, }<br>another of 60lb. | Padua, in Italy                    | in 1510.                   | Cardan, Vascit.         |
| Stone of 59lb                                          | On Mount Vaiser Province.          | November 27, 1627.         | Gassendi.               |
| Two large stones                                       | Ireland                            | in 1695                    | Musschenbroeck.         |
| Stone of 72lb.                                         | Macedonia                          | January, 1706              | Paul Lucas.             |
| Shower of sand for 15 hours                            | in the Atlantic.                   | April 6, 1709.             | Père la Feuillée.       |
| Shower of stones                                       | Barboutan, near Roquefort.         | July, 1738.                | Darcet, jun. Lomet, &c. |
| Shower of stones                                       | at Plann, Bohemia.                 | July 3, 1753               | B. de Born.             |

**AEROGRAPHY**, a description of the air, or atmosphere, as to its limits, dimensions, properties, &c.

**AEROMETRY**, the science of measuring the air, its powers, and properties; including the laws of motion, gravitation, pressure, elasticity, refraction, condensation, &c. of the atmospheric fluid. See **PNEUMATICS**.

**AERONAUT**, a person who floats aloft in the air in a balloon.

**AEROSTATION**, the art of navigating the air, both in its principles and practice, in *aerostatic machines*, or *air balloons*.—No discovery was ever made, which drew after it more general admiration, or excited more extravagant hopes, than the art of aerostation; yet, after the lapse of 40 years, slender indeed have been the additions made to science by its discoveries, while humanity has had to mourn over the loss of several individuals of spirit and enterprise.

The Principles of Aerostation are simply these:—1. Any body which is specifically lighter than the air, bulk for bulk, will be buoyed up by it, and ascend, till it enters a stratum of the atmosphere in which the weights are equal, and then it will remain stationary, or float horizontally, or descend. An air balloon, then, is a machine, the whole mass of which is of less specific gravity than the air in which it rises. 2. Heat rarefies, expands, and lessens the specific gravity of air, till its weight is proportional to the heat; and 435 degrees of heat will just double the bulk of a volume of air. If, therefore, the air enclosed in any kind of covering be heated, and consequently dilated, to such a degree as that the excess of the weight of an equal bulk of common air above the weight of the heated air, is greater than the weight of the covering and its appendages, this whole mass will ascend in the atmosphere; till, by the cooling and condensation of the included air, or the diminished density of the surrounding fluid, it becomes of the same specific gravity with the air in which it floats, and without renewed heat it will then gradually descend. If, instead of heating common air, enclosed in any covering, and thus diminishing its gravity, the covering be filled with an elastic fluid lighter than atmospheric air, so that the excess of the weight of an equal bulk of the latter, above that of the enclosed elastic fluid, be

greater than the whole burden of the machine with its accompaniments, the whole mass will mount into the air, as in the former case, and continue to rise in it till it attains an altitude at which the surrounding air is of the same specific gravity with itself.

*Inflammable Air*, for balloons, is obtained by applying acids to metals; or subjecting animal, vegetable, and mineral substances in a close vessel, to a strong heat; or by transmitting the vapour of certain fluids through red-hot tubes; or, finally, from carburetted hydrogen gas, which is nothing more than the smoke of coal purified. In the first of these methods, iron, zinc, and vitriolic acid, are the materials most commonly used: the vitriolic acid must be diluted with about five or six parts of water. Iron may be expected to yield, in the common way, about 1700 times its own bulk in gas: or 4½ ounces of iron, the like weight of oil of vitriol, and 22½ ounces of water, will produce one cubic foot of inflammable air: six ounces of zinc, and an equal weight of oil of vitriol, and 30 ounces of water, are necessary for producing the same quantity. It is more proper to use the turnings or chippings of great pieces of iron, than the filings of that metal; because the heat attending the effervescence will be diminished, and the diluted acid will pass more readily through the interstices of the turnings when they are heaped together, than through the filings, which stick closer to one another. The weight of the inflammable gas thus obtained in the common way, by means of acid of vitriol, is generally about one-seventh of the weight of common air; but with the necessary precautions for philosophical experiments, it will be less than one-tenth of the weight of the same fluid. The other elastic fluids that are generated with the inflammable air, may be separated from it by passing the inflammable air through water in which quicklime has been dissolved; the water will absorb these fluids, cool the inflammable air, and prevent its over-heating the balloon when it is introduced into it. But, at a much cheaper rate, gas for balloons may be had from pit-coal, asphaltum, amber rock oil, oak, and other minerals. A pound of pit-coal exposed to a red heat, yields 3 cubic feet of gas; or, according to Glegg's improvements, one chaldron of Wallsend coals will yield 25,000 cubic

feet of gas; and the specific gravity of this gas is 0.555, atmospheric air being 1; though, in some books, you are told pit coal gas weighs only  $\frac{1}{4}$  of common air.

*To Make the Gas for Balloons.*—Small balloons may be filled with gas, after passing it through water. See the annexed apparatus, fig. 17. A is a bottle that contains the ingredients mentioned above. B, C, is a tube which conveys the gas through the water in the bottle D. In the cork at E, another tube allows the gas to pass into the balloon; or two small casks may be used in place of bottles.—Another method for producing the hydrogen gas is represented in fig. 18. ABC is a vessel of clay or iron, into which the materials yielding the gas are introduced, so as to occupy 4-5ths of its cavity. This vessel is subjected to the action of fire, if it contain coal; the gas passes through the tube CD, and also through the water in the tub H, into the inverted

*Balloon Gas Apparatus.*

#### Hydrogen Gas.

FIG. 17.

vessel EF, to the upper aperture of which the balloon G is tied to receive the gas. The fire should be at a considerable distance from the tub H, that the inflammable air, if any escape, may not explode and do mischief.

The old apparatus for filling an inflammable air balloon of the largest dimensions, is represented in fig. 19. A, A are two tubs, or gasometers, about three feet in diameter and nearly two-feet deep, inverted in larger tubs: at the bottom of each of the inverted tubs there is a hole, to which is adapted a tin tube, E, about seven inches in diameter, and seven or eight inches long. To these tubes the silken tubes of the balloon are tied. Each of the tubs, B, is surrounded by several strong casks, so regulated in number and capacity, as to be less than half full when the materials are equally distributed. In the top of each of these casks are two holes; and to one of the holes is adapted a tin tube, formed so as to pass over the edge of the tub B, and through the water, and to terminate with its aperture under the inverted tub A. The other hole, which serves for supplying the cask with materials, is stopped with a wooden plug. These tin tubes may be about three inches and a half diameter, and the other holes may be smaller. Two masts, with a rope, &c. are used for this machine, although they are not absolutely necessary; because the balloon, by means of a narrow scaffold, or other contrivance, may be elevated five or six feet above the level of the tubs A, A. When the balloon is to be filled, the net is put over it, and suspended as exhibited in C D F: and having expelled all the common air from it, its silk tubes are fastened round the tin tubes EE, and the materials in the casks are properly proportioned, the iron being first put in, then the water, and lastly the vitriolic acid. The balloon will soon be inflated by the inflammable air, and support itself without the aid of the rope GH. As the filling advances, the net is adjusted round it; the cords proceeding from the net are fastened to the hoop MN; the boat, IK, is suspended from the hoop MN, and every thing necessary for the voyage is deposited in it. When the balloon is a little more than three-quarters full, the silken tubes are separated from the tin tubes, and their extremities

being tied, they are placed in the boat. Finally, when the aeronauts are seated in the boat, the lateral ropes are slipped

Fig. 19.

off, and the machine ascends in the air, as in fig. 20. In order

FIG. 20.

to produce such a bulk of inflammable air as is necessary for a balloon of 30 feet in diameter, whose capacity is 14,137 cubic feet, there will be required about 3900 lbs of iron turnings. 3900 lbs of vitriolic acid, and 19,500 lbs of water, with which the balloon will not be above three-quarters full. The usual way now of filling a balloon with the carbonated, or carburetted, hydrogen gas, the same as the streets are lighted with, is to introduce it through any service pipe into the balloon, from any of the station pipes connected with the gasometer of any of the great gas manufactories in the neighbourhood of the aeronaut's ascent. Of course, all the apparatus of casks, &c. is done away with: but some degree of caution is requisite in managing the machine when afloat, and highly elevated; for should the larger valve in the top of the balloon be opened by the aeronaut in place of the smaller one, as unfortunately was done by the late Mr. Harris, too much gas may escape, and the vehicle be precipitated with

great velocity perpendicularly to the ground. Mr. Harris ascended from the City-Road, London, May 25, 1824, and in the neighbourhood of Croydon, Surrey, his balloon came rapidly to the ground, from his having pulled the cord of the larger in place of that of the smaller valve, to descend; and he was killed on the spot. His fair companion, a young lady, was very much injured by the fall.

**Construction of Balloons.**—The balloon itself is composed of gores of silk, fig. 21, covered with caoutchouc varnish, and probably 30 feet diameter. A net is spread over the whole hemispherical surface. To this a car or boat is suspended by ropes, so as to hang a few feet below the balloon; and in order to prevent the bursting of the machine, a valve is placed in it; sometimes two valves, one within the other, to allow the gas to escape when the aeronaut wishes to descend. The basket may be 8 feet long, 4 wide, and 3½ deep, of wickerwork; and the weight of the whole apparatus about 5½ cwt. including the voyager.—The conduct of balloons has been attempted to be placed under the power of the aeronaut, by means of wings or oars, fig. 22. Blanchard used this sort of wing of silk, stretched upon cane, and used edge-wise in the direction in which the balloon is driven.—Lunardi tried

shutters of silk, or rather valves, *a, b, c*, as fig. 23, to open on one side only, and be moved on the flat side in the direction in which the machine is impelled. But the aeronaut has little or no power over the machine when it is suspended in the air.—Baldwin, who ascended from Chester in 1785, compares the sensation of ascending to that of a strong pressure from the bottom of the car upwards against the soles of the feet. At the distance of one mile he fancied he had gone seven. The river Dee appeared red, the city diminutive, the town blue, and all reduced to one grand enchanting level; the clouds seemed a sea of fleecy cotton, the thunder-clouds like the dense smoke of cannon. The shadow of the balloon upon the white floor of clouds, was, at times, no bigger than an egg; at others, greatly increased, and surrounded with the most captivating iris or rainbow. At four miles high the air was warmer than on earth: the sun was hottest when the balloon was stationary.—Mr. Sadler, who, in the summer of 1824, ascended from Liverpool, erected an extensive apparatus for filling his balloon with gas, of a quality sufficiently buoyant to bear up more than the usual weight. The apparatus consisted of a large boiler, heated by two furnaces, and a number of cylindrical retorts, communicating by pipes, leading to a general conduit;—the whole being on the principle of simply decomposing water by means of heated iron filings, borings, and turnings. The balloon was 34 feet diameter, by 42 feet high, covered with 560 square yards of silk, containing 28,000 cubic feet of gas, which would raise 12 cwt. from the earth. The balloon arose at 3 p. m. and took a S.E. course towards Chester, near which place it descended between 5 and 6 p. m. The mountains of Wales were visible to Mr. Sadler and his companion; but the sea was hid by clouds.—On the 14th of June, 1824, Messrs. Green and Sparrow ascended from the gas-works of Oxford, about 3 p. m. The balloon travelled 23 miles towards Henley, where it was brought down. Mr. Sparrow was thrown out of the car, when the balloon came first in contact with the earth, but received no injury.—A Mr. Graham and his wife, about the same period, ascended from London, and descended about 14 miles from Brighton, after a voyage of 1 hour and 20 minutes, without experiencing any accident.—Since the above was written, poor Sadler was killed in one of his enterprising voyages.

**ÆSCULUS**, in Botany, horse-chestnut, which, as a powder, excites sneezing: infused, it is good for complaints in the

head and eyes. The bark of the tree is considered a good febrifuge.

**ÆSTIVAL**, belonging to summer, as the æstival solstice, sign, &c.

**ÆTHER**, in Chemistry, a light, volatile, and very inflammable liquid, produced by distillation of acids with spirits of wine. The too frequent use of æther is very injurious to the nervous system; yet many people take it freely.

**ÆTHUSA**, fool's parsley, possesses poisonous qualities.

**AETITES**, eagle stones, flinty crustated pebbles, of a yellow colour, hollow within, and containing a nucleus, which rattles if the stone be shaken.

**AFFERERS**, in Law, persons appointed in courts leet, courts baron, &c. to settle the fines upon those who have been guilty of faults arbitrarily punishable.

**AFFETTUOSO**, or *Con Affetto*, in Music, whatever is played in a moving style.

**AFFIDAVIT**, in Law, an oath in writing, sworn before a competent authority.

**AFFINITY**, in Chemistry, is that power which tends continually to bring particles of substances together which are disunited, and which retains in connection, with more or less force, those already in a state of combination. When olive oil and water are shaken together, they refuse to act upon each other, and separate according to the order of their densities, the oil swimming above the water. Oil and water will not mix intimately; they will not combine; and are said to have no chemical attraction or affinity for each other. But if oil and soap lees, or solution of potash in water, be mixed, the oil and the solution blend together, and a species of soap will be formed, which may be procured as a soft solid substance by evaporating a part of the water. This is an instance of combination; and solution of potash and oil are said to attract each other chemically, or to have an affinity for each other. A spoonful of salt, thrown into a vessel of water, diffuses itself through the whole of the fluid, and the salt is combined with the water; the water and the salt have an affinity for each other, and cannot be separated by any mechanical means: but if another substance be introduced, to which water has a greater affinity than it has to the salt, it will quit the salt, to unite to this third substance. If alcohol be the third body, the water will leave the salt to join the spirit; and the salt, by its superior gravity, will be precipitated in the vessel. Alcohol will dissolve camphor, and the fluid be perfectly clear, which is another instance of chemical combination; the two substances have a strong affinity for each other: but the spirit has a still stronger affinity for water than for the camphor; and if a little of that fluid be added to the solution, the camphor will fall down in flakes, that is, in a solid form. Different bodies unite with different degrees of force; and hence, one body is capable of separating others, from certain combinations: and in consequence of the same circumstance, mutual decompositions of different compounds take place. This has been called *double affinity*, or *complex chemical attraction*. Thus, if an aqueous neutral solution of lime and nitric acid, and a like solution of magnesia and sulphuric acid, be mixed together, the lime will quit the nitric acid, to unite to the sulphuric acid, and the magnesia will leave the sulphuric acid, to combine with the nitric acid. The combination of nitric acid and magnesia will remain in solution; but the compound of lime and sulphuric acid, being only slightly soluble in water, will, for the most part, be precipitated in the form of a white powder. Every substance has its peculiar affinities to the various other substances presented to it. If all bodies had the same degree of affinity with each other, no change could take place amongst them; and we should not be able to displace any principle by presenting one body to another. It is in consequence of this difference in the affinities, that all chemical decompositions are affected; and all the operations of nature and art are founded upon it. Hence arises the terms, *simple affinity*, *double affinity*, &c. Two principles united, and then separated by means of a third, afford an example of simple affinity: it consists in displacing one principle by the addition of a third. The body disengaged is called the *precipitate*; the substance used to separate the compound, is called the *precipitant*. An alkali precipitates metals from their solutions. Sometimes the law

# AFRICA.

30° Longitude West 20 from Greenwich 40 50 60 70 Longitude East 80 from Greenwich 70

compound itself is precipitated, as when the vitriolic acid is poured on a solution of the muriate of lime. At other times, the disengaged body, and the new compound, are precipitated together, as when Epsom salt is dissolved in water, and precipitated by means of lime water. The compound of two principles cannot be destroyed either by a third or fourth body separately applied: but if these two bodies be united, and then brought into contact with the same compound, a decomposition will take place. This phenomenon constitutes *double affinity*, as when *vitriolated tartar* is decomposed by nitric acid combined with lime.

**AFFIRMATION**, in Law, an indulgence allowed to the people denominated Quakers; giving them the privilege of deposing upon their mere word of honour, what other sects must attest upon oath. If the Quaker in this perjures himself, he suffers accordingly.

**AFFRONTÉE**, in Heraldry, an appellation given to animals fronting one another in an escutcheon.

**AFRICA**, [*Map*,] one of the four great divisions of the earth, extending from north to south about 70°, or 4200 geographical miles. This vast continent occupies about 69° of longitude, or 4140 geographical miles. It is divided into Abyssinia, Egypt, the Mahometan States in the North, the Western Coast, the Cape of Good Hope, and the countries on the Eastern shores. The islands are, Madagascar, Bourbon, Mauritius, Kerguelen's Land, St. Helena, the islands of Cape Verd, the Canaries, and Madeira. The ruling religion is Mahometanism. The climate in the north is hot, in the south temperate. We know of no navigable rivers and lakes that can diffuse commerce from the shores to the centre of Africa. The chief rivers are the Nile, the Niger, the Senegal, the Zahir of Congo, and the Zambezi of Mocaranga. The mountains are those of Atlas, Abyssinia, and the Cape. And the great desert of Zaara stretches from the shores of Africa to the confines of Egypt, in length 2500 geographical miles, by a breadth of 720; and though interspersed with fertile spots, it is a vast ocean of sand, that defies every exertion of human industry.—[N.B. The geographical portion of this Dictionary is from one of the Editor's own works—the GRAMMAR OF GEOGRAPHY.]

Abyssinia, is bounded on the north and west by the mountains and forests of Kordofan and Sennaar; on the south, deserts and mountains separate it from Gingiro and Alaba, and the Red Sea skirts its eastern margin. It is divided into the provinces of Tigri, Gojam, Dembea, and Gondar, the capital. The religion is the Christian; the population may amount to three millions; and the government is absolute and hereditary monarchy. The climate is greatly diversified; for from April to September there are heavy rains, and though the six following months be dry, the nights are cold. No country can match Abyssinia in mountains and detached precipitous rocks. The African Alps are crowned with eternal snow, and from those of Kumri, issue the unexplored sources of the Nile. The chief lake is that of Tzana, called also Dembea, and lakes Zawaja and Haik. The horses of Abyssinia are small, but spirited; cattle and buffaloes are numerous; the elephant, the rhinoceros, the lion, the panther, the camelopardalis, are met with; hyænas infest Gondar at night; wild boars, gazelles or antelopes, and monkeys, swarm in the woods; the lakes and rivers abound in hippopotami and crocodiles.

Egypt, celebrated from all antiquity, is about 500 miles long, and nearly 250 broad. The entire country is a narrow vale, bisected by the Nile, and hemmed in by parallel ridges of mountains. The prevailing religion is Mahometanism, but there are many Christians, who have their priests and monasteries. The population is about two millions and a half. The government is in the hands of a viceroy of the Ottoman power; though, in Cairo, a powerful aristocracy directs the affairs of domestic policy. The people are in general filthy; the Copts, or original Christian inhabitants, are the men of business. The climate is peculiar, rain being uncommon, the heat extreme, enforcing an abstemious diet; the soil rich, agriculture of the simplest kind, the inundations of the Nile rendering vegetation luxuriant without much manual labour. The chief city is Grand Cairo, a dirty place, filled with 300,000 souls, pent up in narrow streets; Alexandria, Rosetta, and Damietta. Egypt, once the focus of oriental trade, and the

granary of Rome, still exports vast quantities of wheat, rice, and flax, and many black slaves; and from Tunis and Tripoli it receives oil, red caps, and fine flannel; from Syria, cotton, silk, soap, and tobacco; from Constantinople, white slaves, Circassians or Georgians, the males being the far-famed but ill-used Mamelukes. The chief river is the Nile, about one quarter of a mile broad, and twelve feet deep, of muddy water, but abundant in a species of salmon, eels, and crocodiles. The chief lakes are those of Menzala, Berelos, and Elko, in the north; Kerun in the west, and the Natron lakes, producing mineral alkali. The mountains lie chiefly between the Nile and the Red Sea. The pyramids are constructed of free-stone, like that used at Bath; and the ancient obelisks were dug out of quarries of red granite near Syene. The lotus or water lily decorates the Nile; the cypress overshadows the tombs of the dead; the sycamore flourishes with vigour even on the sandy frontiers of the desert; and the papyrus, sacred to literature, is found in the marshes of the Delta.

Nubia, or Ethiopia, 600 miles in length, and 500 in breadth, is an extensive tract between Egypt and Abyssinia. Its states are, Dongola in the north, and Senaar in the south. Nubia is a miserable country, and its people deceitful and ferocious.

The Mahometan States in the North, are, Tripoli, Tunis, Algiers, and Morocco, extending from Cades to the confines of Egypt. Tripoli is governed by a Bey, subject to the Porte or Sultan. The town is situate in a low spot, and is in a state of rapid decay. Tunis, the central region of northern Africa, was once the seat of the Carthaginian power. The ruins of Carthage are not far from Tunis the capital, a town about three miles in circumference, and containing 50,000 souls, the most polite and civilized among the Mahometans of Africa. Lions, panthers, hyænas, and other ferocious animals, are found here. Algiers is governed by a Dey or Pasha, who exacts tribute from the maritime states of Christendom; and whose country is a nest of robbers. The kingdom of Algiers comprises the Numidia, and part of the Mauritania, of the ancients; and the productions are wool, lead, oil, leather. There are many salt springs and rivers in the kingdom of Algiers, and there is one salt hill near the lake called Manks. The empire of Morocco, which includes also the kingdom of Fez, is peopled by civilized Moors, and wandering, but hospitable Arabs; but the Brebers, from whom Barbary takes its name, are fierce and obstinate descendants of the aboriginal inhabitants. The universal food consists of bits of paste cooked by the steam of boiled meat and vegetables, sewed up in an earthen dish, with butter and spices, and eaten alike by the peasant and the monarch. The chief sea-port is Tetuan. Morocco is the capital. But on the south of these Mahometan states, there are the countries of Drah, Sijelmissa, and the Land of Dates.

The Western Coast, is peopled by the Jalofs and Foulahs, on the banks of the Senegal and Gambia. Guinea is divided into the grain, the ivory, and the gold coast. Benin and Calabar, Congo and Angola, come next in order. The sovereign of Benin is said to be able to bring into the field 100,000 warriors. Laonga, on the north of Congo, possesses an industrious population, expert in weaving, smith's work, and the manufacture of canvass, caps, and beads. The Congoese have the negro colour, without the features; and these people practise the strange custom of opening the graves annually, to decorate the bones of the dead. These countries are well watered, and the usual tropical plants abound; rice, yams, gourds, potatoes, and melons, are the chief food of the inhabitants.

The Colony of the Cape of Good Hope. The territory of this colony is about 550 miles in length, and 233 in breadth, comprising a population of about 20,000 souls. The country is more fertile towards the east than on the western coast; and the chief roadsteads are False Bay on the south, and Table Bay on the north, which opens to Cape Town. The botany of southern Africa is peculiarly rich and magnificent, as is proved by the beautiful plants from thence, which decorate our British green-houses. And wolves, hyænas, antelopes, eagles, vultures, kites, crows, turtle doves, lions, and hippopotami, rank in the natural history of the Cape of Good Hope.

The Eastern Coast, includes the country of the Kaffres, or Koussis, and the Tambookies. The coast of Natal is followed by the Bay of Delagoa. Opposite to Madagascar are

Sabia, Sofala, Mocaranga. Then the coasts of Mozambique and Zanguebar; and the desert and obscure coasts of Ajan and Adel, complete the circuit of Africa. The country around the Bay of Delagoa abounds in cattle and poultry, and the fish are numerous and excellent; Deer Island affording abundance of turtle. The natives are Kaffres, that is, Pagans, of a bright black colour, tall and stout, good humoured and harmless. Mocaranga is inhabited by a civilized people, who are nevertheless superstitiously afraid of magical charms. The king is guarded by females. The spade, the emblem of agriculture, is worn by the king on days of ceremony, in place of a sword. An officer is sent annually to each province, and, in token of his fidelity, leaves his children as hostages at court. The people of the province, on the officer's appearance, extinguish their fires, but again light them from the officer's torch, in token of their loyalty. On the coasts of Ajan and Zanguebar there are considerable numbers of Moors: Mozambique is subject to the Portuguese; Zanguebar abounds in elephants. Of the other states little is known. Madagascar, 840 miles long, and 220 broad, abounds in grand and picturesque scenery, strikingly diversified with precipices, cataracts, and immense forests. The chiefs of tribes in this island are distinguished from their clan by *red caps*; the villages are fortified places, constructed on eminences; the magicians have an amazing sway over the more ignorant natives; and the most honourable trade is that of a butcher.—The islands of Pemba, Zanzibar, and Monsia, are opposite to the coast of Madagascar; and the isles of Mahé and Almiranti, are considerably to the east. The isles of Comoro are Angazzia, Anzoan, &c. governed by Mahometan chiefs, tributary to the Portuguese; and the domestic animals are, in general, like the European. The islands of Mauritius, or France and Bourbon, now in the possession of Great Britain, are to the east of Madagascar. These islands produce yearly two crops of wheat and Indian corn, and Bourbon is celebrated for its sugar canes, cattle, bread-fruit, nutmeg and cinnamon trees. Kerguelen's Land, or the *Island of Desolation*, situate in the centre of the great Southern Ocean, is noted chiefly as the resort of ships on the seal fishery; for its wildness and sterility set industry at naught. St. Helena has only one harbour, and that is difficult of access. This island is the regular resort of the East India Company's ships, and was lately remarkable as the residence of Buonaparte. The island of Ascension has an excellent harbour, and abounds in turtle and sea-fowl; but the country is mountainous, and the soil barren. The isles of St. Matthew, Annabon, St. Thomas, Prince's Isle, and Fernando-Po, are near the African shore.

The Interior Parts of Africa.—Darfur, a kingdom in the interior of Africa, has a capital called Cobbe, and the inhabitants are almost all merchants and foreigners. The flocks of sheep and of goats here are numerous; cows and camels abound; lions, leopards, hyænas, wolves, jackals, wild buffaloes, elephants, rhinoceroses, antelopes, and ostriches, are plentiful. Copper and iron are met with in vast mines; tamarinds and fruit-trees are common. The government is hereditary monarchy; but the Darfurs are a dissolute, wanton people, amounting to about two millions of souls. The Moorish kingdom of Ludamar, that of Beeroo, Tombuctoo, Kaarta, and Bambarra, have been described by that enterprising and ingenious traveller, Mungo Park. Also the kingdoms of Houssa, Kassina, Gotto, Baédoo, and Maniana; Kulla, Bergoo, Fur, Bornou, and Ashantee, by other travellers.

AGALLOCHUM, a fragrant medicinal wood, brought from the East Indies.

AGAPE, a love-feast, or feast of charity, as practised by the first Christians, who had all things common. This feast has been revived by the Wesleyan Methodists, and by some sects of Particular Anabaptists.

AGARIC EARTH, found in fissures of rocks, roofs of caverns, &c. and sometimes used as an astringent in fluxes, hæmorrhages, &c.

AGARICUS, the botanical name of the mushroom.

AGATE, a precious stone, either yellow or green, lead-coloured, or sanguine. Agates may be obtained artificially with solution of silver in spirit of nitre, and afterwards exposing the part to the sun. The most remarkable agate was that

of Pyrrhus, in which was depicted the nine muses, and Apollo playing on a harp. There is one on the continent, in Austria, we believe, fashioned into a cup nearly an ell in diameter.

AGAVE, the American aloe.

AGE, in ancient Chronology, the space of 30 years; thus, Nestor lived 3 ages, or 90 years; but sometimes it denotes 100 years. In Law, a certain period of life, as 21 years, when a person is said to be *come of age*.

AGER, a Roman acre of land.

AGERATUM, bastard hemp agrimony.

AGGER, in ancient warfare, a fortified work to defend a camp or position; in modern tactics, the lines of approach, or trenches, correspond with the *aggere* of the ancients.

AGGREGATE, the sum of several things added; and *Aggregation* is the mass, as a heap of sand, of ruins, &c.

AGIO, in Commerce, the difference between bank stock and current coin, in Holland and Venice.

AGMEN, a Roman army in march, which consisted of three *agmina*, or divisions; van, main body, and rear.

AGNUS CASTUS, a plant, upon which the Athenian ladies, who made a profession of chastity, used to lie during the feasts of Ceres.

AGRICULTURAL INSTRUMENTS, are the plough, harrow, roller, &c. &c.

1. The Plough, fig. 24, is a machine drawn by horses, and guided by a husbandman, for turning up the soil, and preparing it to receive the corn, &c. The chief parts of this instrument are, the *coulter*, W E F; the *sock*, C, fixed on the base C M: M is the *heel*. The sock and coulter are of iron. A L is the *sheath*; P Q the *stilt*; R L K the *beam*; H the coulter stay. There are

The Plough.

ploughs of a different construction to this; but the most remarkable are, the

2. *Four-coultered Plough*, fig. 25, moving on two wheels, of which the left-hand one is 20, and the right-hand one 24 inches diameter; separated 2 feet 6 inches from each other. The plough beam is 10 feet long.

Fig. 25.

3. The *Paring Plough*, represented in fig. 26, will be readily understood from the figure: its use is to pare off the rough stubble, or surface of the ground, in order to its being burnt. E is the paring plate; the beam is seven feet long.

Fig. 26.

5. The *Chain Plough*, fig. 27, so termed because drawn by a chain, fixed to the back part of the beam immediately before the coulter, has two advantages; first, by means of a muzzle, it makes the plough go deep or shallow; and, next, it stresses the beam less than if fixed to the point, and therefore a slenderer beam is sufficient. This plough, of a smaller size than ordinary, can be drawn by a single horse, and is the

most proper for horse-hoeing, making dung-furrows, drills, &c. &c.

Fig. 27.

5. *The Brake*, fig. 28, a large weighty harrow, is used to reduce stubborn soils. It consists of four pieces of oak,  $6\frac{1}{2}$  feet long, 5 inches square; with teeth 17 inches long, bending forward like a coulter.

6. *The Common Harrow* is, in figure, like the brake, but much lighter made: the teeth may be wood or iron, from ten to twelve inches asunder.

7. *The Chain and Screw Harrow*, fig. 29, designed to bend with the ridges, either from their crowns, or from their furrows, even if the sides of the ridges be 18 feet broad. This harrow may be differently made; as by joining two common harrows by a chain, so that they shall bend to the curvature of the

F 28.

Fig. 29.

ridges. In the same way, a grass harrow may be framed when the land is not laid down in meadow form, perfectly level.

8. *The Roller*, made of stone, wood, or cast iron, should weigh 200 stone, without shafts; but constructed of cast iron, it is sometimes a ton and a half weight. A piece of beech wood, surrounded with three rows of felloes, lined with planks equally long, and the whole clasped together with iron rings  $3\frac{1}{2}$  feet diameter, makes a good agricultural roller.

9. *The Patent Universal Sowing Machine*, may be made to be worked by hand, drawn by a horse, or fixed to a plough. Simple in its construction, and therefore not readily put out of order, having but one movement to direct the whole, it requires

Fig. 30.

no skill in working; and will sow wheat, barley, oats, rye, clover, turnip seed, &c. with an accuracy hitherto unknown. Fig. 30 represents the machine fixed to a double-furrow creasing plough, and prepared for drilling.

10. *The Scythe*, fig. 31, is a well known instrument in husbandry; and the *Silesian Scythe*, which we will here describe, differs little from that commonly used in mowing grass, except that the blade is rather smaller; to it, four teeth of wood are attached parallel to the blade, fixed and secured in a proper

Fig. 31.  
*Silesian  
Scythe.*

manner, and designed to keep the corn together after it is cut; so that, instead of its falling in a confused state, the reaper can lay it down in a regular and compact manner. The handle, *a b*, is 4 feet 3 inches long; the blade, *b c*, about 2 feet; the upright, *b d*, 1 foot 10 inches.

11. In the *Collector Scythe*, fig. 32, the handle, *a*, is 4 feet 1 inch; the blade, *b*, 2 feet 8 inches; the upright, 12 inches: the collector is of cloth, and may be added to the common scythe

Fig. 32.  
*The  
Collector.*

with a piece of sheet iron at the tip of the blade. The collector is fixed on by stout iron wires, *c*, and will be well enough understood from our engraving. This instrument is preferable to the above, though both are excellent.

12. *The Irrigating Machine*, is an instrument designed to raise water to a great height for the irrigation of land, in such situations as have the advantage of a small fall: it depends on the principle of Hero's fountain, and it may properly be inserted here. See Hero's fountain, article *JET D'EAU*. Fig. 33, *a, b*, is the stream of water: *b, c, c*, represents the waterfall, supposed to be 10 feet: *d, e*, are two leaden or cast iron vessels, containing about 4 or 6 gallons of water, and *f, g, h, i, k, l*, are leaden or iron vessels holding about two quarts each: *o, p*, are two cocks, each of which passes through two pipes, opening the one, and closing the other: *g, r*, is a water balance, which works on its centre *s*, and by which the cocks *o* and *p* are alternately turned: *t, u*, and *v, x*, are air-pipes made of lead, both  $1\frac{1}{4}$  inch diameter internally; and *y, z; y, z; y, z*; are water-pipes, each 1 inch diameter. The pipe *b, e, c*, is always full from the stream *a, b*; the small cisterns, *g, i, l*, and the large one, *d*, are supposed to have been previously filled with water. The fluid may then be admitted by turning the cock *o*, through

the pipe *c, e*, into the larger cistern *e*. The water will then press the air confined in the cistern *e*, up the air-pipe *w, x*, and force the fluid out of the cisterns *g, i, l*, into those marked *h, k, &c.* At the same time, by opening B, the water and condensed air, which previously existed in the large cistern *d*, and in the less ones *f, h, k*, will be discharged at B. In a short time, the water balance, *q, r, s*, will turn the cocks *o, p*, and push out the water, opening, during this operation, the opposite ones; the cisterns *f, h, k*, are emptied in their turns by the condensed air from the cistern *d*, as the water progressively enters the latter pipe *b, c*.—These, and many more, which our limits compel us to omit, are the most useful machines used in agriculture. Carts, waggons, threshing mills, &c. we shall describe in their proper places, agreeably to the alphabetical arrangement of this Dictionary.

**AGRIMONIA**, Agrimony: *hemp* and *water-hemp* agrimony, occur in botany. Common agrimony is aperient and detergent; good in scorbutic disorders, and debility of the intestines. Digested in whey, it makes a good and useful diet-drink for the spring.

**AGROSTEMMA**, wild lichens, or campions.

**AGROSTIS**, bent-grass. *Agrostographia*, the history or description of grasses.

**AGUE**, a periodical fever, which, according to the different returns of the feverish paroxysms, is denominated tertian, quartan, and quotidian.

**AHEAD**, a sea term, expresses the situation of any object in advance of the ship; and is used in opposition to *astern*, which denotes the position of any object behind the ship.

**AHULL**, the situation of a ship when all her sails are furled, on account of the violence of the wind, and when, having lashed her helm on the lee side, she lies nearly with her side to the wind and sea, her head being somewhat inclined in the direction of the wind.

**AIDS**, in the Manege, cherishings used to avoid the necessary corrections. The *inner aids* are the inner heel, leg, rein, &c.; the *outer aids*, the outer heel, leg, rein, &c.

**AIGHENDALE**, in Lancashire, a liquid measure of 7 quarts.

**AIGUISCE**, in Heraldry, a cross with its four ends sharpened into obtuse angles.

**AIR**, a thin, elastic, transparent fluid; ponderous, compressible, and dilatable.

**AIR**, in Music, melody in general, a tune.

**AIR-Pipes**, an invention due to Mr. Sutton, a brewer, of London; being intended for clearing the holds of ships, and

other close places, of their foul air. The principle upon which this contrivance is founded, is well known; being no other than the rarefying power of heat, which by causing a diminution in the density of the air in one place, allows that which is in contact with it to rush in, and to be succeeded by a constant supply from remoter parts, till the air becomes every where equally elastic. If, therefore, one end of a long tube be placed in the hold, or place to be purified, while the other end of the tube be sufficiently heated, the foul air will be constantly drawn up, and supplied by fresh air from above.

**AIR-Pump**, a popular pneumatic machine, that draws out or exhausts the air in a proper vessel. The construction of this machine, and its principle of action, may be thus explained, fig. 34:—Let B represent a section, (the section of a perfectly uniform metallic barrel or pipe,) communicating with the glass receiver A, by means of the inferior tube *t, t*; let P be a piston, attached to the rod R, and fitting the barrel air-tight; *v* and *v*, are two valves opening upwards, one in the piston, the other in the end of the tube *t, t*. CD supports the receiver, which is placed on wet leather collars. When the piston-rod is pushed down, the air in the barrel is compressed, the lower valve shut, but the valve of the piston opens, and allows the air in the barrel to rush out. When the piston is drawn up, its valve is shut by the external atmosphere; but the air in the receiver pushing up the valve *v* of the tube, rushes into the barrel, which is again filled with air as much rarer than before, as the contents of both barrel and receiver exceed that of the receiver alone. Every stroke diminishes the density of the confined air in a constant proportion, namely, as much as the whole content exceeds that of the cylinder or barrel; and consequently, the sum of as many diminutions as there are strokes of the piston, will shew the whole diminution by all the strokes. So, if the capacity of the barrel be equal to that of the receiver, in which the communication-pipe is always to be included, then, the barrel being half the sum of the whole content, half the air will be drawn out at one stroke; and consequently, the remaining half, being dilated through the whole or first capacity, will be of only half the density of the first; in like manner, after the second stroke, the density of the remaining contents will be only half of that after the first stroke, that is, only  $\frac{1}{4}$  of the original density: continuing this operation, it follows that the density of the remaining air will be  $\frac{1}{8}$  after 3 strokes of the piston,  $\frac{1}{16}$  after 4 strokes,  $\frac{1}{32}$  after 5 strokes, and so on, according to the powers of the ratio  $\frac{1}{2}$ ; that is, such power of the ratio as is denoted by the number of the strokes. In like manner, if the barrel be  $\frac{1}{3}$  of the whole contents, that is, the receiver double of the barrel, or  $\frac{2}{3}$  of the whole contents; then the ratio of diminution of density being  $\frac{2}{3}$ , the density of the contents, after any number of strokes of the piston, will be denoted by such power of  $\frac{2}{3}$ , whose exponent is that number; namely, the density will be  $\frac{2}{3}$  after one stroke,  $(\frac{2}{3})^2$  or  $\frac{4}{9}$  after two strokes,  $(\frac{2}{3})^3$  or  $\frac{8}{27}$  after three strokes, and in general it will be  $(\frac{2}{3})^n$  after *n* strokes: the original density of the air being 1.

**The Common Air-Pump**, fig. 35, is both portable and convenient. E, F, G, H, is a square table of wood; A, A, two strong barrels of brass firmly fixed by the head bar T, T, and the pillars N, N. These barrels communicate with two tubes, as shewn in diagram 34, each having its valve opening upwards, as have also the pistons their valves. In this machine the pistons are worked by a cog-wheel fixed in the bar T T, and turned by the handle B. The teeth of the wheel work in the piston racks C, C. P Q, a circular brass plate to hold the receiver, has a hole in its centre that communicates with the piston tubes. In the piece D, at V there is a screw which closes the orifice of one pipe for the purpose of admitting the external air when required. L M is the glass receiver, out of which the air is to be exhausted, when placed on the plate P Q, which is previously covered with a wet sheep-skin, or smeared with wax, to prevent the air from insinuating under the edge of the glass. When the handle B is turned,

one of the pistons is raised, and the other depressed; consequently a void space is left between the raised piston and the lower valve in the correspondent barrel: the air contained in the receiver L M communicating with the barrel by the orifice K, immediately raises the lower valve by its spring, and expands into the void space, and thus a part of the air in the receiver is extracted. The handle then, being turned the contrary way, raises the other piston, and performs the same act in its correspond-

ent barrel: while, in the mean time, the first-mentioned piston being depressed, the air by its spring closes the lower valve, and, raising the valve in the piston, makes its escape. The motion of the handle being again reversed, the first barrel again exhausts, while the second discharges the air in its turn: and thus, during the time the pump is worked, one barrel exhausts the air from the receiver, while the other discharges it through the valve in its piston. Hence it is evident, that the vacuum in the receiver of this air-pump (and the same may be said of all others) can never be perfect; that is, the air can never be entirely exhausted: for it is the elasticity of the air in the receiver that raises the valve, and forces air into the barrel; and the barrel at each exsuction can only take away a certain part of the remaining air, which is in proportion to the quantity before the stroke, as the capacity of the barrel to the sum of the capacities of the barrel, receiver, and communicating pipe. And we have shewn the ratio of exhaustion, going on in geometrical progression, until the elasticity of the included air is too feeble to push up the valve of the piston, when the receiver is said to be exhausted.—The specific gravity of air may be very accurately ascertained by means of this machine, and the method is as follows: To the neck of a glass bottle, made in the form of a Florence flask, adapt a cap and valve opening outwards, screw it on the pump, and exhaust it to a known degree, which will be shewn by the gauge attached to the pump for that purpose; then from the weight of the bottle before and after exhaustion, we have the weight of the exhausted air; and from the ratio of the height of the mercury in the gauge to the standard altitude, we know the proportion which the exhausted part bears to the whole air originally in the vessel, whose weight is therefore known. Subtracting this weight from the weight of the vessel when full of air, there will remain the weight of the vessel itself: fill it with water, and weigh it, and subtract the weight of the vessel from this weight; the remainder is the weight of a bulk of the same magnitude with the air which fills the vessel, and whose weight was also previously ascertained. Following this method, it has been found by a mean of several experiments, that the specific gravity of air is to that of water as 1.222 to 1000, very nearly, when the barometer stands at 30 inches, and in the mean temperature of 55° of Fahrenheit's thermometer. This agrees with the result already given.—Some of the principal effects and pheno-

mena of the air-pump are the following:—That, in the exhausted receiver, heavy and light bodies fall equally swift; so, a piece of metal and a feather fall from the top of a tall receiver to the bottom exactly together: That most animals die in a minute or two: but, however, that vipers and frogs, though they swell much, live an hour or two; and after being seemingly quite dead, come to life again in the open air: That snails survive about ten hours; efts, or slow-worms, two or three days; and leeches five or six: That oysters live for 24 hours: That the heart of an eel taken out of the body, continues to beat for a good part of an hour, and that more briskly than in the air: That warm blood, milk, gall, &c. undergo a considerable intumescence and ebullition: That a mouse, or other animal, may be brought, by degrees, to survive longer in a rarefied air, than it does naturally: That air may retain its usual pressure, after it is become unfit for respiration: That the eggs of silk-worms hatch in vacuo: That vegetation stops: That fire extinguishes, the flame of a candle usually going out in one minute, and live charcoal in about five minutes.

*Cuthbertson's Air-Pump*, is exhibited in fig. 36, with its two principal gauges screwed into their places; but these are seldom used, except when great delicacy is required; for in the common experiments one of them is removed, and a stop-screw put in its place: and when all the three gauges are used, the stop-screw B admits the air into the receiver. The dotted lines represent a transverse bar that keeps the barrels steady: N, N, are two slips of wood that keep this bar down: O, O, are screws that fix it.

Fig. 37 is a section of one of the barrels with all its internal parts, and figs. 38, 39, 40, and 41, are different parts of the piston, proportioned to the size of the barrel, and to one another.

In fig. 37, C D represents the barrel, F the collar of leathers, G a hollow cylindrical vessel to contain oil. R is also an oil-vessel to receive the oil which is drawn, along with the air, through the hole *aa*, when the piston is drawn upwards; and, when this is full, the oil is carried over with the air, along the tube T, into the oil-vessel G. *cc* is a wire which is driven

ment is inverted. In fig. 44 you have a full sight of Mendelssohn's air-pump, wherein A B, C D, are cylinders of glass, ground and polished inside. E and F, valves allowing the cylinders to communicate with the receiver O, through two very short

canals *ab*, *cd*, fig. 45, and the cock G. Two other valves that open into the atmosphere, are within the covers *i* and *k*, as may be seen in fig. 45, where *e* represents one of them. M N, the receiver plate. P Q barometer gauge. H K and I L, brass pillars that support the whole. R S V W, the usual rack-work, with a double winch *lm*. The whole instrument is fixed upon a mahogany table. R S, W V, support the racks and the diagonals, on which the pinion of the cog-wheel moves.—To shew how this pump acts, it will be sufficient to explain the action of one cylinder, because the other is in all parts like it. E is a conical metallic valve, from which a canal goes through the cock G up to the receiver, as is seen in fig. 45 and 46, where all the parts are marked with the same letters. E T is a steel rod going through a leather box in the piston U. The top of this rod is fixed to the valve E, and its bottom part slides in a small hole with an allowance of 0.1 inch up and downward, consequently the valve E can move no further. When the piston descends, it opens the valve by pushing the rod to the bottom of the hole. Then it slides down the rod E T, and the air from the receiver has access to the cylinder. When the piston returns, it lifts the rod E T, and shuts up the valve. Then the piston slides along the rod to the top of the cylinder, condensing the air above it, which, by the least condensation, opens a valve *e*, fig. 46, and escapes freely into the atmosphere. This last valve has neither spring nor additional weight to shut it, but shuts by its own weight, (about a quarter of an ounce,) as soon as the piston is arrived at the top of the cylinder. The cylinders are made of glass, and the pistons of tin, so well fitted as to be air-tight, without the interposition of any leathers. The friction of these two bodies is remarkably small; a sufficient proof that they will be durable. They possess the further advantage of being capable of standing for even six months; after which time they will serve without being cleaned or repaired, because they are not liable to be corroded by the oil which they contain, an inconvenience too general in brass cylinders. If the present pump should want cleaning, take off the top piece *gh*, by unscrewing the nuts H and I, when this piece, with all the apparatus upon it, will come off. Then each cylinder may be slid off from the piston, wiped and replaced, after having greased it inside with a little sweet oil; the top is then put in its place, and the two nuts H and I being screwed upon it, the instrument is ready. Neither racks nor pinion need to be taken out of their places,

Fig. 44.

Fig. 46.

the cylinders standing above them. The cock is constructed so, that, being in the situation represented in fig. 45, the communication is open between the cylinders, the receiver, and the barometer-gauge, and, by a quarter of a revolution, the cylinders are excluded, the receiver and gauge being still left in communication. A little stopper, ground into the cock, being open, air is admitted into the receiver, if it is required. The glass cylinders, the method of the valves opening, are new; the metallic pistons, without leathering, add to their durability, and lessen the labour of pumping. In short, the whole is vastly superior to the common pump.

AIR LAMP, a pneumatic machine, formed by the combination of hydrogen gas and electricity, which by turning a stop-cock, produces a flame that may be regulated at pleasure.

AIR GUN, fig. 47, a pneumatic instrument, which will drive a bullet with great violence by means of condensed air forced into an iron ball, B, by means of a condenser. The operation depends upon the elastic power of air, which increases in proportion to the degree of condensation imposed on it. Now the elastic power of fired gunpowder being equal to the pressure of 1000 atmospheres, or 1000 times greater than that of common air, it follows, that in order to produce the same effect with an air-gun as with a firelock, the air must be compressed into one-thousandth part of its natural bulk; and for all inferior degrees of condensation, the effect will be proportionally diminished; and as the velocities with which equal balls are impelled, are directly as the square roots of the forces acting upon them, we shall be able always to estimate the effect previous to any explosion taking place.

Fig. 47.

The Condenser, fig. 48, forces the air into the ball B; at the end *a* is a male screw, on which the hollow ball B is screwed, in order to be filled with condensed air. You set your feet on the rod *hh*, take the handle *ii* into your hand, and pump the ball *b* full of air, which the screw *a* secures till you fasten the ball to the gun for use.

Fig. 48.

The Air-Dagger, fig. 49, is thus produced. A B C is a thin partition of a room down to the floor, with an apparatus for a good convex lens, H, turned outwards into the room nearly in a horizontal direction, so as to be viewed by a person standing at F. The large concave mirror D is supported at a proper angle, to reflect upwards through H the glass in the partition B, images of objects at E presented towards the mirror below. A strong light from a lamp L, being directed on the object, and no where else, than to the eye of the spectator F, in a darkened room; it is truly surprising and admirable to what effect the images are reflected up in the air at G. Exhibitions of spectres are formed on this principle of catoptrics.

AIRA, in Botany, hair-grass.  
AIRS, in the Manege, the artificial motions taught horses, as the demivolt, curvet, capriole.  
AIRY, or AERIE, the nest of a hawk or eagle. AIRY triplicity, the three signs, Gemini, Libra, Aquarius.  
AJUGA, in Botany, the bugle.  
AJUTAGE, a tube fitted to the mouth of the vessel through which the water of a fountain is played: and to the different variety of form and structure of *ajutages* may be ascribed the great difference in fountains.

Fig. 49.

ALÆ, the lobes of the liver: the cartilages of the nostril.

ALABASTER, a mineral, differing from marble in being combined with sulphuric acid.

ALARM, the firing of a gun, &c. to give notice of an enemy, &c. Clocks and watches sometimes have *Alarms*, or *Alarm*s.

ALARM *Bell*, that rung upon any sudden emergency: *Alarm* post, a rendezvous: *Alarm*, in Fencing, a challenge.

ALBA-FIRMA, rent paid in silver, and not in coin, which was called *black mail*.

ALBIRO, a star of the fourth magnitude, in the Constellation Cygnus.—ALBORO, a small red fish caught in the Mediterranean.—ALBUCA, bastard star of Bethlehem.—ALBUGO, a white spot on the cornea of the eye, that produces blindness.

ALBUMEN, the white of an egg; an animal or vegetable substance.

ALCE, the elk.—ALCEA, holly-hock.—ALCEDO, the kingfisher.

ALCHEMILLA, ladies' mantle; both the leaves and roots of which might be of use where mild astringents are required.

ALCHEMY, that branch of Chemistry which had for its principal objects, the transmutation of metals into gold; the panacea, or universal remedy; an alkahest, or universal menstruum; an universal ferment; and many other things equally ridiculous.—*Alchemy* took its rise among the Arabians, about the commencement of the fourth century. This delusive dream holding out a bait to avarice, soon attracted a host of followers. Intoxicated with the idea of boundless wealth, they occupied their time in searching for the philosopher's stone, and for a panacea or universal remedy, which should cure every disease, and confer the boon of immortality on the fortunate discoverer of the invaluable secret. Dioclesian, fearful that the visions of the alchemists might be realized, ordered all their books to be burnt. Roger Bacon the alchemist was excommunicated by the pope, and suffered ten years imprisonment for supposed dealing with the devil; and Paracelsus was thought to have an evil spirit in the pommel of his sword. The language of this prince of alchemists was a tissue of boasting and falsehood: he promised immortality in this world to his disciples, but his own death, in 1541, opened the eyes of his deluded followers, and blasted their sanguine hopes.

ALCOHOL, spirit of wine highly rectified: it is light and inflammable, and being highly antiseptic, is used to preserve animal substances. The spirit of wine of commerce is only an approximation to the state of alcohol, and it is found in the shops of every degree of strength above that of proof spirit, but divested of all colour. It is obtained merely by a redistillation of proof spirit;—but to free spirit of wine, as much as possible, from the water with which it is always more or less combined, and to bring it to the state of alcohol, the aid of other processes besides that of distillation are necessary. To obtain pure alcohol, Rouelles, a very able French chemist, recommends to draw off half the spirit in a water bath; to rectify this twice over, drawing off two-thirds each time; then to add water to this alcohol, which will turn it milky by separating the essential oil still remaining in it; afterwards to distil the spirit from the water, and rectify it by another distillation. Alcohol is not, however, in this state quite pure; it may yet be freed from a portion of water, by means of an alkaline salt. For this purpose, muriate of soda (common salt) may be advantageously employed, by first depriving it of its water of crystallization by heat, and adding it hot to the spirit. The subcarbonate of potash is, however, considered to be preferable. About a third part of the weight of the alcohol should be added to it in a glass vessel, be well shaken, and then allowed to subside. The salt will be found to have absorbed water from the alcohol, which being decanted, more of the salt is to be added, and the process continued until the salt falls dry at the bottom of the vessel. The alcohol must now be subjected to a final distillation in a water bath, to deprive it of the red tint obtained from the potash, as well as from the alkali held in solution. Dry muriate of lime will have the same effect of abstracting the water from the alcohol, as the alkali just mentioned. Alcohol being much lighter than water, its specific gravity is used as a test of its purity. Fourcroy considered it as rectified to the highest point when its specific gravity was 829, that

of water being 1000; and this is perhaps nearly as far as it can be carried by mere distillation: by the addition of alkali, it may be brought to 813, at 60 Fahrenheit. According to the London College, it should be 815. The uses of alcohol are various; it dissolves with great facility the resins and essential oils, also camphor, bitumen, and various other substances, which renders it of great service in pharmacy, in various other arts, and to the perfumers in particular. When diluted with an equal quantity of water, constituting what is called proof spirit, it is used for extracting tinctures from vegetable and other substances; the alcohol dissolving the resinous, and the water the gummy parts. From its giving a steady heat without smoke, when burned in a lamp, it is extensively employed for heating water on the tea-table; and in many chemical operations, it is found extremely useful. It is in common use in preserving anatomical preparations, and many subjects of natural history.

ALCOR, a star in the tail of the constellation of the Great Bear.

ALCORAN, the Mahometan's Bible. See KORAN.

ALCOVE, in Architecture, a recess, or part of a chamber separated by an estrade or partition of columns, and other corresponding ornaments, in which is placed a bed of state, and sometimes seats to entertain company.

ALDEBARAN, a star of the first magnitude in the constellation Taurus, called also the Bull's eye.

ALDER TREE. The alder grows in wet situations; its wood is useful in machinery, as cogs for mill-wheels, pumps, water pipes, &c.; the bark is useful in tanning, and in dyeing black, by the addition of copperas.

ALE, a fermented liquor, prepared either from wheat, or rye, or millet, or oats, or barley, or the berries of the quick bean. See BREWING.

ALE, *To Mull*. Put a pint of strong ale into a saucepan, with three or four cloves, nutmeg and sugar to your taste: set it over the fire, but whenever it boils, take it off, and let it cool. Beat the yolks of two eggs with a little cold ale; put this mixture to your warm ale, and pour the whole several times from your saucepan into a mug. Set it over a slow fire; heat it a little; then take it off again, and heat it three or four times, till it is quite hot, and then serve it up with dry toast.

ALE Conner, an officer in London, who inspects the measures used in public-houses, chosen by the liverymen in common-hall, on Midsummer day. Their places are now only regarded as sinecures for decayed citizens.

ALEE, in sea language, when the helm is moved over to the sea-side, it is said to be *alee*, or *hard alee*.

ALEMBIC, fig. 50, a chemical vessel, usually made of glass or copper, and used in distillation. The bottom part A is called the *cucurbit*, or boiler; B is the head, or capital; C is a glass-tube, through which the sublimed substances pass into D, the receiver. Retorts, and the common still worn, have entirely supplanted the alembic of the alchemists.

ALEXANDERS, a plant usually found growing wild among the rubbish of old abbeys; it was much esteemed by the monks: and to the poor who use it, affords a wholesome article of food.

ALGA, in Botany, *lichen*;—ALGÆ, *flags*, one of the seven natural families into which the whole vegetable kingdom is divided by Linnæus: they are properly plants whose roots, leaves, and stems, are all one; as sea-weeds, &c.

ALGAROTH, an oxide of antimony, obtained by washing the butter of oxymuriate with pure water.

ALGEBRA, the science of Analysis, which, reasoning upon quantity or number by symbols, examines in general all the different methods and cases that can exist in the doctrine and calculation of numbers. We have no records which enable us to determine any thing with regard to the date or author of this very important science; having arisen, in all probability, like most

others, by such slow and imperceptible degrees, that were we in possession of all the writings of the ancients, it would perhaps be difficult to draw a line, so as to determine the precise commencement of the algebraic art. The analytical method of investigating problems must have suggested itself very early to mathematicians. Those unknown quantities which are now represented by letters, were in the infancy of this science probably expressed by their names at full length, and every operation performed upon them, as addition, subtraction, multiplication, &c. were expressed in the same manner. But it would soon be found, that in this way a useless and tiresome repetition of the same words would occur in the most simple problems, whence we may easily conceive, how the idea of expressing quantities by letters first arose, which was by substituting the initial of the word for the word itself: the several operations were soon after represented in the same way; and thus by successive improvements arose this noble and comprehensive science, which in its present state does honour to the inventive genius of man.—Algebra is naturally divided into numeral, and specious or literal.

*Numeral ALGEBRA*, is that which is chiefly concerned in the solution of numeral problems, and in which all the given quantities are expressed by numbers.

*Specious or Literal ALGEBRA*, is that commonly used by the moderns, in which all quantities, whether known or unknown, are expressed by general characters, as letters, &c. in consequence of which general designation, all the conclusions become universal theorems for performing every operation of a similar nature with that for which the investigation was instituted. Every figure or arithmetical character has a determinate and individual value; as, for example, the figure 4 always represents one and the same number, namely, the collection of four units: algebraical characters, on the contrary, must be general, independent of any particular signification, and proper to represent all sorts of quantities, according to the nature of the questions to which they are applied: farther, they must be simple, and easy to describe, so as not to be troublesome in operation, or fatiguing to the memory. These advantages meet in the letters of the alphabet, which are, therefore, usually adopted to represent magnitudes in algebra. In algebraical inquiries, some quantities are assumed as known or given; and others are unknown and to be found out: the former are commonly represented by the leading letters of the alphabet, *a, b, c, d*, &c.; the latter by the final letters, *w, x, y, z*. Though it often tends to relieve the memory, if the initial letter of the subject under consideration be made use of, whether that be known or unknown: thus *r* may denote a radius, *b* a base, *p* a perpendicular, *s* a side, *d* density, *m* mass, &c. The characters used to denote the operations are principally these:

- + signifies addition, and is named *plus*.
- signifies subtraction, and is named *minus*.
- × denotes multiplication, and is named *into*.
- ÷ denotes division, and is named *by*.
- ✓ the mark of radicality denotes the square.
- ∛ the cube root.
- = equality, equal to
- :: : proportion.

Numbers are connected with the Algebraic symbols in two ways, viz.: *7x*,  $x^2$ , signifying 7 times *x*, and the second power of *x*. The figure 7 before the *x* is called a *co-efficient*, and shews how often *x* is taken; the figure 2 on the shoulder of *x* is called an *index* or *exponent*, and denotes the power of the letter it belongs to. If the exponent be a fraction as  $x^{\frac{1}{3}}$ ,  $x^{\frac{2}{3}}$ , it denotes the  $\square$  root, or cube root of *x*. *Like quantities* are expressed by the same letters with the same indices, as, *a*, *6a*, *7a*; *unlike quantities* consist of different letters, as, *a* and *b*, or *2a* and  $a^2$ . *Simple quantities* are composed of one term only, as, *a, b, 6ab, 7ax^2*, &c. *Compound quantities* consist of several terms, connected by the sign *plus* or *minus*; as *a + b, 7ax - 3b, 3ab + b - c*, &c. *Positive or affirmative quantities* are such as have the sign + before them, as, *+ a, + 6xy*. *Negative quantities* are those which have the sign — before them, as, *- a, - 6xy*. *Like signs* are all affirmative (+), or all negative (—). *Unlike signs* are composed of affirmative (+) and negative (—) signs. A *binomial quantity* consists of two terms, as, *a + b*; a *trino-*

*mial* of three terms, as, *a + b - b*; and a *quadrinomial* of four, as *a + b - c + d*, &c. A *residual quantity* is a binomial, in which one of the terms is negative, as, *a - b*. A *surd* or *irrational quantity* has no exact root, as,  $\sqrt{a}$ , or  $\sqrt[3]{a^2}$ , or  $ab^{\frac{1}{2}}$ . A *rational quantity* has no radical sign ( $\sqrt{\phantom{x}}$ ) or index annexed to it, as, *a* or *ab*. The *reciprocal of any quantity* is that quantity inverted, or unity divided by it, as,  $\frac{a}{1}$  is  $\frac{1}{a}$ , and of  $\frac{a}{b}$  is  $\frac{b}{a}$ .

—For the several operations in Algebra, as addition, multiplication, &c. see the several articles.

**ALGENEB**, a fixed star of the second magnitude in the constellation Perseus. **ALGOL**, a star of the third magnitude, in the same constellation.

**ALIAS**, in Law, a second or further writ issued from the courts of Westminster, after a *capias*, &c. has been sued out without effect.

**ALIEN**, in Law, a foreigner, one not within the king's allegiance.

**ALIENATION**, the act of making over a man's property in lands, &c. to another.

**ALIENATION**, in Mortmain, bequeathing lands to a body politic, by the king's license, else the property becomes forfeited.

**ALIOTH**, a star in the constellation of the Great Bear, much used for finding the latitude at sea.

**ALiquot Part**, (from *aliquotus*, any number of times,) is such a part of a number as is contained in it a certain number of times, and may therefore be otherwise considered as a divisor, or rather the quotient arising from division. See **DIVISION**.

**ALKALI**, in Chemistry, a particular class of salts. The alkalis at present known are these,—soda, potass, ammonia, barytes, strontia, lime, and lithium. Potass, soda, and flint, make glass: potass, soda, and oil, make soap, &c. The alkalis are incombustible, soluble in water, and possess an acrid urinous taste. They combine readily with acids, and precipitate from them the metals with which they had been previously combined. They change vegetable blues to green, red to violet, and yellow to brown. Potass and soda render oil miscible with water, and so form soap. Their peculiar crystallization when united with flint is obvious in glass.—*Potash*, a vegetable alkali, exists completely formed in the vegetable, or is produced during the operation of combustion. Potash readily combines with fat substances, and renders them soluble in water; these combinations form soap. Wine lees may be rendered almost entirely into alkali by combustion. This alkali is greenish, and is considered pure. The combustion of wine-stone also furnishes very pure alkali, but neutralized: it is known under the name of carbonate of potash, or salt of tartar. If potash and silex are fused together, the combination forms glass, but this product differs in its properties according to the respective quantities of silex and potash, of which it is composed.—*Soda*, or the mineral alkali, greatly resembles potash, and is obtained from the ashes of marine plants; as sea-weed, &c. The combination of soda, or potash, with oils or fat, forms soap; the union with potash affords soft soap, and the combination of soda with the same substances makes hard soap. Mottled soap is made by disposing the ley through the soap, or by adding to it a quantity of solution of sulphate of iron, which, by its decomposition, deposits its oxide through the soap, and gives it a variegated appearance. In some manufactories, the black oxide of manganese is made use of for the same purpose. Yellow soap is made of tallow and resin with an alkali.—*Ammonia*, or the volatile alkali, is distinguished from the former alkalis by a very sharp pungent smell, and by its great volatility. It always appears either combined, or in the state of a liquid, (liquid ammonia,) or in the aerial form, and then it is called ammoniacal gas. Its compounds are solid only when it is combined with acids.—*Barytes* has never yet been found free from all combination. It may be obtained in a state of purity by the calcination of its carbonate or nitrate, which is the heaviest mineral known. For this reason, carbonate of barytes has been termed ponderous spar. To animals it is a deadly poison.—*Strontia*, found in the state of a carbonate, that is so say, combined with carbonic acid, in a vein of lead ore, at Strontia, in Argyleshire, in

the western part of Scotland, is either of a bright green colour, or transparent and colourless.—*Lime*, called also calcareous earth, is now generally considered as an alkali, as it possesses the properties of that class of substances in a striking manner, its sparing solubility in water excepted. It is found very abundantly, though never pure, or in an uncombined state. It is always united to an acid, and very frequently to the carbonic acid, as in chalk, common limestone, marble, calcareous spar, &c. It is contained in the waters of the sea, is found in vegetables, and is the base of the bones and shells of animals. Its combination with sulphuric acid forms sulphate of lime, gypsum, or plaster-of-paris. With fluoric acid it constitutes fluuate of lime, or Derbyshire spar.—*Lithia*. For the discovery of the new fixed alkali, lithia, having for its base a new metal, (lithium,) we are indebted to M. Arfvresdon, who obtained it from petalite, a mineral which, by his analysis, was found to be composed of silica 80 parts, alumina 17, and the new alkali 3 parts. It is extracted from the petalite by calcining the latter, in powder, with carbonate of barytes, separating the earths, and obtaining the alkali combined with an acid. Its combinations with acids are, generally, very fusible. The sulphate and muriate liquefy below a red heat; the carbonate, when red-hot, acting violently on the platinum crucible. The former crystallizes readily, and retains no water of crystallization; nor is their solution precipitable by muriate of platinum, or by tartaric acid. The nitrate crystallizes in rhomboids, and attracts moisture; the muriate is highly deliquescent; the carbonate is with difficulty soluble in water; and when evaporated, the salt crystallizes in slender prisms; it has a greater capacity for saturating the acids than even magnesia. Alkalis are substances which have a great affinity for the acids; and the substances formed by the union of an acid and an alkali are called neutral salts, which have neither acid nor alkaline properties.

**ALLEGEAS**, a cotton or flax stuff, manufactured in the East Indies.

**ALLEGIANCE**, in Law, the tie or ligamen which binds the subject to the king, in return for that protection which the king affords the subject.

**ALLERION**, in Heraldry, an eagle without beak or feet, having nothing perfect but the wings.

**ALLIGATION**, in Arithmetic, is a rule by which such questions are resolved as relate to the mixing of divers merchandises, metals, simples, liquors, drugs, &c. of unequal prices, so as to find how much of each must be taken, according to the question: and Alligation is either medial or alternate. *Alligation Medial* is, when the price and quantities of several simples are given to be mixed, to find the mean price of that mixture. Rule:—As the whole composition is to its total value, so is any part of the composition to its mean price. Proof:—Find the value of the whole mixture at the mean rate, and if it agrees with the total value of the several quantities at their respective prices, the work is right.

*Example 1.* A farmer mixed 20 bushels of wheat, at 5s. per bushel, and 36 barrels of rye, at 3s. per bushel, with 40 bushels of barley, at 2s. per bushel.—I desire to know the worth of a bushel of this mixture?

$$\begin{array}{rcl} 20 \times 5 & = & 100 \\ 36 \times 3 & = & 108 \\ 40 \times 2 & = & 80 \\ \hline 96 & & 288 \end{array} \quad \text{As } 96 : 288 :: 1 : 3.$$

Ans. 3s.

*Example 2.* A grocer mixes 30 lb of currants at 4d. per lb, with 10 lbs of other currants 30 at 4d....120 at 6d. per lb.—what is the value 10 at 6d.... 60 per lb of this mixture?

$$\begin{array}{rcl} 30 & & 120 \\ 10 & & 60 \\ \hline 40 & & 180 \end{array} \quad \text{Ans. } 4\frac{1}{2}$$

*Alligation Alternate* is when the prices of several things are given, to find such quantities of them to make a mixture, that may bear a price propounded.—In ordering the rates and given price, observe,

1 Place them one under the other, and the propounded price, or mean rate, at the left-hand of them, thus,

$$\begin{array}{rcl} 18 & - & 2 \\ 20 & - & 6 \\ 24 & - & 4 \\ 28 & - & 2 \end{array}$$

2. Link the several rates together by 2 and 2; always observing to join a greater and a less than the mean. 3. Against each extreme, place the difference of the mean and its yoke-fellow.—When the price of the several simples and the mean rate are given without any quantity, to find how much of each simple is required to compose the mixture.—*Rule*. Take the difference between each price and the mean rate, and set them alternately, they will be the answer required.—*Proof*. By Alligation Medial.

*Example.* A vintner would mix four sorts of wine together, of 18d. 20d. 24d. and 28d. per quart—what quantity of each must he take to sell the mixture at 22d. per quart?

| Answer.                 | Proof. | Or thus:                 | Proof. |
|-------------------------|--------|--------------------------|--------|
| 18 ——— 2 of 18d. = 36d. |        | 18 ——— 6 of 18d. = 108d. |        |
| 20 ——— 6 of 20d. = 120  |        | 20 ——— 2 of 20d. = 40    |        |
| 24 ——— 4 of 24d. = 96   |        | 24 ——— 2 of 24d. = 48    |        |
| 28 ——— 2 of 28d. = 56   |        | 28 ——— 4 of 28d. = 112   |        |
| 14                      | 308    | 14                       | 308    |
|                         | 22d.   |                          | 22d.   |

*Note.*—Questions in this rule admit of a great variety of answers, according to the manner of linking them.

*Alligation Partial* is when the price of all the simples, the quantity of but one of them, and the mean rate, are given, to find the several quantities of the rest in proportion to that given.—*Rule*. Take the difference between each price and the mean rate as before. Then, As the difference of that simple, whose quantity is given, is to the rest of the difference severally, so is the quantity given, to the several quantities required.

*Example.* A tobacconist being determined to mix 20 lb. of tobacco, at 15d. per lb. with others at 16d. per lb. 18d. per lb. and 22d. per lb.—how many pounds of each sort must he take to make one pound of that mixture worth 17d.?

| Answer.                         | Proof. |                    |
|---------------------------------|--------|--------------------|
| 15 ——— 5 20 lb. at 15d. = 300d. |        | As 5 : 1 :: 20 : 4 |
| 16 ——— 1 4 lb. at 16d. = 64d.   |        | As 5 : 1 :: 20 : 4 |
| 18 ——— 1 4 lb. at 18d. = 72d.   |        | As 5 : 2 :: 20 : 8 |
| 22 ——— 2 8 lb. at 22d. = 176d.  |        |                    |
| 36 lb.                          | 612    | 1 lb. : 17d.       |

*Alligation Total*, is when the price of each simple, the quantity to be compounded, and the mean rate, are given, to find how much of each sort will make the quantity.—*Rule*. Take the difference between each price, and the mean rate, as before: then, As the sum of the differences is to each particular difference, so is the quantity given, to the quantity required.

*Example.* A grocer has four sorts of sugar, viz. 12d. 10d. 6d. and 4d. per lb. and would make a composition of 144 lb. worth 8d. per lb.—I desire to know what quantity of each he must take?

| Answer.                   | Proof. |                       |
|---------------------------|--------|-----------------------|
| 12 ——— 4 48 at 12d. = 576 |        | As 12 : 4 :: 144 : 48 |
| 10 ——— 2 24 at 10d. = 240 |        | As 12 : 2 :: 144 : 24 |
| 6 ——— 2 24 at 6d. = 144   |        |                       |
| 4 ——— 4 48 at 4d. = 192   |        |                       |
| 12 144                    | 1152   | (8d.)                 |

**ALLITERATION**, a rhetorical ornament, which consists of the repetition of the same letter at certain intervals; as,

"Weave the Warp, and Weave the Woof."

"Fields ever Fresh, and Groves for ever Green."

"Mountains, ye Mourn in vain, Modred whose Magic song."

**ALLIUM**, garlic, a plant with a bulbous root, much used both as seasoning and food. When bruised and applied to the skin, it causes inflammation and raises blisters. In cases of dropsy, asthmas, and agues, it is excellent, administered as a bolus, or made into pills; or pounded in a mortar, and a spoonful taken in a glass of milk. Its smell is good in female nervous disorders. Its juice makes the strongest cement for broken glass and china: placed near the haunts of grubs, slugs, &c. in the garden, it drives these vermin away.

**ALLOY** signifies the production of a baser metal mixed with a finer one. In Chemistry, we apply the term to the union of different combinations of metallic matter; as, bronze, tombac, brass, white copper, &c.

**ALLUVION**, in Law, the gradual increase of land along the sea-shore, or on banks of rivers.

**ALMAGEST**, the name of a celebrated work composed by Ptolemy, and consisting of 13 books; being a collection of many of the observations and problems of the ancients, relating both to geometry and astronomy. It contains a catalogue of the fixed stars, with their places; besides numerous records of eclipses, the motions of the planets, &c.: being the first work of the kind which has been transmitted to us, and is therefore very valuable to astronomers.

**ALMANACK**, (said to be formed of the Arabic particle *al*, and *manah*, to count,) a calendar or table, in which are noted down all the most remarkable phenomena of the heavenly bodies for the ensuing year; such as eclipses, conjunctions and oppositions of the planets, risings and settings of the sun and moon, &c.; with the return of feasts and fasts.

*Nautical ALMANACK* and *Astronomical Ephemeris*, is a national almanack, begun in 1767, under the direction, and by the advice, of the astronomer royal, the late Dr. Maskelyne. This almanac, computed a few years forward, for the convenience of ships going out upon long voyages, for which it is highly useful, contains, besides most things essential to general use, and which are found in other almanacks, many new and important particulars, as, the distance of the moon from the sun and fixed stars, computed to the meridian of Greenwich, for every three hours of time, for the purpose of computing the longitude at sea.—The astronomical day is here used, which begins at noon, and is twelve hours later than the civil day, which is counted up to 24 hours; or from sun-rise in the morning to sun-setting at night, and from sun-setting at night till sun-rise in the morning.

The *Construction of ALMANACS* is extremely easy, if you strip them of all the absurd astrology with which such as Moore's, &c. may be crammed. The first thing to be done is, to compute the sun's and moon's place for each day of the year, or it may be taken from some ephemerides, and entered into the almanac. Next find the dominical letter, and by it distribute the calendar into weeks. Then, having computed the time of Easter, by it fit the other moveable feasts; adding the immoveable ones, with the names of the martyrs, the rising and setting of each luminary, the length of the day and night, the aspects of the planets, the phases of the moon, and the sun's entrance into the cardinal points of the ecliptic; *i.e.* the two equinoxes and the two solstices.

**ALMOND**, the fruit of the almond-tree, a soft and pleasant-flavoured kernel, contained in a flattish nut. Almonds are used in confectionary and cookery; they are also eaten with raisins in desserts after dinner, but they should be well chewed, as, like all nuts, every piece you swallow entire is indigestible. The oil of almonds is much used; their milk is formed of pounded almonds, loaf sugar, and water, well mixed together, and is much used in medicine.

**ALMONDS, To burn.** Put two pounds of loaf sugar and two pounds of almonds into a stew-pan with a pint of water, and let them boil over a clear fire till you hear the almonds crack; then take them off, and stir them till they are quite dry. Then put them into a wire sieve, and sift all the sugar from them. Put the vinegar into the pan again, with a little water, and boil it; put four spoonful of scraped cochineal to the sugar, to colour it. Put the almonds into a pan; keep stirring them till they are quite dry: then put them into a glass, and they will keep for twelve months.

**ALMUCANTARS, ALMACANTARS**, from the Arabic *almocantharat*, are circles parallel to the horizon, conceived to pass through every degree of the meridian; being the same as the parallels of latitude.—*ALMUCANTAR'S Staff*, was formerly used at sea, for observing the sun's amplitude at rising or setting.

**ALOE**, a large plant, with fleshy, spinous leaves, from the centre of which, magnificent blossoms rise on stems, some twenty feet, when the tree is in a vigorous state. In Spain, where this plant is cultivated in hedge-rows, the leaves are used as scouring-paper, or their essence as soap, for it will lather in salt or fresh water.

**ALOPECIA**, a falling off of the hair from the head, &c. either from some defect in the nutritious juices, or by its vicious quality corroding the roots. A fresh-cut onion rubbed on the place till it be red and itch, is said to cure baldness.

**ALOPECURUS**, foxtail grass; one of the most productive plants of the tribe: cattle are fond of it; it grows well in moist situations, and being very early, may be cut by the middle of May. Two bushels of seed will sow an acre, with about sixteen pounds of clover.

**ALPHABET**, the several letters of a language, as A, B, C, &c.  $\alpha, \beta, \gamma, \delta$ .

**ALPHAENIX**, in Medicine, the trivial name of white barley sugar. Perhaps the name makes it valuable! The sugar is, however, good for colds, and may be easily made by boiling common sugar till it becomes easy to crack, when you should pour it on a marble slab, greased with almond oil, and then mould it into any figures you please.

**ALPHONSINE TABLES**, are astronomical tables, compiled by order of Alphonsus, king of Castile.

**ALPHONSIN**, in Surgery, an instrument for extracting bullets out of gun-shot wounds.

**ALSINE**, chickweed, the leaves of which every night fold themselves up in pairs, to protect the rudiments of new shoots; thus affording a remarkable instance of the *sleep of plants*.

**ALT**, in Music, the high notes of the scale.

**ALTAR**, fig. 51, a place upon which sacrifices were anciently offered to some deity. The altars of pagans were originally of turf, but latterly of marble, stone, &c. These altars were decorated with sculptures of the respective gods to which they were dedicated. Altars were doubtless as ancient as sacrifices, Gen. chap. iv. The altar Jacob set up at Bethel was merely a

stone; that of Gideon, a stone before his house; but, under Moses, the people of Israel had their *altar of incense*; that of *burnt-offering*, and the altar or table for the *shewbread*.

**ALTITUDE**, in Astronomy, the distance of a star from the horizon; which may be either true or apparent, according as it is taken from the true or apparent horizon.

**ALVEARIUM**, a bee-hive; also the *concha*, or hollow of the outer ear. **ALVEOLUS**, the cells of a bee-hive. In Anatomy, the sockets in the jaws, wherein the teeth are fixed.

**ALUM**, a clear transparent saline matter, of a very austere and astringent nature, useful in medicine and the arts.

**ALTERNATION**, or **PERMUTATION** of quantities or things, is the varying or changing the order of them. See **PERMUTATION**.

**ALTIMETRY**, the art of taking or measuring altitudes or heights, accessible or inaccessible, perpendicular or oblique.

**ALTITUDE**, in Geometry, the third dimension of a body, considered with regard to its elevation above the plane of its base.

**ALTITUDE of a Figure**, is the distance of its vertex from its base, or the length of a perpendicular let fall from the vertex to the base. Altitudes are divided into *accessible* and *inaccessible*. *Accessible* Altitude of an object, is that whose base we can have access to, so as to measure the distance between it and the station from which the measure is to be taken. *Inaccessible* Altitude, is when the base of the object cannot be

approached.—There are several methods of measuring the height or altitude of bodies, viz. by *Geometry*, *Trigonometry*, by *Optical Reflection*, by means of the *Barometer*, &c. The instruments commonly used in measuring altitudes, are, the *Geometrical Square*, *Quadrant*, *Theodolite*, and *Harris's Telescope*, a description of each of which will be found under the respective articles.

**Prob. 1.** *To measure an accessible or inaccessible Altitude geometrically.*—Under this head are included all those cases, in which the calculation depends upon pure geometrical principles, and particularly on the similarity of triangles, of which we propose to give an illustration in the following examples:

Let *AB* represent an object, of which the altitude is required. Being provided with two rods, or staves, of different lengths, plant the longest of them, as *FC*, at a certain measured distance from the base of the object. Then, at a farther distance, plant the second or shorter staff *ED*, in such a manner that the tops of the two, *E* and *F*, may be in a line with the top of the tower *B*. Then having measured the distance *ID*, as also the length *ED*, we shall have by similar triangles, as

that is, by multiplying the second and third terms, and dividing by the first, we shall have the whole altitude of the tower *BA*:

$$\text{that is, } BA = \frac{IA \times ED}{ID}$$

For example, suppose *IA* = 100 feet, *ID* = 8 feet, and *ED* = 4 feet, being the height of the staff; then  $BA = \frac{100 \times 4}{8} = 50$  feet,

the altitude of the tower. When the object is inaccessible, two such operations as the above must be resorted to.

**Prob. 2.** *To measure accessible or inaccessible Altitudes, by means of their Shadows.*—At any time when the sun shines, plant a rod *ab*, perpendicularly at *a*, and measure the length of its shadow, and immediately after measure the shadow of the proposed object *AB*. Then, by similar

triangles,  $ca : ba :: CA : \frac{ba \times CA}{ca} = AB$ ,

the altitude required. If the object be inaccessible, but still such that the difference of the lengths of its shadows, *ca*, *ba*, taken at two different times, can be ascertained, the altitude may be found nearly the same as in the last example.

**Prob. 3.** *To measure accessible or inaccessible objects, by means of Optical Reflection.*—Place a mirror, or other reflecting surface, horizontally in the plane of the figure's base, as at *C*, and when the object is accessible, measure the distance *CA*. Now retire back in the direction *AC* to *D*, till the eye observes the top of the object exactly in the centre of the mirror, which, for the greater degree of accuracy, may be marked by a line across it. Then having measured the distance *DC*, and ascertained the height of the eye of the observer, it will be, from the known laws of reflection, as

$$DC : DE :: CA : \frac{DE \times CA}{DC} = AB,$$

the altitude of the object required. When the object is inaccessible, that is, when the distance *CA* cannot be measured, two such operations as that above must be employed.

**Prob. 4.** *To measure an accessible or inaccessible object, by the Geometrical Square or Quadrant.* See **QUADRANT**.—Having fixed the instrument at any place *C*, turn the square about the centre of motion *D*, till the top of the object *B* is perceived in the direction of the sights placed on the side of the square *DE*, and note the number of divisions cut off the other side by the plumb line *EG*; then having measured the distance *CA*, we have, by similar triangles, as

$$EF : FG :: CA \text{ or } DH : \frac{CA \times FG}{EF} = BH, \text{ to}$$

which adding the height of the observer's eye, *DC*, we shall have

$$\frac{CA \times FG}{EF} + DC = AB, \text{ the altitude sought.}$$

**Prob. 5.** *To measure an accessible object trigonometrically.*—Let *AB* be the object of which the altitude is required. At any convenient station *C*, with a quadrant, theodolite, or other graduated instrument, measure the angle of elevation *ACB*; then, having also measured the distance *CA*, we have, from the elementary principles of trigonometry, as

Rad. : *AC* :: tan.  $\angle ACB$  : *AB*, the altitude required; or, by logarithms,  $\text{Log. } AB = \text{log. } AC + \text{log. tan. } \angle ACB - \text{log. rad.}$  Suppose, for example, the distance *AC* = 340 feet, and the angle of the elevation *ACB* =  $34^\circ 30'$ ; then, by the above formula,

$$\begin{aligned} \text{Log. } AC, \text{ or log. } 340 &= 2.5314789 \\ \text{Log. tan. } 34^\circ 30' &= 9.8371343 \end{aligned}$$

$$\begin{aligned} &12.3686132' \\ \text{Log. radius} &= 10.0000000 \end{aligned}$$

$$\text{Log. } BA = 233.67 \dots 2.3686132$$

**Prob. 6.** *To measure an inaccessible object by two stations.*—

Let *AB* be the object of which the altitude is required. Take the angles of elevation at the two stations *D* and *C*, & measure the distance between them. The angle *DBC* = the difference of the two measured angles *BCA* and *BDA*, (Euclid, prop. 16, book 1,) which angle therefore becomes known. And by trigonometry,

as  $\sin. DBC : DC :: \sin. CDB : \frac{DC \times \sin. CDB}{\sin. DBC} = CB$ .

Again, as radius : *CB* ::  $\sin. ACB : \frac{CB \times \sin. ACB}{\text{Rad.}} =$

*BA*, the altitude required. Or substituting, in the second expression, the value of *CB*, we have

$$BA = \frac{DC \times \sin. CDB \times \sin. ACB}{\text{Rad.} \times \sin. DBC}.$$

Or by *Logarithms*.—From the sum of the logarithms of the terms in the numerator, subtract the sum of those in the denominator, and the remainder will be the logarithm of the required altitude *BA*.

Immediately connected with angles of altitude, or horizontal angles, is the consideration of Mr. Harris's *Micrometrical* and *Double-image Telescope* and *Coming-up Glass*. This instrument is particularly useful at sea, or in situations when it is either difficult or inconvenient to keep an instrument in a steady position. Hence it becomes an excellent coming-up glass for ascertaining whether a ship is approaching to, or receding from, the observer. In practical astronomy it is of very extensive use, and as the minutes and seconds are, in some of the instruments, engraved on the scale, the angle is found without the

trouble of reduction. The great length of the scale too, which is generally equal to the focal length of the first object-glass, renders the use of the instrument very simple. And we give this a place here, because, under the word Telescope, we shall have enough to say on the instruments of other opticians, which are purely astronomical.

**Section I. Description of the Telescope.**—This valuable instrument, fig. 58, is divided into four parts, or drawers, of which the outer one contains a fixed object-glass at A. At C in the part CD is a moveable object-glass, which by pushing the parts BC and CD quite in, is brought into contact with the fixed object-glass at A. In this position of the drawers, distinct vision is procured by pulling out the eye-piece DE; and the magnifying power of the instrument is at its minimum or lowest degree. By pulling out the drawer CD, and afterwards the drawer BC, the magnifying power of the glass is made to increase; and when both these parts are quite drawn out, and distinct vision procured by re-adjusting the eye-piece DE, (which it will be found necessary to do every time that the position of either of the drawers is altered,) the magnifying power of the glass is at its maximum or greatest degree. In this position of the drawers two scales will be perceived thereupon; one adapted to the single object-glass above mentioned, and the other to a divided object-glass, of which a particular description will be found in the last section. By looking through the telescope, or at fig. 59, two parallel points *a, b*, are seen projecting into the field of view, as also a pair of fibres, *m n, o p*, which, with the object-glass, are essential parts of the instrument. For when it is required to measure the angle subtended by any two points of an object, in order to ascertain its distance from the observer, it is necessary that these points should be brought to coincide exactly with the steel pins, which appear as fixed points in the field of view, as before observed: which may be thus effected:—Having chosen a station which you think convenient for the observation, and two conspicuous points in the object, shut the drawers BC, CD quite in, and procure distinct vision of the points in the object, by pulling out the eye-piece DE: the points in the object will generally occupy a less space than that between the steel pins. In order that they should coincide, first draw out the part CD until they are found to do so exactly; and the milled ring at C will cut the scale at the minutes, and part of a minute, which the angle subtending the points contain. If the points do not coincide when the part CD is quite drawn out, then draw out BC until coincidence is procured; obtaining distinct vision as you proceed, and the milled ring at B will shew you the angle as before. If, when the drawers are both shut in, the points of the object occupy a greater space than the steel pins, you are too near the object, and must therefore choose two more convenient points upon it, or a more convenient station by receding from it. If, on the contrary, when the drawers are quite out, the points of the object occupy a less space than the steel pins, you are too remote from the object, and must choose either two more convenient points thereon, or a more proximate station. Observe, the drawer BC is in nowise to be touched, until CD is first quite drawn out.

**Section II. To ascertain the distance of an object either at sea or on land, by two angles and a base between them.**—When you are approaching the object, as will be oftentimes the case at sea, the first angle should be obtained when the drawers are nearly, or quite pulled out, because the angle will be increasing. But if you are receding, the angle for the contrary reason should be obtained when the object-glasses are but little apart. Let the two points of the object be called D and E, and the object C, (fig. 60,) and let the place of the first observation be called B, at which the points of the object coincide

Fig. 58.

Fig. 59.

with the steel pins *a, b*, when the object-glasses are nearly in contact; in this case, measure a receding base to A, which should be in a straight line from the object, and not less than  $\frac{1}{3}$  part of its supposed distance, reckoning from the object-glass of the telescope; and at this second station, again mea-

Fig. 60.

sure the angle subtending the points of the object. Then to find the less distance BC;—Multiply the base by the less angle, divide the product by the difference of the angles. The quotient will be the less distance. To which adding the base, you will, if it be wanted, obtain the greater distance. If, by reason of the distance of the object, the steel pins cannot be conveniently used, the parallel fibres may be taken instead, as the ratio of the angles, determined as above, will answer the same purpose as the angles themselves, when obtained from the coincidence of the steel points *a, b*, with D, E, in the object.

**Example 1.**—Wanting to know my distance from a fortification, I found the angle subtended by two prominent points thereupon to be 180 minutes, then receding 150 yards in a straight line, I again found the angle subtending these points was 140 minutes.—Now to find the distances: We have the greater angles 180', less angle 140', their difference 40'.

|                         |            |
|-------------------------|------------|
| Length of the base..... | 150 yards. |
| Less angle.....         | 140        |

|      |
|------|
| 6000 |
| 150  |

Difference of angles... 4,0)2100,0

|                    |            |
|--------------------|------------|
| Less distance..... | 525 yards. |
| Add the base.....  | 150        |

Greater Distance..... 675 yards.

**Example 2.**—Standing in shore by night towards the Lizard, I observed that the angle subtending the two lights was 40'; then standing in a direct course  $1\frac{1}{2}$  mile nearer per log. I again observed the angle to be 46',—required my distance from the light at the place of the last observation. Here greater angle 46, less angle 40, their difference 6 minutes.

|                         |                |
|-------------------------|----------------|
| Length of the base..... | $1\frac{1}{2}$ |
| Less angle.....         | 40             |

Difference of angles divisor.... 6)60

|                    |                   |
|--------------------|-------------------|
| Less distance..... | 10 miles required |
| Add the base.....  | $1\frac{1}{2}$    |

Greater distance.....  $11\frac{1}{2}$

**Section III.**—To obtain the distance of a given point from any place, when the inequalities of the ground, or proximity to an enemy's guns, render it impracticable to measure a base from that point. Let M be the given point, and C the place whose distance is wanted, (see fig 61.) Let also *a, b*, be two con-

Fig. 61.

spicuous points upon that place. Take two stations, A and B,

beyond the reach of the guns; but in the same straight line with MC, and by measuring the base AB and the angles  $aAb$ .  $aAb$ , find as in the last section one whole distance AC. Then at the point M take the angle  $aMb$ , so will the distance MC be a fourth proportional to the angles and base, that is, angle  $aMb$ : angle  $aAb$ : AC: MC. To find MC therefore, multiply the greater distance by the angle measured at the greater distance; divide the product by the angle at the given point, and the quotient will be the distance required.

*Example.*—Wanting to know the distance of a point M, fig. 61, from a tower C, and circumstances preventing my measuring a base, I took two remote stations, A and B, but in the same vertical plane with MC, and distant from each other 250 yards, at which I measured the angles A and B, subtended by two conspicuous points  $a, b$ , upon the tower: the angle  $aAb = 60'$ , and  $aBb = 92'$ ; and at M, I measured the angle  $aMb = 205'$ , required the distance: First angle B = 92, and A = 60 their diff. =  $32'$ ; and angle B  $\frac{92 \times 200}{32}$  = base 719 yards AC by the last section; then angle M, angle A:: AC: MC; or  $205': 60':: 719: 210.4$  yards.

Or as angle M ....  $205'$  arith. com. log. 7,68825  
Is to angle A .....  $60'$  log ..... 1,77815  
So is A C ..... 719 log ..... 2,85673

To M C ..... 210.4 log ..... 2,32313

Working by logarithms, which in general will be found the most expeditious method.

Section IV. *To measure the height of an accessible object.*—Let BA (fig. 62.) be an accessible object; then from a point B, as near as possible to the vertical line CBA, measure the angle  $aBb$ , subtended by two conspicuous points at the summit of the object; measure also the angle  $aCb$ , subtended by the same

points, as seen from another station C, and measure the base CB. Then to find the perpendicular. Square the greater and less angles, take the difference of the squares, and the square root of this difference. Multiply the greater angle by the base, and divide the product by the square root just found; the quotient will be the perpendicular height required. Or, if the Hypotenuse AC be wanted: Multiply the less angle by the base for a dividend, and divide by the square root above, and the quotient will be the answer.

*Example.*—Wanting to know the height of a tower, (fig. 62.) I measure from a point B near its base, the angle subtended by two points  $a$  and  $b$  at its summit, which was 150 m. I then measured 56 yards to a point C, and again took the angle between the points, and found it 180 minutes.

|                            |           |                    |             |
|----------------------------|-----------|--------------------|-------------|
| Here the greater angle.... | 180       | The less angle.... | 105         |
|                            | 180       |                    | 105         |
|                            | 14400     |                    | 525         |
|                            | 180       |                    | 1050        |
| Sqr. of Gr. angle.....     | 32400     |                    | 11025       |
| Sqr. of less angle .....   | 11025     |                    |             |
| Diff. of square.....       | 21375     | (146, 2 root       |             |
|                            | 1         | Greater angle..... | 180         |
|                            | 24)113    | Base .....         | 56          |
|                            | 96        |                    | 1080        |
|                            | 286)1775  |                    | 900         |
|                            | 1716      |                    | 146,2)10080 |
|                            | 2922)5900 | Perpen. 68,95      |             |
|                            | 5844      |                    |             |
|                            | 56, &c.   |                    |             |

It is obvious that this question, even in its most simple state, may be more readily performed by logarithms.

Thus, greater angle..... 180 Log. 2,25527  
2

Square of gr. angle..... 32400 4,51054

Square of less. angle .... 11025

Diff. of Squares ..... 21375

2

11025 Log. 4,04238

Diff. of Square Log..... 2)4,32990

Square root Log. .... 2,16495 ar. co. log. 7,83505

Logarithm of Gr. angle..... 2,25527

Logarithm of Base..... 1,74819

The perpendicular required 68,95 Log. 1,83851

Section v. *To ascertain the distance of a known magnitude.*—Let the distance between two points D and E (fig. 60.) of a distant object be known, then by choosing a station at B, so situated that the line joining these points may be at right angles to the axis of the telescope, and measuring the angle subtending these points as seen from B, we have, for ascertaining the distance of B, from the object, the following Trigonometrical Theorem: Tangent angle B: DE:: radius: the distance. Or to the Cotangent of angle B add the logarithm of DE; the sum, rejecting 10 in the index, will be the logarithm of the distance.

*Example.*—Seeing a ship, the height of whose main-top-gallant mast head I take to be 150 feet, or 50 yards above the water's edge, I measure the angle subtended by these points, which is 43 min.—what is my distance from her?

Here angle B..... 43' Log. Cotangent 11,90278

Dist. of points..... 50 Log. .... 1,69897

Distance..... 3997 Log. .... 3,60175

So my distance from the ship is 3997 yards, or  $2\frac{1}{4}$  miles nearly.

*Note.*—After any given interval of time you may again observe whether the points are still in coincidence: if they are, the angle remaining unaltered shews clearly, that you are both sailing at the same rate if they do not still coincide; but the steel pins occupy a greater space than the points of the ship, the angle is decreasing, and you are dropping astern; but if the points of the ship occupy a greater space, you are coming up; and may, by another observation, determine at what rate. It may be necessary here to observe, that any two points may be taken for the above purposes, provided that their distance from each other is known, and their position such, that a line joining them may be at right angles to the axis of the telescope: for which reason the points upon the masts are to be preferred to those upon the yards, being less liable to vary their position.

Section VI.—It has been hitherto supposed that the single object-glass, with the steel pins, has been used in the observation; these however are liable to an inconvenience at sea; which, although it will be overcome by practice, may not here be overlooked: for when the two points of an object are brought into contact with the steel pins, the slightest motion or tremor of the hand will again displace them, and thereby render the observation, to a beginner especially, exceedingly tedious. These inconveniences may however be entirely obviated, by substituting the divided object-glass for the single moveable one at C in the instrument; and of which the following description is submitted to notice:—The divided object-glass consists of two semilenses, whose centres are invariably distant; when it is used, by looking through the telescope, two images of the object will appear upon the field of view, which by turning the telescope gently upon its axis, will appear to revolve about each other, being quite separate.

if the object does not occupy more than one-third of the field of view; but, if otherwise, the images will overlap each other in a greater or less degree. Now, suppose the object ACBD, fig. 63, to be that under observation: then, if it be required to

Fig. 63.

measure the angle subtended by the part A B of the object; first draw out CD, and afterwards, if necessary, the part BC, until the points *a* and *b* of one image exactly coincide with their corresponding point A and B of the other; and the index at C or B will point out the measure of the angle subtended by these points, upon the scale for the divided object-glass. If it were required to measure the angle subtended by the points B and D of the object, it would be evidently necessary to adjust the drawers, until the point *d* coincided with its corresponding point D. It will be found, that the images have different degrees of distinctions in different parts of the field; but it will be easy to make any part of an image more distinct than another, by changing its place in the field of view, and it will contribute to the accuracy of the observation, to bring the part of the image where the contact is to be observed, into the centre of the field, it being the part where the points of contact will be most distinctly seen. As a coming-up glass, the divided object-glass possesses an eminent superiority over the single one, by reason of the steadiness with which the observation may be made: for any two points being brought into contact, neither the tremors of the hand, nor even the motion of the vessel, will displace them; its use may be illustrated as follows: When a vessel is seen at a distance, it subtends a certain angle at the eye of the observer; if the distance increases, the angle will, of course, proportionally diminish, and the contrary. Now, if the vessel be viewed through the double-image telescope, and if the drawers be adjusted until the two images of the whole, or a part of the vessel, be brought into contact; the index will cut the scale in the angle subtended by the whole, or that part. If the images continue in contact, the distance of the vessel must have remained the same; but if the images have separated from each other, the vessel must be receding from the observer, and the proportion of the distances may be found by again bringing the images into contact, finding thereby the angle anew, and thence, by the 2d or 5th section, the distance at the time of each observation. It may be also observed, that the object, or portion of an object, whose angle is to be measured by means of the double-image telescope, should be chosen as luminous as possible; or, when it can be obtained, it should be a dark object with a light ground, such as the top of a building with a sky behind it: and in measuring inaccessible distances, as by section 2, the two images of the object DE should appear separate, but as near as possible, when the observer is at B, and when the object-glass and semi-lenses are in contact.—To facilitate the observation, this instrument is sometimes constructed with one drawer instead of the two, BC, CD, which, with the eye-piece, is adjusted by means of a rack and pinion upon each, the telescope being supported upon a stand; and when it is intended to change the object-glasses in the instrument thus constructed, it will be necessary, in order to come at the moveable object-glass, to screw off the top part of the instrument about 4 inches below the principal object-glass, having first adjusted the drawer quite in. And to correct any variation which may occur in the sight of different observers, an adjustment to the stop is fixed upon the pipe containing the two first eye-glasses, by moving which, until the points and fibres are seen the most distinctly, the instrument will be adjusted to the particular eye of the observer.—We have here given a brief description of this valuable instrument, its uses and qualities, and trust, that upon trial, it will be found to exceed, rather than fall short of, the properties attributed to it. The examples which are introduced in the different sections for the purpose of illustration, as well as the rules for working them, are applicable to either the single or divided image glass; and the principles upon which these rules, as well as the instrument itself, are constructed, are demonstrated at large in Dr. Brewster's Treatise upon New Optical and Philosophical Instruments.

Analogous to the foregoing, is the *Micrometric Telescope*, which possesses all the advantages of the common telescope, is of great use for military and naval purposes, and likewise in surveying, and practical astronomy. The object of it is to measure angles and distances, which it does with great facility and accuracy. From the nature of its construction, it has also the properties of an excellent microscope. This ingenious instrument, being formed with sliding tubes, is very portable and convenient, and will be found extremely useful to military gentlemen and others, who may wish to ascertain distances without a more cumbersome apparatus.—Those of our readers who already possess achromatic telescopes, may have them converted into this instrument at a trifling expense.

ALYSSUM, madwort, a plant which was believed to have the property of curing madness.

AMABYR, an old British word, signifies, “the price of virginity,” and expresses a barbarous custom which formerly prevailed in several parts of England and Wales, being a sum of money paid to the lord, when a maid was married within his lordship.

AMADOW, the pyrotechnical sponge, a kind of black tinder, made of a species of fungus or mushroom that grows upon the bark of trees in Germany.

AMALGAM, mercury united with some metal.

AMAUROSIS, a deprivation of sight, the eye remaining fair, and seemingly unaffected.

AMBE, an instrument used by surgeons for reducing dislocated bones.

AMBER, a bituminous substance, highly electric, and much used in medicine and the arts.

AMBERGRIS, or Gray Amber, is found swimming in the Atlantic; on the coast of Brazil; in the East Indian archipelago, &c. and sometimes in the belly of the spermaceti whale.

AMBIENT, a term applied to fluids that encompass others on all sides, as the air, a flame, &c.

AMBIT, in Geometry, the perimeter of any figure.

AMBLE, the pace of a horse when his two legs on one side move at the same time.

AMBUSCADE, a place where soldiers may lie concealed till they find an opportunity to surprise the enemy.

AMERCEMENT, in Law, a pecuniary punishment, imposed on offenders at the mercy of the court.

AMERICA, the largest of the four quarters of the globe, extends from the 56th degree of south latitude to the unknown regions within the arctic circle, and from the 55th to the 165th degree of west longitude. Its length is nearly 10,000 miles, and its medial breadth about 2000. America was discovered by Christoval Colon, (or, as the Latin writers of the time call him, Christopher Columbus,) in four successive voyages: on the 12th of October, 1492, he discovered the isle of San Salvador; in 1493, the Caribbee Islands; in 1498, the continent adjacent to the Orinoco; and in 1502, a great part of the continent around Porto Bello. Amerigo Vespucci, a Florentine, and a man of science, who accompanied Colon, published the first account of the New World, and thus gave it his own name corrupted into America.—America is divided into two parts, called North and South; and these are again subdivided into separate kingdoms and states.

NORTH AMERICA is bounded on the north by the unexplored Arctic regions; on the west, by the Pacific Ocean and Behring's Strait; on the south, by the Gulf of Mexico; and on the east, by the Atlantic Ocean; that is to say, from  $7\frac{1}{2}^{\circ}$  north latitude, to  $72^{\circ}$  north latitude; or  $64\frac{1}{2}^{\circ}$ , being 3870 geographical miles; and from  $55^{\circ}$  to  $165^{\circ}$  west longitude, or  $110^{\circ}$ , being 3300 geographical miles, taking the number of miles at thirty in a degree of longitude at latitude  $60^{\circ}$ . The climate is very various; but in general, summer's heat and winter's cold are more intense than in most parts of the continents of Europe and Asia. The centre of North America is a vast fertile plain, watered by many rivers. The seas adjacent to North America are Baffin's Bay, Hudson's Bay, the gulfs of California and Mexico, and the St. Lawrence. The lakes are, Superior, Michigan, Huron, and Slave lake, between Canada and the United States. The rivers are, the St. Lawrence, the Missouri or Mississippi, Rio-Bravo, the Ohio, Red-River, and the Mackenzie. The mountains are, the Stony Mountains, the Apalachian Chain, the Iron and White

Oak Mountains. These ridges are usually marked on good maps.

**SOUTH AMERICA** extends along  $66^{\circ}$  of latitude, or 3960 geographical miles; and its breadth is  $48^{\circ}$ , or 2880 geographical miles, reckoning from Cape Blanco in the west, to Cape St. Roque in the east. Many parts of this vast continent are aboriginal and impenetrable forests, vast saline plains, regions flooded by inundations; and from the summits of the Andes, covered with eternal snow, to the torrid plains on the sea-coast, every climate is perceptible. The lakes are, Maracaybo in the north, 100 miles in diameter; Parima is 100 miles long, and 50 broad; lake Titicaca is in Peru; and in Chili is the lake of the Tehuels. The rivers are those of the Amazons, or Maranon, the largest river in the world; Rio de la Plata; the Orinoco; the Magdalena, running north to the Caribbean sea; St. Francis in Brazil, &c. The mountains are the Andes, 20,280 feet above the level of the sea, and 4,600 miles long. A chain proceeding from west to east, at nine or ten degrees north of the equator. The mountains of Parima, or the chain of the Cataracts of Orinoco, from  $3^{\circ}$  to  $7^{\circ}$  north latitude. The chain of Chiquitos, between  $15^{\circ}$  and  $20^{\circ}$  of south latitude. Between these three great ridges, three immense valleys open to the east, but shut to the west, extending from the Andes to the shores of the Orinoco, Amazons, and Buenos Ayres. Of these plains, that of Amazons is covered with impenetrable forests; while those of Orinoco, and Pampas, or Buenos Ayres, are grassy valleys or savannas, so level, that for 800 square leagues, no elevation or inequality can be seen.

**North America.**—The United States of America occupy that portion of North America which lies between the Mississippi on the west, the lakes and the St. Lawrence on the north, and the Atlantic and the Gulf of Florida wash their eastern and southern extremities. The population is above 12 millions, including 1,200,000 slaves! And it is inferred, that the population of this country doubles itself every twenty years.

The Aborigines (wild and rude tribes of savages) occupy all the part between Georgia and the river Mississippi.—The government is vested in a president, chosen every four years, and two councils or senates; the members of the superior senate being chosen every sixth year, and those of the inferior every second year. The president is a *democratical king*, in whom the executive government is vested. Each province has its government or senate, consisting of a house of representatives. The president commands both the army and the navy; the former is inconsiderable, but the latter augments with suspicious rapidity. The revenue is about twelve millions of dollars, the expenditure about ten millions; the national debt is seventeen millions sterling. The Americans are cold and reserved, evincing a contempt of strangers, and excessively

bigoted in religious matters, though their tenets are as various as schismatical invention can render Christianity. The colleges and academies are numerous, but the American booksellers reprint twenty British works for one originally transatlantic. The chief cities are, New York, Philadelphia, Charleston, and Baltimore, for commerce; and Boston for its fanatical spirit. New Orleans is situated on the Mississippi; Norfolk is the chief port of Virginia. The inland navigation of the United States is very superior, but the public roads are indifferent. The manufactures are in general in their infancy, though in some things the Americans have made considerable progress, as must be evident from the population being chiefly composed of Britons and Germans, the two most persevering mechanical nations of Europe. The climate is remarkable for sudden transitions from heat to cold; but the seasons in general correspond with those in Europe; and the soil is for the most part fertile. Three parts in four of the population are directly or indirectly connected with agriculture, which therefore thrives well; and while the southern states resemble our West India plantations, the orchards and corn-fields in the northern states bear a great resemblance to those of Lothian and Worcestershire. The rivers are, the Mississippi, the Ohio, the Illinois, the Wisconsin, the Chipaway, St. Croix, the Great and Little Miami, the Wabash, the Great Kenneway, Kentucky, the Green River, the Cumberland, and the Tennessee. Into the Atlantic flow St. Croix, Penobscot, the Kennebec, the Saco, the Merimac, the Connecticut, the Hudson river, the Delaware, the Susquehanna, the Potomac, James's river, the Shenandoa, the Black Water and Staunton, the Pedee, the Santee, the Savannah, and the Attamala. The lakes, Cedar, Little Winnepeg, and Leech, Champlain, Lake George, Oneida, Cayuga, and Sennaka. The others we have mentioned. The chief mountains are, the Apalachian, the White and Green mountains in the northern districts, the Land's Heights, the Savage and Bald mountains, and the Allegany or Blue mountains. The aboriginal forests are large and numerous; and the lake of the Dismal Swamp, 150,000 acres in extent, is covered with trees of prodigious height, choked up with brushwood, so as to render the swamp impervious. Bears, wolves, deer, and other wild animals, roam undisturbed here. The lake or marsh of Onaquafenoga, in Georgia, is 300 miles in circumference, and contains many fertile islands, one of which, called Paradise, or the Happy Isle, is inhabited by a peculiar race of Indians, whose women, from their incomparable beauty, are called the daughters of the sun. The islands belonging to the United States, are Long Island, a few insular strips of land near the shores of North Carolina, with others scattered along the coast, and in the various bays and lakes.

The Spanish Dominions in North America.—These dominions are 2200 miles in length, and about 460 in breadth; and the population amounts to eight millions, of whom four millions and a half are Indians, two millions and a half a mixed race, and one million of Spaniards. And we might divide them into East and West Florida, California, and New and Old Mexico: thus,

| <i>Divisions.</i>                 |            | <i>Rel. Sit.</i> | <i>Chief Towns.</i>                |

| Guanaxuato.....    |            | Guanaxuato.             |

The soil, produce, and climate of these dominions are thus described:—Extensive savannas feed numerous herds of cattle; the mountains abound in the precious metals; the climate is singularly diversified between the tropical seasons and rains, and the temperature of the southern, and even middle countries of Europe. The climate has a ruling influence over the diseases of these regions, among which, the yellow-fever is one of the most fatal, but it usually confines itself to sea-ports. The soil is often a deep clay, surprisingly fertile, and requiring no manure, save irrigation; but the division of land is far more unequal than in Europe, yet agriculture flourishes. The chief products are wheat, cotton, indigo, tobacco, cochineal. California is famous for fish, and a pearl fishery; and in the centre of this peninsula is a plain of rock salt, as firm and pellucid as crystal.—The province of Valladolid, the most delightful of these fertile regions, produces the pine-apple, pomegranate, fig, citron, lemon, orange, and coconut trees, sugar canes, indigo, jalap, &c. And its chief ports are Vera Cruz and Acapulco.—The kingdom of Mexico is by far the most important of these settlements, as its capital, Mexico, is the chief city of Spanish America. The population of this city is 150,000 inhabitants, and it is the seat of a vast commerce between Vera Cruz and Acapulco. Mexico is situated in a vast plain, 7475 feet above the level of the sea. The religion is the Roman Catholic, and one-fifth of the Spaniards are ecclesiastics, monks, friars, and nuns. The inquisition ruled here with fanatic fury in former times. In Mexico there is an enclosure between four walls, filled with ovens, into which are thrown the unhappy victims of the inquisition, condemned to be burned alive! There are in Mexico no remains of what our historians have fabled, and its chief remaining antiquities appear to be earthenware, ruins of dykes and aqueducts, some colossal statues, hieroglyphical pictures, weapons, and knives of sacrifice. The government of Mexico is the chief of Spanish America, and it is extended over a territory equal to an European empire. The sovereign's power extends to the patronage of all the churches, the disposal of lucrative offices, monopolies, connivances, presents; and his court, upon a regal plan, is hemmed in by horse and foot guards, while his household and numerous attendants swell the pageantry. Guatemala is ruled by a president, who is also captain-general of the troops. Each of the interior provinces has its president. The army has been computed at 40,000 men; but it is difficult to speak near truth on the revenue, and several other matters of general geography, belonging to the Spanish dominions in North America. The independence of Mexico has been formally acknowledged by Great Britain. This country is still partly ruled as formerly, but it seems probable that its government will be assimilated to that of the United States. The chief towns are, Tasco, Guanaxuato, Guatemala, Xalappa, Merida, Santa Fé, Panama, Porto Bello, and Acapulco. Tasco, situated 6000 feet above the level of the sea, is the seat of the noted mines of Moran and Oyamel. The surrounding region is covered with oaks and pines, and the crops of wheat and barley are very abundant. But Guanaxuato boasts the richest silver mines in the world; that of Valencia yielding its proprietor a revenue of £130,000 annually, and produces above half a million sterling. This mine is 280 fathoms in depth. In 1773, Guatemala was destroyed by an earthquake, and 8000 families perished; but the new city is well peopled. Xalappa is romantically situated in a fine climate, about the middle of Vera Cruz; and near it the snowy peak of Orizala, or the star mountain, rises to the sublime height of 17,390 feet above the level of the sea. In Merida, the capital, resides the governor of the province of Yucatan. Another governor resides at Santa Fé. Panama has a rich pearl fishery, and is the noted resort of merchant vessels. Porto Bello is a fine harbour, and is celebrated for its fairs, which are much frequented by merchants. And though the climate of Acapulco be sultry, it engrosses the chief Indian trade over the Pacific.

The British Possessions: Canada, &c.—Canada extends from the Gulf of St. Lawrence to Lake Winnapeg, 1400 miles; and its average breadth is about 200 miles. This country is in general mountainous and woody; but in Upper Canada there are savannas and plains of great beauty. In the lower province, the soil is a loose, black, fertile mould, of a foot thick, resting on clay. The climate is salubrious, but cold during winter, which continues eight months severe. Canada exports furs, hides, timber, fish, potash; and receives spirits, wine, tobacco, sugar, salt, and manufactured goods, chiefly from England. The established religion is the Protestant, superintended by the Bishop of Quebec. But as the French were the first possessors of Canada, there are many Catholics. The Protestant clergymen are 12, the Catholic 125, from which it appears in what ratio the Catholics outnumber the Protestants. The chief towns are, Quebec, Sorelle, Trois-Riviers, Montreal, and Kingston. Quebec, upon the north of the river St. Lawrence, is immortalized by the death of General Wolfe. The population amounts to 10,000 souls; and the adjacent country presents much sublime and picturesque scenery. From December to April, the river is frozen over here. Montreal, 150 miles above Quebec, has about 7000 inhabitants, and its chief traffic is in furs, which the traders purchase from the Indians. Kingston is situated on the Lake Ontario, at the grand egress of the river St. Lawrence. Trois-Riviers is the grand resort of the Indians, and its population is not more than 1500 souls.—The island of Newfoundland, about 320 miles in length and breadth, has, as its chief towns, St. John, Placentia, and Bonavista. The population does not exceed a thousand families during the winter. The celebrated station on the banks of Newfoundland is more than 400 miles in length, and about 140 in breadth; the water being from twenty-two to fifty fathoms, with a great swell, and frequently a thick fog. The chief fishery begins on the 10th of May, and continues till the end of September; the greatest number of cod-fish taken by a single fisherman is about twelve thousand, the average is seven thousand. The largest fish are each about four feet three inches in length, and weigh about forty-six pounds. Upwards of 500 English vessels frequent these banks, and about the same number of Americans and French.—New Brunswick is separated from the province of Maine, belonging to the United States, by the river St. Croix; and the Apalachian mountains pass along the north-west of this province. The capital is Frederick Town, on the river St. John, which affords a common and near route to Quebec. Some settlements, commanded by Fort Howe, have been established in the bay of Fundi.—Nova-Scotia is a province on the east of Canada, and south of the river St. Lawrence. New Brunswick is the more northerly, Nova Scotia the more southerly. And the Bay of Fundi, between New Brunswick and Nova Scotia, extends fifty leagues inland, the ebbing and the flowing of the tide being from forty-five to sixty feet. Halifax, the capital of Nova Scotia, contains 15,000 inhabitants; and the Bay of Fundi is remarkable for its sublime and picturesque scenery. The island of Cape Breton, close to Nova Scotia, has a cold and foggy climate, and the soil is a mere moss, unfit for agriculture. But the fur trade and fisheries, at its chief towns, Sidney and Louisbourg, are very considerable. The Bermudas, or Summer Islands, are situated about half-way between Nova Scotia and the West Indies.

Native Tribes, and Unconquered Countries.—These are, Greenland, Labrador, the regions round Hudson's and Baffin's Bays; the central parts, and the western coast. Greenland was visited by the Norwegians in the year 982, above 500 years before Colon discovered San-Salvador or Cat Island. But about 1406, about eighty-six years before Colon's discovery, by the gradual increase of the arctic ice, the Norwegian colony was completely imprisoned by the frozen ocean. This dreary region consists of rocks, ice, and snow; and in the south-west there are Danish and Moravian settlements. The botany is made up of junipers, willows, and dwarf birches. The zoology, of rein-deer, wolf-dogs, foxes, bears; sea-fowl, fish, and a few species of insects. The natives are American Samoiets, or Iskimois, short of stature, with long black hair, small eyes, and flat faces; and their numbers do not exceed ten thousand, chiefly employed in catching seals and in fishing.—Labrador,

supposed to have been discovered by the Norwegians about the year 1003, receives its name from a Portuguese navigator, who, in 1500, arrived at it in search of a north-west passage. The natives are Eskimois savages of filthy manners, and a race of mountaineers resembling gipsies, but with French features, and in their religion Roman Catholics. This country abounds in bears, rein-deer, foxes, martins, and beavers; the lakes, rivers, and pools, are rich in salmon, trout, pike, barbel, and other fishes. The bears are remarkably fond of salmon, and will assemble in numbers at the cataracts where the salmon ascend, to catch their favourite prey. Some dive after the fish, and do not appear again till at the distance of sixty or seventy yards. But they are usually successful in the pursuit. Others appear mere loungers, that have come only to see the sport, and enjoy the promenade among the surrounding alders, spruce-firs, larches, birch, and aspen-trees. Nor is it an unusual thing for two score of white bears to be present at this spectacle!—The regions round Hudson's Bay are held by the Hudson's Bay Company, and the North-West Company, both English; hence these regions have been called New Britain. The parts on the west of Hudson's Bay have also been called New North and South Wales, while that on the east, between Labrador and the bay, is called East-Main. Hudson's sea presents bold rocky shores, or marshes, and large beaches; the winters, even in latitude 75°, are extremely severe; mock suns or halos are frequent; the sun itself rises and sets with a large cone of orange-coloured light; the aurora-borealis diffuses its variegated splendour with as much brightness as the full and cloudless silvery moon; and the stars scintillate with uncommon redness. The central parts are only known, from the travels of Hearne, Mackenzie, and Franklin. These parts are inhabited by various tribes of Indians, who are chiefly employed in hunting and fishing. The animals found are those peculiar to northern latitudes; the rivers and lakes are stored with fish and water fowl; and so numerous were the herds of elk and buffaloes which Mackenzie met with, where the scenery was interspersed with hill and lawn, that the country resembled a stall-yard. The natives towards the Pacific are fairer than those of the central parts, and evince a decided superiority in the arts and in their manners. The western coast comprises all those shores stretching from Behring's Strait to New Mexico. It is bounded inland by a great chain of mountains, and the whole region is chiefly alpine, bearing a strong resemblance to Norway. The natives are savages; in some tribes mild and affable, as well as just in their dealings; in others, cruel to strangers, and brutal to their captives taken in war, as the savages of Nootka and the Mosquinas, who massacred the Franciscan missionaries; and, among the whole, the females are held in abject subordination.

The Isles of Colon, or the West Indies.—These islands are Cuba, St. Domingo or Hayti, Jamaica, Porto Rico, the Antilles, Caribbee or Leeward islands, Trinidad, and the Bahama islands.—Cuba is 700 miles long, but only 70 broad. This island is fertile, producing excellent sugar, and the famous Havannah tobacco. It is governed by a Spanish governor-general and eighteen magistrates. The chief town is Havannah, and the people are fond of bull-fights, cock-fightings, balls, and good living.—St. Domingo, or Hayti, is now an independent empire; the national assembly of France having passed decrees for the mulattoes, or people of colour, to vote for representatives, the slaves rose against their oppressors, and after many battles, have effected their independence; and the island is now governed as a republic, after the fashion of the United States of America. The products of this island are similar to Cuba and Jamaica.—Jamaica, an English settlement, is 170 miles long, and 60 broad. It is divided into three counties, Cornwall in the west, Middlesex in the centre, and Surrey in the east. St. Jago or Spanish town, is the capital, and Kingston the chief sea-port. The products are sugar, rum, coffee, indigo, ginger, pimento. The legislature consists of a captain-general, or governor; a council of twelve, nominated by the king; a house of assembly, of forty members, who are freeholders. The bread-fruit tree has been introduced. The Blue Mountains rise 7430 feet above the level of the sea.—Porto Rico, belonging to Spain, is 120 miles long and 40 broad. It is a fertile, beautiful, and well-watered island; producing

cotton, sugar, ginger, hides, drugs, and sweetmeats.—The Caribbee Islands, extending from Tobago in the south, to the Virgin Islands in the north, are of noted fertility and commercial advantage, producing sugar, cotton, rum, coffee, indigo, &c. These islands are, Barbadoes, Antigua, St. Christopher's, St. Vincent, Dominica, Grenada, Montserrat, Nevis, Trinidad, and the Virgin isles, belonging to Great Britain. The French Caribbee islands are Martinique, Guadaloupe, St. Lucie, Tobago, and some islets. The Danes possess St. Croix, St. Thomas, and St. John, attached locally to the Virgin group. St. Bartholomew belongs to Sweden; and St. Eustatius to the Dutch. Trinidad is about sixty miles long by fifty broad; the climate is delightful; and two-thirds of the soil is most fertile.—The Bahama or Lucayos Islands comprise Abaco, Bahama, Eleuthera, Providence, Cat Island or San-Salvador, Crooked Island, and Cayo. The inhabitants are whites, English and Spanish, with many negroes. These West India islands afford cotton, logwood, mahogany, the cabbage-palm-tree, rising 200 feet, the tamarind tree, with its airy elegance and acid pods, the alder, and elm; the fruits are apples, peaches, figs, grapes, pomegranates, oranges, pine-apples, cashew-nuts, cocoa-nuts, and guavas; and the spices are numerous and exquisite.

*South America.*—The extent of this continent has already been noticed. It is divided into the Spanish dominions; the Portuguese dominions; the French dominions; the Dutch territories; and the countries possessed by the native tribes. The Spanish dominions once comprised the viceroyalties of La Plata, Peru, and New-Granada, with the Caraccas, and some inferior governments. The Portuguese dominions are, Brazil, and part of Guiana; the French and Dutch were also in Guiana; and the native tribes possess Patagonia and other countries. The Spanish dominions, that is to say, the countries subject to Spaniards, whether independent, or governed by the mother country, contain a population of 4½ millions of souls; and are divided into, 1st. The Territories on the Caribbean Sea, comprising Venezuela, Cumana, Guiana: chief towns, Leon de Caraccas, Cumana, St. Thomas. 2dly. The Territories on the Pacific, comprising New Granada, Peru, Chili, La Plata: chief towns, Carthagena, Lima, St. Jago, Buenos Ayres. Venezuela is now an independent republic; a portion of Cumana is also free from the Spanish yoke; and the whole of these territories have, in our own times, been erected into independent states. (1825.)

The Kingdom of La Plata.—The kingdom of La Plata, or Buenos Ayres, may be thus described. In extent it reaches from 14° south to near 38°, that is, 24°, or 1440 geographical miles in length; and in breadth about 12°, or 720 geographical miles. The population is about 2½ millions of souls. The government was managed by a viceroy, who had also the title of captain-general, and his jurisdiction extended to the whole of the political management, except the royal treasury; which was managed by the paymaster-general of the army. The strength of the army is not considerable, but some of its native troops are expert in the spear, the rope, and the ball. In their manners, the people resemble the European Spaniards, because it has been the policy of Spain to excite the colonists to remain in the new territories; and this she did by the superlative prudence of the council of the Indies, an assembly of her most enlightened men. Indeed, the whole government of the Spanish colonies in America, has, for a series of years, been managed by this council. The chief cities are, Buenos Ayres, on the west side of the river La Plata, an agreeable place, containing 40,000 inhabitants, and may be considered the grand mart of European goods passing to Peru. Montevideo is celebrated for its harbour; Santa Fé is on the great river La Plata; Potosi is famous for its mountain of silver, which the avarice and labours of 270 years have scarcely lessened. La Paz, an elegant and clean town in the same region, trades chiefly in the noted tea of Paraguay. Mendoza, in a pleasant situation on the eastern declivity of the Andes, is in the celebrated passage through those mountains to Peru. Chucuito, on the grand Lake Titicaca, is a cheerful and convenient town, surrounded by a cold climate, but a fertile soil. Pimo is a rich and populous town; Oruro is noted for its mines; Oropesa is the capital of Cochambamba, once the granary of Peru; Santa Cruz is a famous missionary station; Jujuy is celebrated for its cattle-

trade; Salta for its annual fair in the valley of Lerma, where 60,000 mules and 6000 horses are commonly collected for sale. The commerce between Buenos Ayres and Peru is carried on by means of little waggons drawn by oxen as far as Jujuy and Mendoza, where it is necessary to have recourse to mules on account of the mountain. Commerce having increased the circulation of money, agriculture has made rapid progress amidst the fertile plains of this extensive region. In regard to its natural geography, the kingdom of La Plata boasts of noble rivers, as the Parana or La Plata, the Paraguay, the Uruguay, and the Mendoza. The Mendoza has pierced a hill, and formed a natural bridge, over which three waggons may pass abreast. And its lakes are generally salt; but some are sweet water, and that of Titicaca is celebrated for an island in which the Incas dedicated a temple to the sun. The Indians have a tradition, that when the Spaniards entered the country, great treasures were thrown into this lake, and among others the great chain of gold, so long that 6000 men danced in the ring it formed. The mountains of Cordova, by some regarded as a branch of the Andes, are covered with perpetual snow. In the botany of La Plata, we find the cinchona, or Jesuits' bark, rhu-barb, jalap; the carob tree, which in winter affords a palatable drink and food to both man and beast; the tea of Paraguay, composed of the leaves of a small tree resembling the orange. In the zoology of this country, we find the American camel, or native sheep, from the wool of which a most elegant and durable cloth is manufactured; the American tiger or *jaguar*, and the *puma* or lion; the wild cat, the elk, the ant-bear, a kind of deer, hippopotami; the condor, an immense bird with a red crest, and black body spotted with white; the Paraguayan ostrich, partridges, serpents of prodigious size, &c. The mineralogy of this kingdom is extensive, and lucrative beyond all belief; for not to speak of Potosi, the mines of gold and silver are innumerable. In the province of Chaco, a mass of native iron, perfectly malleable, has been found. Near Jujuy is the hall of Bolus, a singular volcano, whence the winds rush out with overbearing whirls and clouds of dust. Not far from Cordova pent up winds issue out with violence by small apertures from the rocks, and produce a noise resembling the discharge of artillery at the siege of a fortress. And in the town itself, during a still night, the inhabitants hear passing, as it were from street to street, a dull murmur, like the noise produced by thumping with a wooden pestle in a huge mortar.

**Kingdom of Peru.**—Peru borders on New Granada on the north; on the north-east it joins the Pampa del Sacramento; on the east, the savage nations of the Pajonal; and on the south-east, the kingdom of Buenos Ayres. Its length has been computed 423 geographical leagues, and its breadth 80 leagues. The provinces are forty-two, but only a few have been described, though, among the native nations of America, the Peruvians are by far the most interesting. The number of towns and villages exceeds 1500. Like the other governments of Spanish South America, the viceroyalty of Peru consisted of two branches, political and ecclesiastical. The archbishop of Lima has four suffragans, and besides the chapters of these bishops, there are 557 curates of the royal presentation. In the Peruvian valleys between 5° and 15°, no rain falls, but vegetation is supported throughout this region by liberal dews. The high table-lands of the Andes, at the height of 10,000 feet above the level of the sea, enjoy a perpetual spring united with an eternal autumn; the fields are always verdant, the grains ever wave in golden harvests; and the fruit-trees are in blossom, in ripening, or in matured fruit. The chief cities are, Lima the capital, containing a population of 52,000 souls, and carrying on a great commerce with all parts of the world, by means of intermediate agencies: Cuzco, the second city, once the seat of the Peruvian monarchy, and having a population of 26,000 inhabitants. Lima is the maritime, Cuzco the inland, capital. The other cities are, Arequipa, Guamanga, Truxillo, Arica, Oropesa, Jauja, Lambayeque, Caxamarca, Ica, and Guanuco. Truxillo is subject to earthquakes; for unluckily the earthly paradise of the Andean table-land is in many places but an insidious soil, encrusting subterranean fires of sulphureous, alkaline, and aqueous matters, in perpetual fusion, to pour forth tremendous showers of destructive lava. The botany of Peru and Chili is extensive and various, for while the valleys

on the sea-shore boast the common tropical plants, the milder plains on the Andean table-land are favourable to plants of a hardier constitution. The zoology of Peru differs little from that of La Plata; the mountain cat, a species of deer, foxes, bears, wolves; a sea-fowl with feathered body and membranous wings like the bats. The flamingo frequents the lakes. The silk-weaving spider, as large as a crab, and with teeth like a rat's, abounds in Jaen. In short, the whole country of Peru is one vast field of natural curiosities.

**The Kingdom of New Granada.**—New Granada extends from 3½° south latitude, to 12° north latitude, or 15½°, being 930 geographical miles: and the medial breadth has been assumed at 240 geographical miles. The provinces are twenty-four in all, and the following is their natural geography:—The province of Jaen de Bracumoras, the most southern, producing gold, cotton, chocolate, and tobacco. The district of Cuenca, situated on the table-land of Quito, is of benign temperature, producing abundance of cattle, sugar, cotton, and grain. Macas, a considerable province on the eastern declivity of the Andes, has a warm and moist climate, and produces cotton, sugar, tobacco, and cinnamon. Riobamba, noted for the earthquake of 1797, when only 400 persons escaped out of 9000! Guayaquil is celebrated for its commerce. Terra Firma is a name given to Panama; and the province of Darien is extended on both sides of the gulf so called. Santa Fé enjoys a perpetual spring, and the abundance of nature may be presumed, from the fact, that here there are two harvests. San Juan de los Llanos consists of prodigious plains, of a fertile soil, and containing an abundance of cattle, with some gold mines. Antioquia is chiefly celebrated for its gold mines. Quito enjoys an uniform temperature; and the capital of the same name is famous as being the place where the French mathematicians measured a degree of the meridian. Popayan enjoys a perpetual spring, and abounds in fruits. The people of this province are noted for their integrity. Carthagena is noted for its European fashions, imported since its increasing commerce, wealth, and luxury. Santa Marta is famed as the province in which the Andes terminate. The chief rivers are the Magdalena and the Cauca. Some of the most useful vegetable productions have been already mentioned, as belonging to the other kingdoms; but there are plants peculiar to the Andes, whose genera, species, and nomenclature, belong not to this work. In the zoology, we find the tapir, an animal resembling a cow, but about the size of an ass; wild boars, deer, ant-eaters, the jaguar, the puma, wild cats, serpents, and alligators. In the mineralogy of New Granada, we find the rich gold mines of Choco and Antioquia; the silver mines of Marquetones; the emerald mines of Muzo; and the copper mines of Velez. Among the natural curiosities may be mentioned the vertical cataract of Bogota, precipitating its waters from a height of 300 fathoms. This cataract is the river Feunza, which, after passing along a narrow channel on a high table-land, is poured as from the spout of a vase in one arch of 1320 feet. The noise from the fall in the basin below, the spray, the clouds of vapour, the rainbows, the surrounding picturesque scenery of trees and shrubs, render the cataract of Tequendama one of the wonders of the world!

**The Government of the Caraccas.**—This government includes Venezuela, Maracaibo, Varinas, Cumana, (including Barcelona,) Spanish Guiana, and the Isle of Margarita. This government is now considered the republic of Venezuela, and therefore we shall notice the rather, its products, commerce, cities, and natural geography. Singular as it may appear, there are rivers in this district which rise on the sea-coast as it were, and flow inward. Bees, horses, and mules, pasture in the interior; the vales alone are fertile. The cultivated articles are chocolate, indigo, and tobacco; but Hayti used to yield ten times the produce of the Caraccas. The great ports are Guayra and Porto Cavello, but the commerce is inconsiderable, and for a long time the greatest contraband trade was carried on. The chief towns are, Caraccas the capital, which, though enjoying a perpetual spring, was lately injured by an earthquake. Porto Cavello, an unhealthy place, and dangerous of access to the crews of foreign vessels. Valencia, a neat town; Maracay, a beautiful village, in the rich vale of Arago; Tulmero, in the same vale, a handsome town; Victoria, Coro, Cararo, Barqui-

simeto, Tocuyo, Guanana, Calabosa, Pao, San-Philippi, and Nirgua, are all places of minor importance. Cumana used to form a delegated government, consisting of the two provinces of Cumana and Barcelona. Cumana is subject to frequent earthquakes. Barcelona is noted chiefly for its breeding of swine; and the isle of Margarita as a military station, for the invasion of the Caraccas. The town of Maracaibo is rather unhealthy, and the thunder storms are terrible, but without them earthquakes prevail. The tobacco of Varinas is highly celebrated. The lakes are Maracaibo, famous for its mineral pitch, which at night serves, by its bituminous ignited vapours, as a lantern or pharos to the Spaniards and Indians; and the lake of Valencia, which, though receiving twenty rivers, discharges its superfluous waters by a subterraneous tunnel of evacuation, and nourishes amidst its swampy waters monstrous lizards, on which the natives feed. The rivers are, Orinoco, Aphuro, the Portuguesa, the Guarico, the Unari, and the Guarapicha. In the interior of Cumana there is a cavern called Guacharo, famous among the Indians for being of immense extent, and serving as a habitation for thousands of a kind of nocturnal birds, (or goat-sucker,) which the Indians suppose to be the souls of their ancestors. This remarkable cavern is therefore visited with great ceremony.

Spanish Guiana.—Spanish Guiana is the province which, in some maps, the geographers call New Cumana, or New Andalusia. The territory of Guiana is bounded by the Orinoco, and the Negro rivers in the west and north; on the south by the Maranon; on the east by the Atlantic ocean. The part of Brazil on the north of the river Maranon, is called Portuguese Guiana. Spanish Guiana is bounded on the south-east by Dutch and French possessions; on the south, by the Portuguese; on the west, by the Rio Blanco, or rather the great river Negro; and the Orinoco on the south. Guiana is the seat of a bishop: the inhabitants sleep on the terraces of their houses during the great heats.

The Kingdom of Chili.—Chili is a delightful country, extending for more than 1260 geographical miles, along the great Pacific Ocean, flanked and protected by the vast belt of the Andes, which sends forth copious rivers to irrigate this envied soil. The breadth is about 210 miles. The northern boundary is the desert of Atacama; the Andes on the east divide Chili from Cayo, in the viceroyalty of La Plata; on the south it is bounded by barren mountains; and the Pacific Ocean washes its western shores. The grand belt of the Andes is here 120 miles broad, with transverse ridges full of ruptures and precipices; and eight or nine paths open to the Andes on the east, like those over the Alps in Switzerland, on shelves in the perpendicular rocks, hanging over profound precipices, so dangerous and difficult, that the steadiest mule ceases to be useful in those situations. The four seasons, in an inverted order, are as regular in Chili as in Europe. The fertility of the soil may be inferred from the fact, that a great part of it was in constant labour long before the Spaniards visited Chili, and to this day manure is unnecessary, for it yields, in general, from sixty to seventy-fold! and, what is singular, in a country wherein the soil, after a lapse of ages, and the avarice of man, has so little degenerated. Chili is the seat of the richest metallic ores; lead is found, of excellent quality; iron abounds, but it is neglected; the copper is perhaps superior to the British. The provinces of Santiago, Aconcagua, Coquimbo, and Copiapo, are celebrated for their silver mines; nor is there a mountain or hill which yields not gold, the purest in the world. With such a fertile soil, and enjoying so delightful a climate, the botany of Chili partakes of the plants of both hemispheres. Nettles, as in Europe, also our potherbs and fruits; and the sugar cane and sweet potato, and other tropical plants, flourish in the northern parts of this fine country. Our fine white strawberry, tipped with purple, and three inches in circumference, is derived from Chili, where it is cultivated as a crop; wild tobacco, sudorific and febrifuge plants; incense, equal to that of Arabia; balsam, excellent, both as an odour and a curative medicine. In the zoology, reptiles are rare; the seas abound in fish, the shores in lobsters and crabs, with oysters, seals, sea-cows, and innumerable aquatic fowls; and the hills in bees. The flamingo decorates the rivers, the humming bird the groves of flowers. The ostrich in Chili is equal

to that of Africa; vultures and eagles, and condors, haunt the frightful precipices of the Andes. And amongst the quadrupeds we find dogs, hippopotami, foxes, lions of America; a singular wild horse, with cloven feet; and most of the European animals have improved in Chili. The most singular phenomenon, connected with the natural history of Chili, is the fact, that the ocean is retiring very rapidly on this coast, leaving curious grottos, hung with shells; and, in two instances, detached masses of white marble, scooped out like churches. The aboriginal Chilese are the Arancans and the Puelches. The former are the genuine representatives of the ancient Chilese; the latter, more rude and savage than the other natives, inhabit the mountains, and often change their abode, like the pastoral tribes of Asia. The Arancans have little beard; they are intrepid in war, hardy to endure fatigue, faithful to promises; but addicted to some of the savage vices. The Puelches are bold in war, faithful as allies, and may still be considered the unconquered Chilese. Such is the natural geography: the political is very brief.—Spanish Chili is divided into thirteen provinces, Copiapo, Coquimbo, Quillota, Aconcagua, Melipilla, Santiago, Rancagua, Colchagua, Manli, Itata, Chillau, Puciancy, and Huilquilema. They also possess Port Valdivia, in the country of the Cuchi, the Archipelago of Chili, and the island of Juan Fernandez. The entire government is managed by a captain-general; each of the provinces is ruled by a prefect, or corregidor. There are two vast bishoprics, Santiago and Concepcion, both suffragans of the Archbishop of Lima. The inquisition prevails at Santiago. The population is singularly mixed; wealth is wasted on dress, and equipages and titles of Castile; a countship being sold at so much, a marquise at so much more, and the want of money alone prevents the whole people from being a nation of dukes. Chili is the original seat of vaccination; and among its medicinal herbs the *vira-vira* expels the ague; the *payco* assists indigestions; the *culen* supplies an excellent tea, known as a vermifuge; and the *palqui* is esteemed a superior febrifuge to Peruvian bark.

Brazil, and the Portuguese Possessions.—The Portuguese possessions extend from the frontier of Dutch Guiana, in latitude 3° north, to Port St. Pedro, in latitude 32° south. These 35° of latitude give us 2100 geographical miles for one dimension, and the other extent is even more, reckoning from Cape St. Roque to the settlement of St. Paul de Omaguas, on the river Amazons. The chief city of Brazil is San-Salvador, but Rio-Janeiro is more celebrated for its commerce; and the chief settlements are Para-Cano, on the estuary of the Maranon; Pernambuco, Sergippe, Paraiba, Villa-Grande, &c. But the whole territory of Brazil is now divided into eight independent governments, besides that of Rio-Janeiro; and the whole is now under the immediate eye of the Emperor, of the family of the king of Portugal. The population is estimated at 250,000 whites; 600,000 negroes; and 1,050,000 of natives. The climate in the south is delicious, and the soil fertile; but the north is exposed to rains, thunder, and storms. The valleys are rich, the forests extensive, and the rivers and mountains are both numerous and grand. The productions are, Brazil-wood, ebony, and dye-woods; esculent plants, common to the tropical climes; raisins, cotton, coffee, rice, pepper, and fruits. The European settlers are gay, and fond of pleasure; their domestics and labourers are slaves; and the indigenes are irreclaimable savages, muscular and active. Rio-Janeiro has a capacious and excellent harbour, protected by the castle of Santa-Cruz; yet both here, and in the other towns, the ceremonies of religion have degenerated into a vulgar worship of images. The mines of diamonds, in the province of Serro-de-Frio, and about latitude 17°, (and thus corresponding with the celebrated diamond mines of Visapour, in Hindostan,) are very much famed, though the brilliants they produce are much inferior to those of the East, being of a brownish obscure hue, and not of so fine a water. But diamonds are baubles in comparison of the valuable herds of wild cattle which range the forests of Brazil, and the medicinal plants of high estimation, that grow spontaneously, and in abundance.

The French Settlements in Guiana.—These settlements extend about 350 miles in length, by 240 in breadth; and the chief town is Cayano, whence the whole territory is called

**Cayenne.** The soil and climate are good, the Cayenne pepper is well known; and the other products are, sugar, cocoa, vanilla, and indigo.

**The Dutch Possessions.**—These are Dutch Guiana, called also Surinam, in length 350 miles along the coast of the Atlantic, by 160 in breadth inland. The chief towns are, Paramaribo, on the west bank of the Zeeland river; and Demarara, on the river Esiquibo. It was this country that the unfortunate Raleigh attempted to penetrate, by the river Caroni, to the lake of Parima, whose sands were fabled of gold dust, and in the vicinity of which was the golden city of Manoa del Dorado. In the botany of Surinam we may notice its palms, of majestic height; the quassia; the castor-oil nut; ipecacuanha; caoutchouc, or Indian rubber; and poisonous trees and climbers abound. The entangled forests, and the swamps, are the sure retreats of panthers, serpents, and abominable reptiles.

**Native Tribes and Unconquered Countries.**—The internal nations are, the Abipons, a warlike tribe, and chiefly cavalry; the Mocobs; the Tobas; and the Aucas, in the same quarter. Towards the southern parts are the Puelches, or Patagonians; the Araucanos; the Telmels; and the Huilliches. The Abipons bury their dead under the shade of trees; and the horses of a chief are always sacrificed at his death. The Patagonians are the wandering, but humane Tartars of South America. And they bury their dead in a sitting posture, in square pits, with their weapons and cups beside them. These pits are annually opened by the matrons, and the bones of the skeletons dressed, those of the slain horses around being supported by props. Or they transport their dead to the sea-shore, where they deposit them in tents, with the skeletons of their horses placed around.

**Islands belonging to South America.**—These are the Galapagos; the isle of St. Felix; Juan Fernandez; the archipelagoes of Guaytecas and Toledo: in the former is the isle of Chiloe, 140 miles long, and 30 broad; in the latter is the isle of St. Martin, with some Spanish factories. Terra-del-Fuego, a dreary region, inhospitable and cold; and the isle of Statenland, is divided from Terra-del-Fuego by the straits of the Mairo. These countries, though in the reverse parallel of latitude (that is to say, in  $55\frac{1}{2}^{\circ}$  south latitude,) corresponding with Newcastle-upon-Tyne, in Northumberland, are yet more cold, and more severely frozen, than Lapland, in  $70^{\circ}$  of latitude North. The Falkland isles, (or Malouins, as the French call them,) boast of two, about 40 miles square, each; but the abundance of fowl and fish, caught here, ill make up the deficiencies felt from the poverty of the soil, and the perpetual storms which vitiate the climate. The isle of Georgia, to the south-east of the Falkland islands, though a land of ice, with vales destitute of trees and shrubs, and presenting only a coarse species of grass, is inhabited by the hardy lark.

**Southern or Antarctic Continent.**—This important discovery, which will be attended with incalculable advantages to our trade in the South Seas, was made in 1819 by a Mr. Smith, master of the William, of Blythe, in Northumberland. Our South Sea traders, who, during hostilities between this country and Spain, have been subjected to the greatest difficulties and privations, will now be independent of Spain, or any other power possessing South America. Mr. Smith ran for 2 or 300 miles along this continent, which formed large bays, abounding with the spermaceti whale, seals, &c. The drafts and soundings taken by the discoverer, are in the possession of our government. The following is the brief account which has been given of this discovery:—"A Mr. Smith, master of the William, of Blythe, in Northumberland, and trading between the Rio Plata and Chili, in endeavouring to facilitate his passage round Cape Horn, in 1819, ran to a higher latitude than is usual in such voyages, and in latitude  $62.30$ . and  $60$ . west longitude, discovered land. As circumstances would not admit of a close examination, he deferred it until his return to Buenos Ayres, when he made such further observations as convinced him of the importance of his discovery. On making it known at Buenos Ayres, speculation was set on the alert; and the Americans at that place became very anxious to obtain every information necessary to their availing themselves of a discovery which they saw was pregnant with vast benefit to a com-

mercial people. Captain Smith was, however, too much of an Englishman to assist their speculations, by affording them that knowledge of his secret which it was so necessary for them to possess, and was determined that his native country only should enjoy the honour and advantages of his discovery; and on his second voyage to Valparaiso, he devoted as much time to the development of it as was consistent with his primary object, a safe and successful voyage. He ran in a westward direction along the coasts, either of a continent or numerous islands, for 2 or 300 miles, forming large bays, and abounding with the spermaceti whale, seals, &c. He took numerous soundings and bearings, draughts and charts of the coast; and in short, did every thing that the most experienced navigator, despatched purposely for the object of making a survey, could do. He even landed, and, in the usual manner, took possession of the country for his sovereign, and named his acquisition New South Shetland. The climate was temperate, the coast mountainous, apparently uninhabited, but not destitute of vegetation, as firs and pines were observable in many places; in short, the country had, upon the whole, the appearance of the coast of Norway. After having satisfied himself with every particular that time and circumstances permitted him to examine, he bore away to the north, and pursued his voyage. On his arrival at Valparaiso, he communicated his discovery to Captain Sherrieff, of his Majesty's ship Andromache, who happened to be there. Captain Sherrieff immediately felt the importance of the communication, and lost not a moment in making every arrangement for following it up; he immediately despatched the William, with officers from the Andromache, and in this stage the last letter from Chili left the expedition, with the most sanguine expectation of success, and ultimate advantages resulting from it; and if we are correctly informed, a fully detailed narrative has been forwarded to government."

—Captain Cook penetrated to a much higher latitude, and drew his conclusion from observing nothing but vast mountains of ice; yet his meridian was  $45$  degrees further to the west of New South Shetland, leaving a vast space unexplored on the parallel of  $62$ , between that and Sandwich Land, in longitude  $28$  west. He again made  $67$ , or thereabouts, but in longitude  $137$  to  $147$  west. Prowse ascended no higher than  $60.30$ ; Vancouver about  $55$ .—The Russian antarctic expedition, under Captain Bellinghausen, has, in 1819 to 1824, discovered two new islands within the antarctic circle. Both islands lie in about  $69^{\circ}$  south latitude; one of them, the isle of Alexander I. in  $73^{\circ}$  west longitude; the other, Peter Island, in  $19^{\circ}$  west longitude. Both were closely enveloped in ice, and no examination could be made of them.

**AMETHYST**, a transparent gem of a purple colour, found in the East and West Indies, and several parts of Europe. In Heraldry, the term signifies purple colour.

**AMIANTHUS**, in Mineralogy, earth flax, a fibrous, flexible, elastic, mineral, found in Germany; and by Kirwan classed along with the muriatic genus of earths, because it contains about one-third part of magnesia.

**AMMI**, Bishop's weed, the seeds of which are ranked among the four lesser hot seeds; but are scarcely otherwise made use of than as an ingredient in theriaca.

**AMMODYTES**, the sand eels.

**AMMON**, the Egyptian Jupiter, worshipped under the figure of a ram.

**AMMONIA**, a volatile alkali.

**AMMONIAC**, a vegetable, gummy, resinous juice.

**SAL AMMONIAC**, muriate of ammonia, a native salt.

**AMNIOS**, a thin pellucid membrane that surrounds the foetus in the womb.

**AMOMUM**, ginger, which is cultivated like potatoes, both in the East and West Indies. The uses of the root of this plant, both as a spice and medicine, are well known. In culinary matters, ginger is one of the best substitutes for eggs, as in making common suet dumplings, and puddings of all kinds.

**AMORTIZATION**, alienation of lands to a corporation and their successors.

**AMPELITES**, cannel coal, or candle coal. See COAL.

**AMPHIBIOUS ANIMALS**, include all animals that live with equal facility on land or in water, and some others which do

not exactly conform to this description. The amphibia, from the structure of their organs, and the power they possess of suspending respiration at pleasure, support uninjured a change of element, and endure a very long abstinence. The lungs differ in appearance from those of other animals. Numbers of amphibia possess a high degree of productive power, and will be furnished with new feet, tails, &c. when, by any accident, those parts have been destroyed. Their bodies are sometimes defended by a hard, horny shield or covering; sometimes by a coriaceous or leathery integument; sometimes by scales; sometimes they have no particular coating. The amphibia, in general, are tenacious of life, and continue to move and exert many of the animal functions, when deprived of the head itself. By far the greater part are *oviparous*, some excluding eggs, covered with a hard or calcareous shell, like those of birds; others, such as are covered only with a tough skin, resembling parchment; and in many, they are perfectly gelatinous, without any kind of external covering, as in the spawn of a frog. The amphibia are divided into *REPTILIA*, containing the amphibia pedata, or footed amphibia; and the serpentes, or footless amphibia. In the *REPTILIA*, there are four genera: 1. *Testudo*, tortoise, turtle. 2. *Rana*, frog, toad. 3. *Draco*, dragon, or flying lizard. 4. *Lacerta*, lizards, crocodile, chameleon, newt, salamander, iguana. Reptiles are characterized by breathing through their mouths; and by having feet, and flat naked ears; of this order are frogs, lizards, and tortoises. Serpents are distinguished as being without feet, but frequently armed with a deadly poison, contained in fangs resembling teeth. In cold and temperate climates they conceal themselves in winter in cavities beneath the surface of the ground, where they become torpid. Some serpents are viviparous, as the rattlesnake, the viper, &c.; but those which are innocuous are oviparous, depositing their eggs in a kind of chain in a warm situation, where they are afterwards hatched. The broad laminae on the bellies of serpents are termed *scuta*, and the smaller, or divided ones, beneath the tail, are called scales, and from these the genera are characterized.

**AMPHICROSTYLES**, a temple with four columns in front, and four in rear.

**AMPHICTYONS**, an assembly composed of deputies from the different states of Greece.

**AMPHISCII**, those who inhabit the torrid zone.

**AMPHITHEATRE**, an elliptical building, in which spectators assembled to witness spectacles of wild beasts, gladiators, &c. The nobility of Rome who courted popular favour, vied with one another in entertaining the people with these horrid amusements. Lucius Metellus, Pompey, Cæsar, Augustus, and Vespasian, with his son Titus, all erected amphitheatres. Herod of Judea erected amphitheatres both at Jerusalem and Caesarea. During the reign of Tiberius, the amphitheatre of Fidenæ fell, and buried in its ruins about 50,000 persons.

**AMPLIFICATION**, the enlarging of a narration; and the soul of discourse with the ancients.

**AMPLITUDE**, an arc of the heavens intercepted between the east and west point, and the centre of the sun or of a planet, when rising or setting; and so is either north or south, ortive or occative.

**AMPUTATION**, the cutting off a limb, &c. See *SURGERY*.

**AMULET**, a charm, talisman, or preventive against mischief, witchcraft, and diseases; and usually made of such stuff as the imagination of impostors, and the credulity of simpletons, can devise: as, a stone, or a piece of metal; an animal; the letters of the alphabet, &c.

**AMULET**, *To make an.* Put a quarter of a pound of butter into a frying pan; break six eggs, beat them a little, and strain them through a hair sieve. Put them in when the butter is hot, and strew a little shred of parsley and boiled ham scraped fine, with nutmeg, pepper, and salt. Fry it brown on the under side: lay it on your dish, but do not turn it. Hold a hot salamander half a minute over it, to take off the raw look of the eggs: stick curled parsley in it, and serve it up. Some put in clary and chives, or onions. We have eaten Amulets made both ways; and a substantial dish they make, for a long journey.

**AMULET of Asparagus**, *To make an.* Take six eggs, beat them up with cream; boil some of the largest and finest asparagus. When boiled, cut off the green and small pieces, and mix them

with the eggs, and some pepper and salt: make your pan hot, put in a slice of butter, then your eggs, &c. and send them up hot—on buttered toasts, if you please.

**AMYGDALUS**, sweet or bitter almonds. See *ALMONDS*.

**AMYLACEOUS**, a term applied to the fine flour of farinaceous seeds, in which consists their nutritive part.

**ANACLASTIC GLASSES**, sonorous glasses, made chiefly in Germany. They resemble inverted funnels, whose bottoms are as thin as the peel of an onion; and upon applying the mouth to the orifice, and gently sucking out the air, the bottom gives way with a crash, and the convex becomes concave. Breathe into the orifice, and the vessel becomes gibbous as before.

**ANACONDO**, a large and terrible snake, found in Ceylon.

**ANAGALLIS**, pimpernel; to the leaves of which many extraordinary virtues have been attributed.

**ANAGYRIS**, bean trefoil.

**ANALOGY**, a certain relation or agreement between two or more things. In reasoning, analogy serves to explain or illustrate. Every physical resemblance may be reduced to two or more equalities; and every moral resemblance to two or more identities; and these are discernible only by intellect.

**ANALYSIS**, generally speaking, the resolution of something into its constituent parts; in Mathematics, the method of resolving problems by means of algebraic equations, which consider, in a single line, what in the ordinary process would occupy pages. Analysis is divided into *finite* and *infinite*, *determinate* and *indeterminate* and *residual*. Analysis of powers. Analysis of curves, &c. Hence,

**ANALYST**, one skilled in Algebra; and

**ANALYTICS**, the science or doctrine of analysis

**ANAMORPHOSIS**, in Perspective and Painting, a monstrous projection, or representation of some image, either on a plane or curve surface, deformed or distorted; but which, in a certain point of view, shall appear regular, and in just proportion.

**ANASARCA**, a species of dropsy.

**ANASTATICA**, the rose of Jericho.

**ANASTROUS SIGNS**, in Astronomy, a name given to the *duodecatemoria*, or the twelve portions of the ecliptic, which the signs anciently possessed, but which have since been deserted by the precession of the equinoxes.

**ANATOMY**, the dissection and study of the human body, which is a compound of solids and fluids. The solids are the bones, muscles, &c.; the fluids are the blood, secretions, &c. The bones are hard, white, insensible substances, full of spongy cells and reticular fibres. The bones of every skeleton are perfectly adapted to the extremity of those with which they are connected; and this connexion forms what is called Articulation. The cartilages are white, smooth, solid, but elastic substances, whose number in the adult subject is less than in children. The periosteum, a fine membrane of a cellular texture, covers the bones at their joints, and is supplied with nerves, lymphatic vessels, &c. The marrow, a fat oily substance filling the cavities of the bones, is supplied with numerous blood-vessels from the periosteum. The marrow seems to be to the bones what fat is to the muscles. The synovial glands lubricate the joints. The ligaments tie the bones together. The *bursa mucosa* are sacs capable of confining air or any other fluid; they are placed between the tendons and the bones, or beyond these, and sometimes at the extremities, and they are lubricated by a liquid resembling that which lubricates the joints. The *skeleton*, divided into the head, trunk, and limbs, is merely an assemblage of the bones of an animal, united in their natural order. The common integuments, with their appendages, are the cuticle or scarf-skin, which invests the body every where, and covers the true skin. The *rete mucosum*, is a mucous substance between the epidermis and cuticle, which gives colour to the body; for in negroes it is perfectly black, while the true skin is of the ordinary colour. The *cutis*, or true skin, is that from which leather may be made, and has throughout its whole surface innumerable papillæ, calculated to receive the impressions of touch. Thus the rete mucosum keeps the cuticle and cutis soft, and the cuticle protects both. Insensible perspiration, or that subtile vapour exhaled from the body by the glands of the skin, becomes, by union and condensation from the atmosphere, drops of sweat, which are analogous to urine in taste and nature. Accordingly, as either of

these secretions is increased, the other is diminished. The nails cover and defend the exterior points of the fingers and toes, as hard transparent horns. The hair, growing from distinct bulbs in the skin, covers the head and different parts of the body. The cellular membrane and fat, are reservoirs of oily matter from the blood, that afford moisture to the parts with which they are connected. The muscles are the fleshy organs of motion; and are divisible into acute and insensible organs. The abdomen, or lower belly, contains the *peritoneum*, surrounding the viscera; the omentum is a cawl, or double membrane, interlarded with fat, and floating on the surface of the intestines; the stomach, a large bag lying across the upper part of the abdomen, which receives the aliment through the *oesophagus cardia*. The *oesophagus*, or gullet, resembles a funnel or canal, extending from the bottom of the mouth down to the diaphragm, or about the 11th or 12th vertebra of the back, where it terminates in the stomach. The intestines form a canal about six times the length of the body, extending from the inferior orifice of the stomach to the anus, being divided into two classes, the large and small. The mesentery is a part of the peritoneum, situated amid the intestines. The pancreas is a conglomerate gland situated behind the stomach, and serving by its liquor to dilute the alimentary pulp, and to incorporate it more easily with the bile. The liver, a glandular substance formed for the secretion of the bile, is placed in the right hypochondrium, under the false ribs.—There are various other parts of the abdomen, which, in a popular work, may be advantageously omitted. The thorax, or chest, contains the breasts, the pleura, thymics, diaphragm, trachea, the lungs, the functions of respiration, and of voice. And under this division, surgeons reckon digestion, or the voiding of the feces; the pericardium; the heart and its auricles; the blood-vessels; arteries; glands and secretions; the brain nerves; the senses and their organs, as touch, taste, smelling, hearing, vision, &c.

*Comparative ANATOMY* examines, 1st. The general variations in the organization and functions of animals. 2d. The general relations which take place among the variations of organization and functions. 3d. The arrangement of animals founded on the general difference of their organization, ascending from the simplest to the most perfect structure; 4th, the anatomy of mammalia, or quadrupeds; 5th, of birds; 6th, of reptiles; 7th, of fishes; 8th, of mollusca; 9th, crustacea; 10th, insects; 11th, worms; and 12th, zoophytes.

**ANCHILOPS**, a tumor near the inner angle of the eye.

**ANCHOR**, a crooked instrument of iron, dropped from a ship into the sea, to moor her to some particular station. In the diagram, fig. 65, *b* is a strong bar of iron, at the lower end of which are the two arms *d, e*, of equal thickness with the beam *b*, which is usually called the shank. The arms taper, and are fixed at an angle of 30 degrees; *g* and *h* are the flukes of the anchor, shaped like an isosceles  $\Delta$ . The stock is a long beam of oak at *f*, consisting of two pieces strongly bolted together, as seen in fig. 66; in which is a massive ring, to which the cable is fastened. Every ship has three principal anchors, with a cable to each; viz. the sheet, best bower, and small bower anchors.

*Method of making Anchors.*—The goodness of an anchor is of great importance, and care is therefore taken, that the metal it is made of, be neither too soft nor too brittle, the latter rendering it liable to break; and the former to straighten. The shanks, arms, and flukes, are forged separately, then the hole is made at one end of the shank for the ring, which is put into the hole of the shank, and the two ends shut together

After which, the arms are shut to the shank one after the other, and the anchor is finished. Proof is made of anchors, as of coats of mail anciently, by raising them to a great height, and then letting them fall again on a kind of iron block, placed across for the purpose. To try whether the flukes will turn to the bottom and take hold of the ground, they place the anchor on an even surface, with the end of one of the flukes, and one of the ends of the shank, resting on the surface: in case the anchor turns, and the point of the fluke rises upwards, the anchor is good. In England, France, and Holland, anchors are made of forged iron; but in Spain, and several parts of the South Sea, they are sometimes made of copper. For the proportions of anchors, the shank is thrice the length of one of the flukes, and half the length of the beam; or the length of the anchor is four-tenths of the greatest breadth of the ship. So that the shank of an anchor, in a vessel 30 feet wide, must be 12 feet long. When the shank is eight feet long, the two arms are seven feet long, measuring them according to their curvity. As to the degree of curvity given the arms, there is no rule in it; the workmen are here left to their own discretion. The anchor of a large heavy vessel is smaller in proportion than that of a lesser and lighter one: because the sea employs an equal force against a small vessel as against a great one. Supposing the extent of wood upon which the water acts, to be equal in both, yet the smaller vessel, by reason of its superior lightness, does not make so much resistance as the greater; the defect whereof must be supplied by the weight of the anchor. From hydrostatic principles, the following Table has been formed; wherein is shewn, by means of the ship's breadth within, the proportions in length of the other parts of the anchor. In this Table is represented likewise the weight an anchor ought to be for a ship from 8 to 45 feet broad, increasing by the breadth of one foot; supposing that all anchors are similar, or that their weights are as the cubes of the lengths of the shanks.

M. Bouguer directs to take the length of the shank in inches, and to divide the cube of it by 1160 for the weight, because the quotient of the cube of 201 inches, which is the length of an anchor weighing 7000 lb, divided by the weight, is 1160; and therefore, by the rule of three, this will be a common divisor for the cube of any length, and a single operation will suffice. The same author gives the dimensions of the several parts of an anchor, thus:—The two arms generally form the arch of a circle, whose centre is three-eighths of the shank from the vertex, or point where it is fixed to the shank; and each arm is equal to the same length, or the radius; so that the two arms together make an arch of 120 degrees: the flukes are half the length of the arms, and their breadth two-fifths of the said length. With respect to the thickness, the circumference at the throat or vertex of the shank, is generally made about a fifth part of its length, and the small end two-thirds of the throat; the small end of the arms of the flukes, three-fourths of the cir-

TABLE.

| BREADTH OF THE VESSEL. | Feet. | Feet.            | Pounds. |
|------------------------|-------|------------------|---------|
|                        | 8     | 3 $\frac{1}{2}$  | 33      |

|                        | 45    | 18               | 5832    |

cumference of the shank at the throat. This dimension should be greater when the iron is of a bad quality, especially if cast iron is used instead of forged iron.

**AT ANCHOR**, the situation of a ship when she rides upon her anchors.—**An Improved Anchor Launch or Boat**, for

large ships has recently been invented. In the middle of the boat a bottomless well-hole is constructed in the form of a cross, of suitable dimensions to admit the flukes of the anchor (when in an upright position) down one of the arms of the cross, and the stock of the anchor down the other. In order to send out and drop an anchor, it is lowered down into the well-hole of the boat from the bow of the ship, and, thus suspended to the boat, it is secured by lashing, so that it may be cut away and dropped at the instant it is required. Previous to lowering the anchor from the ship into the boat, the cable is slackened out, and drawn up through the well-hole; the anchor being then placed as before mentioned, the cable is fastened to the ring of it, in such manner as to be clear of the boat when the anchor falls. Several of these anchor launches are at present in use in the navy.

**ANCHOR Ground**, a bottom of sea neither too deep, too shallow, nor rocky. In Architecture, anchors are ornaments among the borillons of the Tuscan, Doric, and Ionic capitals. In Heraldry, emblems of hope, either spiritual or temporal.

**ANCHUSA**, yellow anchusa, or blue-flowered bugloss: the juice of its corolla, or flower, gives out to acids a beautiful green. An infusion of these flowers refresh the patient in hot, bilious, and inflammatory distempers.

**ANCONES**, the corners or quoins of walls, cross-beams, rafters, &c.

**ANCYLOBLEPHARON**, a disease of the eye, which closes the eyelids. If the cohesion is on the cornea, the sight is inevitably lost. If the eyelids adhere to the eye, they are to be separated by a fine knife, and their re-union prevented by injections, and lint placed between them, after dipping it in some proper liniment.

**ANCYLOGLOSSUM**, a contraction of the ligaments of the tongue: some have this imperfection from their birth; others from some disease. In the former case, the frænulum may stretch by the child's sucking, or it may be snipped by a pair of scissars, but not torn by the finger: the ulcers must be cured by surgical assistance.

**ANCYLOSIS**, a distortion or stiffness of the joints, caused by a settlement of the humours, or a distention of the nerves; and therefore remedies of a mollifying and relaxing nature are required.

**ANDANTE**, in Music, a movement moderately slow, between *largo* and *allegro*.

**ANDRACHNE**, bastard orpine.

**ANDROGYNOUS**, in Zoology, an appellation given to animals which have both the male and female sex in the same individual. In Botany, the term is applied to such plants as bear both male and female flowers on the same root.

**ANDROIDES**, in Mechanics, a figure constructed so as to imitate the actions of man, as the automaton chess-player. See **Chess**.

**ANDROMEDA**, in Astronomy, a constellation in the northern hemisphere, of which the chief is Almaac, a star of the second magnitude. The stars in this constellation are, in Ptolemy's

catalogue, 23, in Tycho's 23, in Helvelius's 47, and in Mr. Flamsteed's not less than 66. Some of the stars or Andromeda have been reckoned among the changeable stars, whose brightness varies.

**ANDROMEDA**, in Botany, March cystus.

**ANDROPOGON**, in Botany, man's beard.

**ANDRYALA**, downy sowthistle.

**ANEMONE**, wild flower, which is gently astringent.

**ANEMOMETER**, in Mechanics, fig. 68, implies a machine for measuring the force and velocity of wind. Various machines of this kind have been invented at different times, and by different persons. The following has been often experienced, and found to answer the intentions. An open frame of wood, A B C D E F G H I, is supported by the shaft or arbor I.

In the two cross pieces H K, L M, is moved an horizontal axis Q M, by means of the four sails, a b, c m, of, g h, exposed to the wind in a proper manner. Upon this axis is fixed a cone of wood, M N O; upon which, as the sails move round, a weight, R or S, is raised by a string round its superficies, proceeding from the smaller to the larger end N O. Upon this larger end, or base of the cone, is fixed a ratchet-wheel K, in whose teeth the click X falls, to prevent any retrograde from the depending weight. The structure of this machine sufficiently shews, that it may be accommodated to estimate the variable force of the wind; because the force of the weight will continually increase as the string advances on the conical surface,

by acting at a greater distance from the axis of motion; consequently, if such a weight be added on the smaller post M, as will just keep the machine in equilibrio in the weakest wind, the weight to be raised, as the wind becomes stronger, will be increased in proportion, and the diameter of the cone N O may be so large in comparison to that of the smaller end at M, that the strongest shall but just raise the weight at the greater end. If, for example, the diameter of the axis be to that of the base of the cone N O, as 1 to 28; then if S be a weight of 1 pound at M on the axis, it will be equivalent to 28 pounds when raised to the greater end: if, therefore, when the wind is weakest, it supports one pound on the axis, it must be 28 times as strong, to raise the weight to the base of the cone. If, therefore, a line or scale of 28 equal parts, be drawn on the side of the cone, the strength of the wind will be indicated by that number on which the string rests.

It is well known to philosophers, that rain, on the presence or absence of which at the different seasons of the year, vegetation, and the success of agriculture, in great measure depend, and also the temperature of the atmosphere, to whose influence both animals and vegetables are subject, arises from, or at least is strictly connected with, the various directions and velocities of winds. Nor has it escaped observation, that the primary cause of the direction of the wind from a given quarter, as well as of the velocity of its progress, is the rarefaction of the atmosphere in that tract towards which it blows. The reason why air does not rush in from all sides towards the rarefied tract, seems to me to be the inequality of its density in the surrounding tracts; for from that quarter, in which the mercury in the barometer stands highest, the air must preferably proceed. If the density be equal on all sides, as in some confined tracts, a hurricane happens: hence the advantage of ascertaining and comparing the degrees of its velocity; for, those being known, its cause, and degrees of rarefaction, may with great probability be inferred. Two causes of rarefaction are already known,—solar heat, and some internal chemical action, by which a quantity of air is converted into water, and sometimes even into a stony substance; this last being

the most sudden and complete, the rarefaction of the neighbouring air arising from it is by far the most violent, but commonly of a much shorter duration and more limited extent. An accurate measure of the velocity of wind has long been sought by meteorologists. The force of wind, to which the degrees of its velocity are proportional, is measured by that of gravity, indicated in pounds and parts of a pound avoirdupois; the calculation is grounded on the observations of Mr. Smeaton, who indeed observes, that the evidence of the velocity is not so great where this exceeds 50 miles, as when 50 or under; yet, from its agreement with other observations, I am inclined to think it fully sufficient. A velocity of 123 feet per second was observed at Petersburg, in 1741, that is, at the rate of 83·8 miles per hour. According to Lalande, the course of the trade-winds is between 6 and 7 miles an hour. Mr. Brice, (*Philosophical Transactions*, 1756, p. 226,) observed a storm whose velocity was 63 miles per hour. A fair wind at sea, is that whose velocity amounts to 20 feet per second, or 16·63 miles per hour. Bouguer found the velocity of winter storms to be about 34 miles per hour, and in summer nearly 43. *Ibid.* The distance from Holyhead to the Pigeon-house, Dublin Bay, is 70 miles; then supposing the wind to be direct, and its velocity 30 miles per hour, and if we suppose the packet-boat to assume 0·4 of the velocity of the wind, it will arrive at the Pigeon-house in 5·8 hours. Let  $W$  denote the velocity of wind in the open air, or meeting no opposition;  $D$  = the distance of the place towards which the wind tends;  $N$  the number of hours it requires to traverse that distance; then any two of these being known, the other may be found by the following formulas.

| Given. | Sought. |                   |                                                                                                                             |
|--------|---------|-------------------|-----------------------------------------------------------------------------------------------------------------------------|
| W. D.  | N.      | $N = \frac{D}{W}$ | Thus if $W = 30$ , $D = 70$<br>then $N = \frac{70}{30} = 2·33$<br>$D = 30 \times 2·33 = 70$<br>$W = \frac{70}{2·33} = 30$ . |
| W. N.  | D.      | $D = W N$         |                                                                                                                             |
| D. N.  | W.      | $W = \frac{D}{N}$ |                                                                                                                             |

A well-sailing ship assumes  $\frac{1}{3}$  the velocity of the wind. The best-sailing ship 0·4 of the wind's velocity.

The above Formulas applied to the Calculation of a Ship's Way.

| Given.    | Sought. |                       |
|-----------|---------|-----------------------|
| 0·4 W. D. | N.      | $N = \frac{D}{0·4W}$  |
| 0·4 W. N. | D.      | $D = 0·4 W N$         |
| D. N.     | 0·4 W.  | $0·4 W = \frac{D}{N}$ |

Thus the wind 30, and the distance 70 miles, then the number of hours requisite to traverse that distance will be 5·1 for  $30 \times 0·4 = 12·0$  and  $12·0 \div 70 = 5·8$  hours. Again, 0·4  $W$  being 12, and the hours, 5·8, being given, the distance 70 miles, we have  $5·8 \times 12 = 69·6$ , by the second formula. And lastly, the number of hours = 5·8, and space in miles = 70, being given, we have 0·4 of the velocity of the wind =  $\frac{70}{5·8} = 12$ ; and dividing this by 0·4, we have the rate per hour of its course in the lower atmosphere.

*Dr. Kirwan's Anemometer.* (See Plate, fig. 1.) The anemometer, with a vane or weather-cock placed on the top, to shew the direction of the lighter winds, which could not be known by the anemometer, on account of the weight of the necessary appendages annexed to it. This is raised of a sufficient height above the building, supported by a vertical axis or pole; the lower end of it passes through the roof and ceiling into an apartment below. Fig. 2. The lower part of the pole or vertical axis  $AA$ , fig. 1, more enlarged, to give a better view of the necessary appendages. The pole is made of a slender spar, such as are made use of for strong setting poles for lighters, and handles for boat-hooks, as not affected by lightning, which iron too often is, and the cause of the destruction of buildings and many lives. To this pole is fastened a frame of light wood by screws, in which the weights are confined, one on the top of another, in grooves, in such a manner as to work up and down with the greatest facility. The weights are connected together by cords, and marked 1, 2, 3, 4, &c.; the space between each, when drawn up by the force of the wind, is about one inch, as may be seen by the drawing, and

each weighs one pound avoirdupois. To the top weight is fastened a line, and passing along the pole to the top, and over a brass pulley fixed at the bottom of the square tube, under the sliding rod  $B$ , fig. 3, as far as  $a$ , and there fastened: in this sliding rod a groove or channel is cut underneath, to receive the line, so as not to impede its passage over the brass rollers,  $f, f$ . The line is composed of a number of common sewing-threads, laid in different directions, well waxed, and enclosed in a cotton case, to prevent as much as possible its extension or contraction by the changes of the atmosphere. Fig. 3. The wooden pipe or tube, two inches square, fastened on the top of the pole  $AA$ , fig. 1, open on the side, to shew the manner that the sliding rod  $B$  passes over the brass rollers  $f, f, f$ , when the wind is sufficiently strong to lift up one pound by its force on the square surface presented to it, as  $b$  and  $c$ , fig. 4. Fig. 4. The wooden pipe or tube, in which are enclosed the sliding rod, rollers, and line, from the effects of the weather. Fig. 5. The wooden frame, made of light wood, one foot square, covered over with very thin sheet brass, strongly painted, and varnished with copal. This frame is fastened to the sliding rod  $B$ , fig. 3, by means of a mortise, &c. Fig. 6. An enlarged view of the scale and index, which marks the greatest force of the wind during the absence of the observer, which is attached to the frame confining the weights, as  $G H$ , fig. 2; and being connected with the hand fastened on the top weight ( $d$  fig. 2,) raises the small weight  $e$ ; and this being counterpoised by another of equal weight, by means of a line passing over a small pulley, as represented by this figure, and also  $G$ , fig. 2, occasions the small weight, with its index, to stop at the number of pounds raised by the force of the wind, though they should fall down into their proper places on the wind's abating. The bottom of the vertical axis or pole  $F$ , fig. 2, is sheathed with a steel point, and a socket, which rest on a wooden stand or frame, as at  $D$ , fig. 1, so as to turn with ease, and avoid as much as possible any friction. In order to render this simple machine more complete, and answer the purpose of an anemoscope, as well as an anemometer, it is only necessary to apply to that part of the pole or axis, which is in the apartment, an index, and attach to the ceiling a thin deal board, or a sheet of pasteboard, with the points of the compass marked thereon.

#### A TABLE,

Shewing the Velocity of the Wind in Miles per Hour, indicated by Avoirdupois Pounds and Parts.

| Miles per Hour. | Pounds and Parts. | Denominations.   | Miles per Hour. | Pounds and Parts. | Denominations.    | Miles per Hour. | Pounds and Parts. | Denominations. |
|-----------------|-------------------|------------------|-----------------|-------------------|-------------------|-----------------|-------------------|----------------|

*Dr. Lind's Wind-gage.*—This instrument consists of two glass tubes  $AB, CD$ , (See Plate, fig. 7.) of five or six inches in length. Their bores are about four-tenths of an inch in

diameter. They are connected together like a siphon by a small bent glass tube *ab*, the bore of which is about one-tenth of an inch in diameter. On the upper end of the leg *AB* there is a tube of latten brass, which is kneed, or bent perpendicularly outwards, and has its mouth open towards *F*. On the other leg *CD*, is a cover with a round hole *G* in the upper part of it, two-tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brass *ed*, which not only gives strength to the whole instrument, but also serves to hold the scale *HI*. The kneed tube and cover are fixed on with hard cement or sealing wax. To the same tube is soldered a piece of brass, *e*, with a round hole in it to receive the steel spindle *KL*; and at *f* there is just such another piece of brass soldered to the brass hoop *gh*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*; upon which the instrument rests, and a small nut at *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it; by which it may be screwed into the top of a post, or a stand made on purpose. It has also a hole at *L*, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brass, *k*, is soldered to the kneed tube, about half an inch above the ground-hole *G*, so as to prevent rain from falling into it. There is likewise a crooked tube *AB*, (fig. 8.) to be put occasionally upon the mouth of the kneed tube *F*, in order to prevent rain from being blown into the mouth of the wind-gage when it is left out all night, or exposed in the time of rain. The force or momentum of the wind may be ascertained by the assistance of this instrument, by filling the tubes half full of water, and pushing the scale a little up or down, till the zero of the scale, when the instrument is held up perpendicularly, be on a line with the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and, turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water which the wind is capable of sustaining at that time, and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water, having its base equal to the altitude of a column of water sustained by the wind in the wind-gage. Hence, the force of the wind upon any body where the surface opposed to it is known, may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind and that of another. The force of the wind may be likewise measured with this instrument, by filling it until the water runs out at the hole *G*. For if it be then held up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. The use of the small tube of communication *ab*, (fig. 8.) is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude, than the true height of the column which the wind is able at that time to sustain, from receiving a sudden impulse whilst it is vibrating either in its ascent or descent. As, in some cases, the water in this instrument might be liable to freeze, and thus break the tubes, a saturated solution of sea-salt may be used instead of it in winter. Dr. Lind gives the following table, by means of which, from the observed height of the column of water in the gage, the force of the wind on a square foot may be determined.

For heights not given in the following table, proportional parts are taken and added: for example, if the height be 5.5,—then to 26.040, the force for 5 inches, add 2.604 the force for 0.5, the decimal part, and the sum of the two, namely, 28.645 pounds, is the answer. When a saturated solution of salt is used, allowance must be made for the difference in the weight of the fluid. The specific gravity of the solution being to that of water as 1.244 to 1, the observed height of the column must be multiplied by 1.244.

| Height of the Water<br>in the Gage. | Force of the Wind on<br>One Foot Square<br>in Pounds Avoird. | Common Designations<br>of such Winds. |

*M. Bouguer's Wind-gage.*—The instrument contrived by M. Bouguer consists of a hollow tube *AA*, *BB*, (fig. 9,) in which a spiral spring *CD* is fixed, that may be more or less compressed by a rod *FSD* passing through a hole within the tube at *AA*; then having observed to what degree different forces or given weights are capable of compressing the spiral, mark divisions on the rod in such a manner, that the mark at *S* may indicate the weight requisite to force the spring into the situation *CD*; afterwards join at right angles to this rod at *F*, a plane surface *EFE* of a given area, either greater or less, at pleasure; then let this instrument be opposed to the wind, so that it may strike the surface in the directions *VE*, *VE*, parallel to that of the rod, and the mark at *S* will shew the weight to which the force of the wind is equivalent.

*Dr. Brewster's Anemometer.*—Dr. Brewster has suggested various contrivances for measuring the force of the wind. Among these we think the following, which indicates the force by its effect in compressing a column of air in a glass tube, is the most commodious and accurate. The metal cap *AB*, (fig. 10,) bent at a right angle, is fixed upon the top of the glass tube *BC*, which communicates at *C* with another glass tube, *DE*, of a much smaller bore, with a bulb, *E*, at its end. Some mercury or other liquid is poured into the tube *BC*, and of course rises to the same level, *m*, *n*, in both tubes. When the mouth *A* is exposed to the wind, the liquid at *m* descends in the tube, and by rising in the stem *DE*, compresses the enclosed air till there is an equilibrium between the elasticity of the air and the force of the wind. To prevent the fluid from oscillating, a thin disk of wood floats on its surface at *m*. The scale of this instrument, to ensure accuracy, should be formed by actual experiment.

*Professor Leslie's Anemometer.*—It would be improper to close this article without noticing the ingenious suggestion of this philosopher, for measuring the force of the wind by its cooling power. Having found, in the course of his experiments on heat, that the cooling power of a current of air is exactly proportional to its velocity, he derived from this principle the construction of a new anemometer, which will be understood without any figure, being, to use his own words, “in reality nothing more than a thermometer, only with its bulb larger than usual. Holding it in the open still air, the temperature is marked: it is then warmed by the application of the hand, and the time is noted which it takes to sink back to the middle point. This I shall term the fundamental measure of cooling. The same observation is made on exposing the bulb to the impression of the wind, and I shall call the time required for the bisection of the interval of temperatures, the occasional measure of cooling. After these preliminaries, we have the following easy rule: Divide the fundamental by the occasional measure of cooling, and the excess of the quotient above unit, being multiplied by  $4\frac{1}{2}$ , will express the velocity of the wind in miles per hour. The bulb of the thermometer ought to be more than half an inch in diameter, and may, for the sake of portability, be filled with alcohol, tinged, as usual, with archil. To simplify the observation, a sliding scale of equal parts may be applied to the tube. When the bulb has

acquired the due temperature, the zero of the slide is set opposite to the limit of the coloured liquor in the stem; and after having been heated, it again stands at  $20^{\circ}$  in its descent, the time which it thence takes until it sinks to  $10^{\circ}$  is measured by a stop-watch. Extemporaneous calculation may be avoided, by having a table engraved upon the scale, for the series of occasional intervals of cooling."

[Other devices have been adopted by philosophical ingenuity, all of which we cannot even enumerate. Mr. Brice describes one, which has been successfully practised by himself, of measuring the velocity of the wind by means of that of the shadow of clouds passing over the surface of the earth.—Mr. Ons-en-Bray invented another, which of itself expresses on paper, not only the several winds that have blown during the space of twenty-four hours, and at what hour each began and ended, but also the different strength and velocities of each.]

**ANEMOSCOPE**, fig. 69, a machine that shews either the course or velocity of the wind. The machine which shews the course of the wind, or from what point of the compass it blows, consists of an index moving about an upright circular plate, like the dial of a clock, on which the 32 points of the compass are drawn instead of the hours. The index which points to the divisions on the dial, is turned by a horizontal axis, having a trundle-head at its external extremity. This trundle-head is moved by a cog-wheel on a perpendicular axis; on the top of which a vane is fixed, that moves with the course of the wind, and puts the whole machine in motion. The whole contrivance is extremely simple, and nothing required in the construction, but that the number of cogs in the wheel, and rounds in the trundle-head, be equal; because it is necessary, that when the vane moves entirely round, the index of the dial also make a complete revolution. An anemoscope of this kind is placed in one of the turrets of the queen's palace. The anemoscope, calculated for indicating the force, or the velocity of the wind, is the same with what most writers call an anemometer; and we have, accordingly, described several of those machines under that article. We shall here add another, constructed by the late Mr. Pickering, and published in the Philosophical Transactions, No. 473. This anemoscope,  $4\frac{1}{2}$  feet high, consists

Fig. 69.

Fig. 70.

Upon this axis turns a wooden tube; at the top of which is placed a vane, of the same materials, 21 inches long, consisting of a quadrant, quadrated and shod with an iron rim, notched to each degree; and a counterpoise of wood, as in the figure, on the other. Through the centre of the quadrant runs an iron pin, up which are fastened two small round pieces of wood, which serve as moveable radii, to describe the degrees upon the quadrant, and as handles to a velum or sail, whose vane is one foot square, made of canvass, stretched upon four battens, and painted. On the upper batten, next to the shod rim of the quadrant, is a small spring, which catches at every notch corresponding to each degree, as the wind shall, by pressing the sail, raise it up, and prevents the falling back of the sail, upon lessening the force of the wind. At the bottom of the wooden tube is an iron index, which moves round a circular piece of wood fastened to the top of the pillar on the pedestal, on which are described the 32 points of the compass. In fig. 69, this machine is shewn, where *a* is the pedestal; *b* the pillar on which the iron axis is fitted; *c* the circle of wood, on which are described the 32 points of the compass; *e* the wooden tube upon its axis; *f* the velum or sail; *g* the graduated quadrant; *h* the counterpoise of the vane. The adjoining figure, 70, *a* represents the velum; *b* the spring; *c c* the wooden radii; *d d* the holes through which the pin in the centre of the quadrant goes. Its uses are the following:—1. Having a circular motion round the iron axis, and being furnished with a vane at the top and index at the bottom, when once you have fixed the artificial cardinal points, described on the round piece of wood on the pillar, to the same quarters of the heavens, it gives a faithful account of that quarter from which the wind blows. 2. By having a velum or sail elevated by the wind along the arch of the quadrant to a height proportionable to the power of the column of wind pressing against it, the relative force of the wind, and the comparative power, at any two times of examination, may be accurately taken. 3. By having a spring fitted to the notches of the iron with which the quadrant is shod, the velum is prevented from returning back upon the fall of the wind; and the machine gives the force to the highest blast, since the last time of examination, without the trouble of watching it. The ingenious contriver of this machine tells us, that he carefully examined what dependence may be had upon it, during the storms of February 1743-4, and found that it answered exceedingly well; for that, in such winds as the sailors call violent storms, the machine had six degrees to spare for a more violent gust, before it comes to a horizontal position. It is certainly to be depended upon in ordinary weather, the velum being hung so tenderly, as to feel the most gentle breeze. There is, however, reason to fear, that the exposing of the anemoscope to all winds for a continuance, must disorder it; especially irregular blasts and squalls. It may not, therefore, be amiss, in violent squalls, for the observer to take the tube, with its vane and velum in his hand, in order to know the force of the wind; and when he has finished his observations, to carry his machine into the house, till the violence of the storm is abated, when it may be replaced in its former situation.

**ANETHUM**, dill and fennel.

**ANEURISM**, a throbbing tumor distended with blood, and formed by the dilation or rupture of an artery.

**ANGEIOTOMY**, the opening a vein or artery.

**ANGELICA**, *To Candy*. Angelica is cultivated only for the large ribs of its leaves, which are cut in May or June, and made into a candy as a medicinal plant. Take it when young, cut it in lengths, cover it close, and boil it till it is tender; peel it, and put it in again, let it simmer, and boil till it is green; then take it up, and dry it with a cloth. To every pound of stalks put a pound of sugar: put your stalks into an earthen pan. Beat the sugar, and strew it over them. Let it stand two days; then boil it till it is clear and green: put it in a cullender to drain. Beat a pound of sugar to powder again, and strew it on your angelica. Lay it on plates to dry, and set the plates in the oven after the pies are drawn.  $3\frac{1}{2}$  lbs of sugar is the proportion to 4 lbs of stalks.

**ANGINA**, an inflammation of the throat, called the quinsy.

**ANGLE**, *Angulus*, in Geometry, is formed by the opening or mutual inclination of two lines meeting in a point; such is

of a broad and weighty pedestal, a pillar fastened into it, and an iron axis of about  $\frac{1}{2}$  an inch diameter, fastened into a pillar.

the angle BAC, or BAD.—*Note.* When an angle is denoted by three letters, that at the angular point must be read in the middle. But sometimes, for brevity sake, if there be but one angle at a point, that angle is denoted by the single letter standing at that point.

ANGLES are of several different kinds or denominations, as *rectilinear*, *curvilinear*, *spherical*, *mixed*, *solid*, &c. *Rectilinear* ANGLE, is that which is formed by the meeting of two right lines. *Curvilinear* ANGLE is that which is formed by the meeting of two curve lines. *Mixtilinear* ANGLE, is formed by the meeting of a right line and curve. *Spherical* ANGLE, is that which is formed on the surface of a sphere, by the intersection of two great circles. See SPHERE and SPHERICAL Trigonometry. *Solid* ANGLE, is formed by the mutual inclination of more than two planes, or plane angles, meeting in a common point. See *Solid* ANGLE.

*Properties and Denominations of Rectilinear Angles.*—*Right* ANGLE is that which is formed by one line perpendicular to another; or that which is subtended by a quadrant of a circle; as the angle BAC. All right angles are equal to one another. An *Oblique* ANGLE is that which is greater or less than a right angle; and these are distinguished into two kinds, *acute* and *obtuse*. An *Acute* ANGLE is less than a right angle, as DAC. An *Obtuse* ANGLE is greater than a right angle, as EAC. *Adjacent* ANGLES, are the two angles formed by one line meeting another, any where, except at its extremities; such are the two angles BAD and BAC. These angles are said to be supplements to each other, their sum being equal to two right angles. *Vertical*, or *Opposite* ANGLES, are such as have their legs mutual continuations of each other; as BAC and DAC. *Vertical*, or *opposite* angles, are equal to each other.

*Alternate* ANGLES, are those made on the opposite sides of a line cutting two other lines; as AFG and DGF. And if these two lines are parallel, the alternate angles are equal. *External* ANGLES, are those formed by the sides of any right-lined figure, and the adjacent sides produced; such are the angles A, B, C, &c. The sum of all the external angles of any figure is equal to four right angles. *Internal* ANGLES, are the angles within a figure, formed by the meeting of each two adjacent sides; as the angles *a*, *b*, *c*, &c. The sum of all the inward angles of any right-lined figure, is equal to twice as many right angles, wanting four, as the figure has sides. An ANGLE at the Centre of a Circle, is that whose angular point is at the centre; such as the angle ACB. An ANGLE at the Circumference, is that whose angular point is in any part of the circumference; as the angle ADB. An angle of the centre is double an angle at the circumference, when both stand on the same arc. An ANGLE in a Semicircle is an angle at the circumference contained in a semicircle, or standing upon a semicircle or diameter; and it is a right angle. An angle in a segment greater than a semicircle, is less than a right angle. An angle in a segment, less than a semicircle, is greater than a right angle. Angles of other denominations are used by some authors, as, the *Horned* ANGLE, formed by the circumference of a circle and a right line; *Lunular* ANGLE, formed by two curve lines, one concave and the other convex; and *Cissoid* ANGLE, the inward angle, formed by the intersection of the two spherical convex lines.

Problems.—1. To bisect a given Angle, BAC. From the centre A, with any radius, describe an arc cutting off the equal lines AD, AE; and from the two centres D, E, with the same radius, describe arcs intersecting in F, then draw AF; which will bisect the angle as required.

2. At a given point A in the line AB, to make an Angle equal to a given Angle C. From the centres A and C, with any one radius, describe the arcs DE, BG; then with the centre B, and radius DE, describe an arc cutting BG in G. Through G draw the line AG, and it will form the angle required.

3. To Measure the Quantity of an Angle on Paper.—Apply the centre of a protractor to the vertex of the angle, so that the radius may coincide with one of the lines; and the degree shewn by the other line, will give the measure of the angle required.

Otherwise with the Line of Chords.—With a radius equal to the chord of 60°, describe an arc between the lines forming the angle; then apply the subtense of this arc to the same scale of chords, and it will give the measure sought.

ANGLES, in Astronomy, receive the following particular denomination: as ANGLE of Commutation, of Elongation, of Position, &c.; for which, see the respective terms.

ANGLES, in Mechanics and Optics, also receive particular denominations, and are distinguished into separate orders; as ANGLES of Direction, Elevation, Inclination, Inflection, Incidence, Refraction, &c.; for which, see the respective terms. *Optic* ANGLE, is the angle included between two rays, drawn from the two extreme points of an object to the centre of the pupil of the eye.

ANGLING, among sportsmen, is the art of fishing, either with bait or flies, and a rod and line. The great secret of angling with bait is, to attract the fish to some particular spot by throwing in grains, chopped worms, &c. if the water is still; or if running, by enclosing a large quantity of worms in a tin box full of holes, by which the worms may crawl out and attract the fish. The anglers stand, sheltered by some bush or tree, as particularly at deep-water gullies, sluices, mill-dams, or ponds where the cattle go to water. Chub love deep shaded holes; eels are found under the banks of rivers and ponds; perch, in clear water and a swift stream; so are roach and trout found in quick currents; breams in deep quiet places. The best season for angling, is from April to October. A cloudy day, after a bright moonlight night, is good for fishing. Cool weather in summer, and warm weather in winter, are the fit seasons, from three till nine in the morning, and from three till sun-set in the afternoon. A southerly wind, in a dull warm day, is the best time of any

ANGOLA PEA, pigeon pea.

ANGOR, a concentration of natural heat; the consequence of which is, a pain of the head, palpitation, and sadness.

ANGUINEAL HYPERBOLA. See HYPERBOLA.

ANGULAR, something relating to, or having angles. Angular objects at a distance appear round.

ANGULAR Motion, is that which is performed by an oscillating or vibrating body, as referred to the angle which it describes or passes over in a given time, the vertex of which is the point of suspension, or centre of motion. Hence all points in a pendulum have the same angular motion, although their absolute motions are different from each other, being greater or less, according to their distance from the centre of suspension. ANGULAR Motion is also sometimes used to denote a motion which is partly curvilinear, and partly rectilinear; as the motion of a coach-wheel on a plane. ANGULAR Sections, a term used by Vieta to denote a species of analytical trigonometry, relating to the law of increase and decrease of the sines and chords of multiple arcs.

ANIMAL, in Natural History, an organized and living body, endowed with sensation. Minerals increase; plants grow and live; but animals have the power of locomotion, of seeking and appropriating nourishment.

**ANIMAL Flowers**, or Sea Nettle, or Sea Anemone, fig. 81, is a fleshy substance, endowed with claws, stomach, mouth, &c. and found adhering to rocks in the sea by one end, and with the other voraciously devouring whatever food comes in their way.

**ANIMAL Substances**, in Chemistry. The constituent principles of animal substances are nearly the same with those of the vegetables; the former, however, contain more of nitrogen and phosphorus; the latter, more of carbon and hydrogen. The complex constituent parts of animal substances are the following:—1. Gelatine. 2. Fibrin. 3. Albumen. 4. Animal oils. 5. Bone. 6. Blood. 7. Milk. 8. Horn. 9. Phosphorus and animal acids.—Gelatine, or animal jelly, very generally dispersed through all the parts of animals, even in bones, exists in the greatest quantity in the tendons, membranes, and the skin.—Fibrin, or animal fibre, forming the basis of the muscular or fleshy parts of animals, is fibrous in its structure, transparent, and insoluble in water and alcohol, except by a long continued heat in a Papin's digester.—Albumen is the principal constituent part of the serum of blood; it is also called coagulable lymph. The white of eggs consists almost entirely of albumen.—Animal oil, generally solid at the temperature of the atmosphere, contains more oxygen and sebatic acid, than the vegetable oils. Among animal oils may be ranked fat, tallow, lard, suet, butter, &c. Fish oil is generally more liquid than other animal oils. Spermaceti is an animal oil, found in the head of a species of whale.—Bones consist chiefly of phosphate of lime, with carbonate of lime, and gelatine.—Blood consists of albumen, fibrin, colouring matter, and a mild oil. The colouring matter has been supposed to depend upon iron, but Vauquelin has proved, that the most delicate test could not evince the existence of iron in it. Blood, when suffered to rest, separates into two parts, the one, a coagulum or clot, called the crassamentum; the other, a fluid, called the serum.—Milk, if suffered to rest, throws upon its surface a butteraceous oil, called cream. If the remaining skimmed-milk be suffered to stand, it becomes sour, and separates into two parts: curd, which is chiefly albumen; and whey, (which is generally analogous to serum,) mixed with sugar and lactic acid.—Horn, &c. Nails, horns, hoofs, and quills, resemble coagulated albumen. Bile, urine, saliva, &c. are all animal substances of a complicated nature.

**ANIMAL Putrefaction**. Every animal body, when deprived of life, and exposed to the air, undergoes a decomposition, or resolution of its parts. Its colour becomes pale, and then changes to blue and green; the parts become soft, and send out a putrid smell, from the discharge of noxious gas. The organization is destroyed, the constituent parts of the animal substances form new arrangements, and are chiefly resolved into a gaseous state; and what remains is a dry powder, composed of earths and charcoal.

**ANIMALCULES**, such animals as are clearly discernible only by means of microscopes, for millions of millions of them might be contained in a thimbleful of water, which is the best element for studying their motions. By the microscope many kinds of animalcules have been discovered, as different from each other as the horse from the mouse; some indeed so exceedingly minute, that a million would not equal in magnitude a large grain of sand; and, as more and smaller objects have ever been discovered, in proportion to the goodness of the glasses with which they have been viewed, it is highly probable that there are numberless other species, of a size much less than those already discovered. Every drop of water, and almost any fluid, except oils and ardent spirits, either does or will, by standing exposed a few days in warm weather, swarm with living creatures. Some seem natural inhabitants of the fluids in which they are found; others live there only occasionally, in the manner of gnats, which, from eggs dropped in water by their parents, become swimming animals; but, after a short time, shed their skins, appear in a form without resem-

blance to that before assumed, take wing, and claim kindred with the countless millions which rejoice in the air. The largest sort are thin and transparent; they turn frequently, have many feet, often seen about the extremities; at one end are some bristles longer than the feet, resembling a tail. Their motion is swift, and their frequent turns and sudden stops would intimate that they were hunting after their prey, probably insects indefinitely smaller than themselves, that have hitherto escaped notice with the best glasses. They employ their feet in both running and swimming; for, putting a hair among them, like rope-dancers, they often creep along it, bending in odd postures. The second kind are spiral or screw-like: when they lie still, they often thrust forth a fringed or bearded tongue; a small current may be discerned towards them, probably caused by the nimble motion of some fins or legs, too minute to be discerned. Another sort, about the same size, but without tails, resemble a flounder: their feet may be seen clearly, as the water evaporates, when they move very nimbly. The next kind appear like slender worms, about fifty times longer than broad; their waving progressive motion is equal and slow. They swim with equal facility any way; and being every where of the same thickness, it is difficult to ascertain the head. A fifth sort are so small, that an hundred in a row would not equal the diameter of a grain of sand; and consequently a million are but equal in bulk to one such particle; their shape is nearly globular. A sixth kind have also been discerned, about the thickness of the last, but twice as long. The smallest drop of sulphuric acid, only as much as will stick to the point of a pin, put among these animalcules, will cause them all to fall down dead. So eels in paste are very entertaining objects when examined by any microscope, particularly the solar one, which very plainly distinguishes the motions of their intestines; and, when the water is nearly evaporated, and they are near expiring, their mouths appear opened to a considerable width. Leeuwenhoek says, no living creatures appear in rain water fresh descended, but after standing a few days, innumerable animalcules of different species, many thousand times smaller than a grain of sand, are visible by the microscope. In summer, the water in ditches appears sometimes greenish or reddish; which, examined with the microscope, is owing entirely to the millions of animalcules crowded on the surface. Their bodies are oval and transparent, the middle parts either green or red; seem composed of globules, so similar to the roe of fish, that it is believed to be the same, especially as they are found, after some time, perfectly clear and colourless, when they may be supposed to shed their spawn. The water from dunghills is so thronged with animalcules, that it seems all alive, and must be diluted before they can be separated to distinguish their kinds.

**ANNEALING**, **NEALING**, the cooling of bottles and glass gradually by placing the materials thus blown in a furnace, in which they gradually cool. By the process of annealing, the glass is kept for some time in a state approaching to fluidity; the heat increases the bulk of the crystallized part, and renders it so soft, that the internal parts have an opportunity of expanding, and forming a regular crystallization. A similar process is now used for rendering kettles, and other vessels of cast iron, less brittle. And as iron diminishes in bulk when it passes into a fluid state, the crystals of cast iron are destroyed by the blast of an air furnace, and the mass converted into forged iron, the particles of which it is composed having arranged themselves into that form of crystals or laminæ, by which forged iron is distinguished. See **IRON**, &c.

**ANNO DOMINI**, the year of our Lord; the computation of time from our Saviour's birth.

**ANNUAL**, in Astronomy, any thing which relates to the year, or which returns yearly; as *Annual Motion of the Earth*, *Argument of Longitude*, *Epacts*, *Equation*, &c.

**ANNUITIES**, signify any interest of money, rents, or pensions, payable from time to time, at particular periods. The most general division of annuities is into annuities certain, and contingent annuities; the payment of the latter depending upon some contingency; such, in particular, as the continuance of life. Annuities have also been divided into annuities in possession, and annuities in reversion; the former meaning such as have commenced, or are to commence immediately;

and the latter, such as will not commence till some particular future event has happened, or till some given period of time has expired. Annuities may be farther considered as being payable yearly, half-yearly, or quarterly. The present value of an annuity is that sum, which, being improved at compound interest, will be sufficient to pay the annuity. To find the present value of an annuity by the following TABLE, we have only to find the amount for £1 at the given rate of interest, and for the given time; which multiplied by the given annuity, or payment, will be the present worth.—*Example.* What is the present value of an annuity of £40 per annum, to continue 20 years, at the rate of 4 per cent.? By the Table, the amount of £1 for 20 years, at 4 per cent. is 13.590326; therefore,  $13.590326 \times 40 = £543.12s.$  very nearly.

TABLE.—The present Value of £1 per Annum, and from 1 to 60 years, at any rate of Compound Interest from 3 to 6 per Cent.

| Yrs. | At 3 per Cent. | 3½ per Cent. | 4 per Cent. | 4½ per Cent. | 5 per Cent. | 6 per Cent. |
|------|----------------|--------------|-------------|--------------|-------------|-------------|
| 1    | .970874        | .966184      | .961538     | .956938      | .952381     | .943396     |
| 2    | 1.913470       | 1.899694     | 1.086095    | 1.872668     | 1.859410    | 1.833393    |

ANNULET, a small square member in the Doric capital, under the quarter round.

ANODYNE, a medicine which eases pain, and procures sleep; as paregorics, which assuage pain; hypnotics, which procure sleep; and narcotics, which relieve by causing stupefaction.

ANOMALISTICAL YEAR, the period in which the earth passes through her orbit. The periodical year.

ANOMALY, in Astronomy, an irregularity in the planets, whereby they deviate from the aphelion, or apogee.

ANONA, the custard apple, cultivated in tropical climates on account of its fruit.

ANONYMOUS, in Law, the sending letters without signature, which is felony by the Black Act.

ANSÆ, the parts of Saturn's ring projecting beyond the disc.—ANSER, 2 small star in the milky way, between the Swan and Eagle.

ANTARES, a star of the first magnitude, *Cor Scorpionis*.

ANTECEDENT, in Mathematics, the first of two terms of a ratio.

ANTECEDENCE, in Astronomy, an apparent motion of a planet towards the west, or contrary to the order of the signs.

ANTESTATURE, in Fortification, a small retrenchment made of palisades, or sacks of earth, with a view to dispute with an enemy the remainder of a piece of ground.

ANTHELIX, the inward protuberance of the external ear, being a semicircle within, and almost parallel to the helix.

ANTHELMINTICS, medicines that destroy worms.

ANTHEMIS, camomile, medicinally aperient, carminative, emollient, and in some measure anodyne: the flowers afford a shining yellow.

ANTHERA, that part of the stamina within the corolla, that contains the pollen, which, when mature, it emits for the impregnation of the plant.

ANTHERICUM, spider wort.—ANTHOCEROS, horn flower.—ANTHOLYZA, mad flower.—ANTHOSPERMUM, amber tree.—ANTHOXANTHUM, vernal grass.

ANTHROPOPHAGI, men-eaters, which have existed in all ages, and in many countries, where neither religion nor philosophy enlighten the savage mind.

ANTHYLLIS, kidney vetch.

ANTIDESMA, Chinese laurel.

ANTIBILIOUS PILLS; aloes, scammony, Turkey rhubarb, and tartarized antimony; one grain of each makes one pill.

ANTIMONY, a mineral, so brittle as to be easily pulverized: it is of a whitish blue colour, is rarely found native, but generally combined with sulphur. Among the ancients it was in much repute as a dye for the eyelashes and eyebrows. As a medicine, it forms an emetic, when dissolved in wine and acetic acid. The tartaric acid forms with it tartar-emetic. In the arts, it is used to give the composition of burning mirrors a finer texture: it renders the sound of bell-metal more clear; mingled with tin, it makes this last harder, whiter, and sonorous; mixed with lead, it makes printing types smooth and firm; it purifies gold; and is employed in casting cannon balls.—For the brute creation, the virtues of antimony are highly extolled: it cures the measles in pigs, and purifies their blood: horses that have running heels are healed by it, by mixing one drachm of antimony with every feeding of oats you give the horse in the morning. When horses refuse it in oats, give it them in balls. Horses that look lean and scabby are soon fattened by a slight dose for two months every morning; and pigs also are fattened a fortnight sooner by having a few doses of antimony administered to them.

ANTINOUS, in Astronomy, a figure inserted into the constellation Aquila, the Eagle.

ANTIPODES, those inhabitants of the globe that live diametrically opposite to each other.

ANTIRRHINUM, snap-dragon, or calve's snout, which is recommended in leprosy, scrofulous, and hydropic cases.

ANTISCORBUTICS, medicines good against the scurvy.

ANTISEPTICS, such substances as resist putrefaction; as sea salt, nitre, salt of wormwood, alum, myrrh, asafoetida, terra japonica, aloes; Jesuits' bark, camomile, pepper, ginger, saffron, sage, rhubarb; valerian, mint, angelica, ivy, green tea, horse-radish, &c.; all the vegetable substances being dried.

ANTITHESIS, in Rhetoric, a contrast or opposition of

words or sentiments; and generally the favourites of young writers.

**ANTONOMASIA** is another figure of speech, in which, for a proper name, is put the name of some dignity, office, profession, &c.; as the king, or his majesty.

**ANTLIA PNEUMATICA**, the Pneumatic Pump, is a novel asterism, which De la Caille formed out of a few stars between Hydra and Argo Navis.

**ANVIL**, a smith's utensil, upon which he hammers his metal; at one end is sometimes a spike or horn, and the surface must be very smooth and flat, and so hard that a file can make no impression on it: it is mounted on a block, the stump or root of a tree. There are small anvils used by locksmiths, which stand on their benches, &c.

**AORTA**, the artery which rises immediately from the left ventricle of the heart, and is from thence distributed to all parts of the body, by two grand trunks ascending and descending.

**ANXIETY**, is a disagreeable sensation, quite different from pain, as being more obtuse, and less capable of being referred to any particular part, though frequently more intolerable than any pain. But we must take care to distinguish between anxiety in a medical sense, and that which is spoken of in common discourse. The latter does not at all depend on the state of the body, but belongs entirely to the mind; and arises from a sense of danger, or a foresight to any misfortune. The former is truly corporeal; and derives, no less than pain, its origin from a certain state of the body. Notwithstanding this difference, however, it is very possible for both these kinds of anxiety to be present at the same time, or for the one to be the cause of the other. A very great bodily anxiety will strike fear and despondency into the most resolute mind; and mental anxiety, on the contrary, if very violent and long-continued, may induce the former, by destroying the powers of the body, especially those which promote the circulation of the blood. Anxiety, in the medical sense of the word, arises in the first place from every cause disturbing or impeding the motion of the blood through the heart and large vessels near it; from diseases of the heart and its vessels, such as its enlargement, too great constriction, ossification, polypus, palpitation, syncope, inflammation, debility, and also some affections of the mind. It is likewise produced by every difficulty of breathing, from whatever cause it may arise; because then the blood passes less freely through the lungs: anxiety of this kind is felt deep in the breast. It is said also to arise from the difficult passage of the blood through the liver or other abdominal viscera. A certain kind of anxiety is very common and troublesome to hypochondriacal people; and arises from the stomach and intestines being either loaded with indigested and corrupted food, or distended with air produced by fermentation, and extricated from the aliments. By such a load or distention, the stomach, which is a very delicate organ, becomes greatly affected. Besides, the free descent of the diaphragm is thus hindered, and respiration obstructed. Anxiety of this kind is usually very much and suddenly relieved by the expulsion of the air; by which, as well as by other signs of a bad digestion, it is easily known. In these cases the anxiety is usually, though with little accuracy, referred to the stomach. Anxiety also frequently accompanies fevers of every kind, sometimes in a greater and sometimes in a lesser degree; arising as well from the general debility as from the blood being driven from the surface of the body, and accumulated in the large vessels: as in the beginning of an intermittent fever. Or it may arise from an affection of the stomach, when overloaded with crude, corrupted aliment, or distended and nauseated with too much medicated drink. As the fever increases the anxiety of the patient becomes greater and greater; remarkably so, according to the testimony of physicians, either immediately before the crisis, or on the night preceding it; as before the breaking out of exanthemata, hæmorrhagy, sweat, or diarrhoea, which sometimes remove fevers. The patient feels likewise an anxiety, from the striking in of any eruption or critical metastasis. This sensation also accompanies fevers and most other diseases, when the vital power is exhausted, and death approaches, of which it is the forerunner and the sign. It happens at that time, because the vital powers, unable to perform their functions, cannot make the blood cir-

culate. But what kind of anxiety this is, the other signs of approaching death shew very evidently. Moreover, even in the time of sleep, anxiety may arise from the same causes: hence frightful dreams, which frequently disturb our repose with surprise and terror.

**APAUMEE**, in Heraldry, a hand extended, the palm open, the fingers and thumb extended.

**APEPOIA**, INDIGESTION, which may be produced by abstinence and excess. Columbo root infused in a teapot with boiling water, and drank when cold in the forenoon, a wine-glass full at a time, is a very excellent dose when the stomach is languid. It is prescribed in substance with any grateful aromatic, or infused in Madeira wine, now and then interposing gentle doses of tincture of rhubarb.

**APERIENTS**, facilitate the circulation, and remove obstructions; smallage, fennel, asparagus, butcher's broom, and parsley, are the common aperients of the shops.

**APHANE**, parsley root.

**APHANIA**, a total loss of voice, mostly the effect of other disorders, and must be removed by eradicating the disease which had caused it.

**APHELIUM**, that point of a planet's orbit, in which it is farthest distant from the sun.

**APHIS**, the vinefretter, or plant louse, of which there are thirty-three species, all of them destructive to plants.

**APHTHÆ**, small round ulcers in the mouth.

**APHYLLANTHES**, leafless flower. Blue Montpellier pink.

**APIARY**, a place where bees are kept. See BEE.

**APIUM**, parsley, which should be used sparingly, for it is liable to produce epilepsy in some constitutions.

**APOGEE**, that part of the earth's orbit which is farthest from the sun. The sun's apogee and the earth's aphelion are one and the same point.

**APOGOGICAL DEMONSTRATION**; See ABSURD; an indirect way of proof, by observing the absurdity of the contrary.

**APOPHYGE**, a concave ring of a column, above or below a flat member.

**APOPLEXY**, a disease by which the patient is suddenly deprived of all his senses, and of voluntary motion

**APOSCYNUM**, dog's-bane.

**A POSTERIORI DEMONSTRATION**, proves or disproves the fact from the enumeration of particulars, as when we infer the rotundity of the earth from the circular shadow it casts on the moon.

**APOSTLES' CREED**, a formula of the Christian faith, occurs first in the writings of St. Ambrose; and was introduced into the church about the end of the 5th century, when Petrus Gnapheus prescribed the recital of it every time divine service was performed.

**APOSTROPHE**, in Rhetoric, a figure by which a person, who is either absent or dead, is addressed as if he were present, and listening to us.

**APOTHECARY**, one who practises the art of pharmacy; in London, the apothecaries are one of the city companies; and they are obliged to make up their medicines according to rules laid down in the college dispensatory. Their hall, in Blackfriars, is the first laboratory in the universe.

**APOTHEOSIS**, the absurd ceremony of making a mortal a god. A gem in the museum of Brandenburg, represents the apotheosis of Julius Cæsar, mounted upon a celestial globe, and holding a helm in his hand, as if he were now the governor of heaven, as before of the earth.

**APOTOME**, in Geometry, the difference between two immeasurable lines. In Music, the difference between a greater and lesser semitone; expressed by the ratio 128:125.

**APPARATUS**, the appendages or utensils belonging to machines; as the apparatus of an air-pump, electrical machine, &c.; meaning the various detached parts which are necessary for putting the machinery in action, and for performing experiments, &c.

**APPARENT**, in Mathematics and Astronomy, is used to signify things as they appear to us, in contradistinction from real or true; and in this respect the apparent state of things is often very different from their real state: as is this case of distance, magnitude, &c.

**APPARENT Conjunctions of the Planets**, is when a right line

supposed to be drawn through their centres, passes through the eye of the spectator, and not through the centre of the earth.—And, in general, the apparent conjunction of any objects, is when they appear or are placed in the same right line with the eye.

**APPARENT Diameter of an Object**, is the angle that it subtends at the eye, which diminishes as the distance increases; so that a small object at a small distance may have the same apparent diameter as a much larger object at a greater distance, provided they subtend the same or equal angles at the eye. If the objects are parallel to each other, their real diameters are, in this case, proportional to their distances. The apparent diameter also varies with the position of the object; and of equal objects at equal distances, those which stand in a position most nearly perpendicular to the line of their direction from the observer, will appear to have the greatest diameter; our idea of the apparent magnitude generally varying nearly as the optic angle. But although the optic angle be the usual or sensible measure of the apparent magnitude of an object, yet habit, and the frequent experience of looking at distant objects, by which we know that they are larger than they appear, has so far prevailed upon the imagination and judgment, as to cause this likewise to have some share in our estimation of apparent magnitudes; so that these will be judged to be more than in the ratio of the optic angles.

**APPARENT Altitude of Celestial Objects**, is effected chiefly by refraction and parallax; and that of terrestrial objects, by refraction.

**APPARENT Figure**, the figure or shape which an object appears under when viewed at a distance; and is often different from the true figure. Thus a straight line, viewed at a distance, may appear but as a point; a surface, as a line; and a solid, as a surface. Also these may appear of different magnitudes, and the surface and solid of different figures, according to their situation with respect to the eye: thus the arch of a circle may appear a straight line; a square, a trapezium, or even a triangle; a circle, an ellipsis; angular magnitudes, round; and a sphere, a circle. Also all objects have a tendency to roundness and smoothness, or appear less angular, as their distance is greater: for, as the distance is increased, the smaller angles and asperities first disappear, by subtending a less angle than one minute; after these, the next larger disappear, for the same reason; and so on continually, as the distance is more and more increased; the object seeming still more and more round and smooth. So, a triangle, or square, at a great distance, appears only as a round speck; and the edge of the moon appears round to the eye, notwithstanding the hills and valleys on her surface. And hence it is also, that near objects, as a range of lamps, and such like, seen at a great distance, appear to be contiguous, and to form one uniform continued magnitude, by the intervals between them disappearing, from the smallness of the angles which they subtend.

**APPARENT Motion**, is either that motion which we perceive in a distant body that moves, the eye at the same time being either in motion or at rest; or that motion which an object at rest seems to have, while the eye itself only is in motion. The motions of bodies at a great distance, though really moving equally, or passing over equal spaces in equal times, may appear to be very unequal and irregular to the eye, which can only judge of them by the mutation of the angle at the eye. And motions, to be equally visible, or appear equal, must be directly proportional to the distances of the objects moving. Again, very swift motions, as those of the luminaries, may not appear to be any motions at all, but like that of the hour-hand of a clock, on account of the great distance of the objects: and this will always happen, when the space actually passed over in one second of time, is less than about the 14000th part of its distance from the eye; for the hour-hand of a clock, and the stars about the earth, move at the rate of fifteen seconds of a degree in one second of time, which is only the 13751 part of the radius or distance from the eye. On the other hand, it is possible for the motion of a body to be so swift, as not to appear any motion at all; as when, through the whole space it describes, there constantly appears a continued surface or solid as it were generated by the motion of the object, as is the

case when any thing is whirled very swiftly round, describing a ring, &c. Also, the more oblique the eye is to the line which a distant body moves in, the more will the apparent motion differ from the true one. So, if a body revolve with an equable motion in the circumference of the circle *A B C D*, &c. and the eye be at *E* in the plane of the circle; as the body moves from *A* to *B* and *C*, it seems to move slower and slower along the line *A L K*, till, when the body arrives at *C*, it appears at rest at *K*; then, while it really moves from *C* by *D* to *F*, it appears to move quicker and quicker from *K* by *L* to *A*, where its motion is quickest of all; after this it appears to move slower and slower from *A* to *N*, while the body moves from *F* to *H*: there becoming stationary again, it appears to return from *N* to *A* in the straight line, while it really moves from *H* by *I* to *A* in the circle. And thus it appears to move in the line *KN* by a motion continually varying between the least, or nothing, at the extremes *K* and *N*, and the greatest of all, at the middle point *A*. Or, if the motion be referred to the concave side of the circle, instead of the line *KN*, the appearances will be the same. All this is manifestly referable to the motions, stations, retrogradations, &c. of the planets. If an eye move directly forwards in one direction, any remote object at rest will appear to move in a parallel line the contrary way. But if the object move the same way, and with equal velocity, it will seem to be at rest. If it move the same way, with less velocity, it will appear to move backwards, with the difference of the velocities: if it move with greater velocity, it will appear to move forwards with the difference of the velocities. And when the object has a real motion contrary to that of the eye, it appears to move backwards with the sum of the velocities. The truth of all this is experienced by persons in a boat moving on water, or in a moving carriage, making observations on distant objects in motion, or at rest.

**APPARENT Place of an Object**, in Optics, is that in which it appears, when seen in or through glass, water, or other reflecting or refracting media. In most cases, it differs much from the true place.

**APPARENT Station**, in Astronomy, the position or appearance of a planet, or comet, in the same point of the zodiac for several days.

**APPARENT Heir**, in Law, he whose right is indefeasible, provided he outlives the ancestor; as the eldest son, or his issue. **HEIRS Presumptive**, are those whose right of inheritance may be defeated by the contingency of some nearer heir being born. Thus, a second son or nephew may be heir presumptive, but his right of inheritance may be defeated by the birth of a child to his elder brother or uncle; or a daughter may be heir presumptive, as her hopes may hereafter be cut off by the birth of a son, who, by the English law, succeeds to both title and inheritance.

**APPARITION**, in Astronomy, denotes a star or other luminary's becoming visible, which before was hid: in which sense it stands opposed to Occultation. Thus the heliacal rising is rather an apparition than a proper rising.

**APPEAL**, in Law, the removal of a cause from an inferior to a superior judge; as from the ordinary courts to the House of Lords.

**APPEARANCE**, in Perspective, is the representation or projection of a figure, or body, upon the perspective plane. **Direct APPEARANCE**, in Optics, is the view or sight of an object by direct rays, without either refraction or reflection. In Astronomy, appearances are more commonly termed phenomena and phases.

**APPLE**. There are many kinds of apples; the golden pippin, which, though small, keeps well, and the tree grows well in good light soil; the Olsin pippin, or Arbroath, as to flavour, is outdone by none but the nonpareil; the Ribston pippin will keep till apples come again, and the tree grows in any situation; the golden and royal russets are handsome apples, but

the nonpareil is the chief of the russets; the codlings grow freely, but none of them keep; the golden russet is a summer apple; the royal pearmain is large and beautiful.

**APPLE Sauce for a Goose.** Pare, core, and slice your apples, put them in a saucepan with as much water as will keep them from burning; set them over a very slow fire. Keep them close covered till they are all of a pulp, then put in a lump of butter and sugar to your taste. Beat them well, and send them to table in a china-bason or sauce-boat, with a proper ladle.

**APPLICATE: Ordinate** APPLICATE, in Geometry, is a right line drawn across a curve, so as to be bisected by the diameter of it; being what we commonly call double ordinate.

**APPLICATION OF GEOMETRY TO ALGEBRA**, is the converse of the first of the two succeeding cases; for as in that, algebra is employed in order to obtain the solution of a geometrical problem, so in this case geometry is made use of to obtain the solution of an algebraical problem. This relates principally to the finding the roots of an equation by a geometrical construction, which is explained under the article CONSTRUCTION.

**APPLICATION OF Algebra and Geometry to Mechanics**, consists principally in representing, by equations, the curves described by bodies in motion; as in the theory of Projectiles, &c.

**APPLICATION OF Geometry and Astronomy to Geography**, principally consists in determining by geometrical and astronomical operations, the figure of the terrestrial globe; in finding the positions of places by their observed latitude and longitude; and in determining, by geometrical operations, the positions of places that are not very remote from one another. Astronomy and geography are again applicable to the theory of navigation.

**APPRENTICE**, one who is bound by covenant to serve a master, upon condition that he instructs or causes him to be instructed in his profession, art, or trade. Seven years is deemed the legal period; but from this there are many deviations. Several acts of parliament specify the obligations of masters and apprentices. The duties paid on indentures and premiums may be gathered from the enactments by which they are regulated.

**APPROACH**, in Fortification, the works thrown up by the besiegers in order to get near a fortress without being exposed to the enemy's cannon. In Gardening, it signifies the inoculating or ingrafting the sprig of one tree with another, without cutting it off the parent tree.

**APPROXIMATION**, in Algebra and Arithmetic, is the method of approaching nearer and nearer to the quantity sought, when there is no method of obtaining the exact value: this is the case in all rules for finding the square or cube root of any number that is not an exact square or cube.

**APRICOT**: of this fruit we have several kinds; as, the more-park, or peach apricot, is a large handsome fruit, by many persons thought the richest of our stone fruits; the orange apricot grows freely, and is excellent for preserving; the Breda is juicy; the Brussels, juicy and high flavoured; the masculine, though small and sharp flavoured, is the earliest apricot we cultivate.

**APRIL**, the fourth month of the year, according to the common, but the second according to the astronomical computation. It contains 30 days. In this month the sun travels through the sign Taurus; or more properly, the earth is now in Scorpio, and the sun, as seen from the earth, appears in Taurus.

*The APRIL Calendar*, in animated nature, exhibits the viper and woodlouse; the mistletoe thrush pairs; frogs croak and spawn; and moths appear in the first week. In the second, the stone curlew clamours, young frogs appear, pheasant cocks crow, trouts rise, and spiders creep plentifully. In the third week, the crested wren sings; blackbirds, ravens, pigeons, hens, and ducks, sit. In the fourth, the feldfare leaves us, and the swallow returns; the nightingale sings, the bittern makes a noise; the house-martin skims the air, the blackcap whistles, and the common snake creeps abroad.—In vegetable nature, various shrubs and trees blossom, with the daffodil, hyacinth, wallflower, cowslip, periwinkle, ground ivy, beech and elm trees; and the larch shoots its wiry leaves. Nursery men now sow for fruit-trees, forests and woods, and all sorts of profitable plantations in masses; those evergreens, the pine, fir, cedar of Lebanon, holly, and yew, are planted; and all the operations of

routine culture, as hoeing, road-making, draining, cropping and fencing, are performed. The gardener grafts his fruit-trees; plants cuttings of gooseberry and currant shrubs; and transplants evergreens. The flower garden is cropped, slips and offsets are propagated, insects are destroyed, and the routine culture proceeds by weeding, hoeing, &c. Pleasure grounds and shrubberies are now finished planting; lawns are formed and repaired; the fires of the green-house are discontinued. In the kitchen garden, artichokes are dressed and planted; asparagus beds are dug and forked, or sown; beans are planted and couched up; beet, brocoli, Brussels sprouts, cap-sicums, carrots, leeks, celery, onions, peas, savoys, skirret, turnips, and salads, are sown; cabbages, cauliflower, German greens, potatoes, and seacale are planted. The cherry-house is forced; the grapery is strictly attended to, established plants are forced in it; the forcing peach house, and the pinery and hot beds require all the gardener's care.

*Correct List of every thing in Season in April.*—Meat. Beef, mutton, veal, lamb.—Fish. Carp, chub, tench, trout, crawfish, salmon, turbot, soles, skate, mullets, smelts, herrings, crabs, lobsters, prawns.—Poultry, &c. Pullets, fowls, chickens, ducklings, pigeons, rabbits, leverets.—Roots, &c. Coleworts, sprouts, brocoli, spinage, fennel, parsley, chervil, young onions, celery, endive, sorrel, burnet, tarragon, radishes, lettuces, all sorts of small salad, thyme, and all sorts of pot-herbs.—Fruit. Oranges, lemons, forced cherries, apricots for tarts, grapes.

**A PRIORI**, (*demonstration à priori*), proves or disproves the fact from the law, or the effect from the cause; as when we deduce the immortality of the soul from the fact, that the soul is a thinking principle, and that therefore it is immaterial and indestructible.

**APRON**, in naval Architecture, a piece of curved timber fixed behind the lower part of the stern, and immediately above the foremost end of the keel. In Gunnery, the piece of lead that covers the touch-hole of a gun.

**APTERA**, the seventh order of insects, and such as have no wings.

**APUS INDICA**, the Bird of Paradise, a small asterism placed near the South Pole, contains eleven stars, none of which exceed the 4th magnitude.

**AQUARIUS**, the 11th sign of the zodiac, through which the sun moves in the month of January. Aquarius is the Egyptian Canopus or Neptune, with his pitcher. Towards the end of July Aquarius sets with his head foremost, when the Egyptians fable, that he made the river Nile overflow by plunging his pitcher into it! This constellation is bounded on the north by Equuleus and Pegasus, east by Pisces and Cetus, south by Piscis Australis and Apparatus Sculptoris, and west by Capricornus and Antinous. There are 108 stars in this sign, four of which are of the 3d magnitude, six of the 4th, &c. The chief star  $\alpha$ , of the 3d magnitude, having  $1^{\circ} 11' 22''$  south declination, and  $329^{\circ} 7' 43''$  right ascension, rises at London, on the east point of the horizon, and its rising and culminating on the first day of each month, are expressed in the following Table: Meridian Altitude  $37^{\circ} 17' 38''$ .

| MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. | MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. |

**AQUA-TINTA ENGRAVING.** By aqua-tinta engraving we can produce prints resembling drawings in Indian-ink. The principle of the process consists in corroding the copper with aqua fortis, so that an impression from it has the appearance of a tint of ink laid on the paper. This is done by covering the copper with a powder or some substance which takes a granulated form, so as to prevent the aqua fortis from acting where the particles adhere, and by this means causes it to corrode the copper partially, and in the interstices only. When these particles have been extremely minute, the impression from the plate appears like a wash of Indian-ink; but when they are large, the granulation is more distinct, and as this may be

varied at pleasure, it may be adapted as successfully to a variety of purposes and subjects. This powder, or granulation, is called *aqua-tinta grain*; there are two methods of producing it. Having etched the outline on a copper-plate, prepared in the usual way by the coppersmith, procure some substance finely powdered and sifted, which will melt with heat, and when cold will adhere to the plate, and resist the action of *aqua fortis*. The substances used for this purpose, either separately or mixed, are asphaltum, Burgundy-pitch, resin, gum-opal, gum-mastich; and all the resins and gum-resins answer the same purpose. Common resin has been generally used, and answers tolerably; though gum-opal makes a better grain to resist the *aqua fortis*. The substance intended to be used for the grain is distributed equally over the plate; different methods of performing this part of the operation have been used by different engravers. The usual way is to tie up the powder in a muslin bag, which is struck against a piece of stick, held at some height above the plate; the powder that issues out falls gently, and settles equally over the plate; as hair powder upon the furniture, after the operations of the barber. The plate being covered equally over with the dust or powder, the operator proceeds next to fix it upon the plate, by heating it gently, so as to melt the particles. This may be done by holding under the plate lighted pieces of rolled-up brown paper, moving them about till every part of the powder is melted; this will be known by its brownish change of colour. It is now to be suffered to cool, or be ready for the next part of the process. Such parts of the drawing to be engraved as are perfectly white, have their corresponding parts of the plate covered with turpentine varnish, diluted with turpentine to a proper consistence, to work freely with the pencil, and mixed with lamp-black to give it colour; if transparent, the touches of the pencil would not be distinctly seen. The margin of the plate, is also covered with varnish. When the varnish is dry, a border of wax is raised round the plate, as in etching, and you pour out the *aqua fortis* properly diluted with water. This is called *biting-in*. It is the part of the process most uncertain, and requiring the greatest degree of experience. When the *aqua fortis* has lain on so long that the plate, when printed, would produce the lightest tint in the drawing, it is poured off, and the plate washed with water, and dried. When dry, the lightest tints in the drawing are varnished again, and the *aqua fortis* poured on as before, and the same process is repeated as often as there are tints to be produced in the plate. Although many plates are etched entirely by this method of stopping-out and biting-in alternately, yet in general it is very difficult to stop round, and leave out all the finishing touches, as also the leaves of trees and other objects, which in this manner it is impossible to execute with freedom. To overcome this difficulty, another process has been invented, by which these touches are laid on the plate with as much ease and expedition as in an Indian-ink drawing. Fine washed whiting mixed with a little treacle or sugar, and diluted with water in the pencil, so as to work freely, is laid on the plate covered with the *aqua-tint* ground, in the same manner and on the same parts as ink on the drawing. When dry, the plate is varnished with a weak thin varnish of turpentine, asphaltum, or mastich: when dry, *aqua fortis* is poured on. The varnish immediately breaks up in the parts where the treacle mixture was laid, and exposes those places to the action of the acid, while the rest of the plate remains secure. The effect of this is, that all the places where the treacle was used, are bit-in deeper than the rest, and have all the precision and firmness of touches in Indian-ink. After the plate is completely bitten-in, the bordering wax is taken off, by heating the plate a little with a lighted piece of paper; it is then cleared from the ground and varnish by oil of turpentine, and wiped clean with a rag and a little fine whiting, when it is ready for the printer. The disadvantages of this method of *aqua-tinting* are, a difficulty to produce the required degree of coarseness or fineness in the grain, and plates so engraved print not many impressions before they are worn out, and though occasionally of service, it is therefore seldom used. The second method of producing the *aqua-tint* ground, generally practised, is the following. Some resinous substance, as common resin, Burgundy-pitch, or mastich, dissolved in spirits of wine, is poured all over the

plate, held in a slanting direction that the superfluous fluid may drain off; it is then laid down to dry. The spirit, in evaporating, leaves the resin in a granulated state, or rather, the latter has cracked in every direction, still adhering firmly to the copper. A grain is thus produced with great ease, extremely regular and beautiful, and, in comparison of the former method, much superior for most purposes. After the grain is formed, every part of the process is conducted as described above. There are some particulars necessary to be known, to secure success in the operation. The spirits of wine used for the solution must be of the best quality, highly rectified. That sold in shops generally contains camphor, which entirely spoils the grain. Rosin, Burgundy-pitch, and gum-mastich, when dissolved in spirits of wine, produce grains of a different appearance and figure, and are sometimes used separately, and sometimes mixed in different proportions, according to the taste of the artist, some using one substance and some another. To produce a coarser or finer grain, it is necessary to use a greater or smaller quantity of resin; and to ascertain the proportions, the liquor may be poured on several spare pieces of copper, and the grain examined, before it is applied to the plate to be engraved. When the solution is made, it must stand still and undisturbed for a day or two, till all the impurities of the rosin have settled to the bottom, and the fluid is quite pellucid. No other method of freeing it from those impurities has been found to answer: straining it through linen or muslin fills it with hairs, which ruin the grain. The room in which the liquid is poured on the plate must be perfectly still, and free from dust, which whenever it falls on the plate while wet, causes a white spot, which it is impossible to remove without laying the grain afresh. The plate must also be previously cleaned carefully with a rag and whiting, as the smallest stain or particle of grease produces blemish in the grain. All these attentions are necessary, to produce regular grain; and, after every thing that can be done by the most experienced artists, there is still much uncertainty in the process. Artists are some times obliged to lay on the grains several times before they procure one sufficiently regular. The same proportions of materials do not always produce the same effect, which depends greatly on their qualities; and it is even materially altered by the weather. These difficulties are not surmounted but by experience; and those who daily practise the art, are liable to unforeseen accidents. It is to be lamented, that so elegant and useful a process should be so extremely delicate and uncertain. As the plate is held in a slanting direction, to drain off the superfluous fluid, there will naturally be a greater body of the liquid at the bottom than the top of the plate. Hence, a grain laid in this way is always coarser at the lowermost side of the plate. The most usual way is, to keep the coarsest side for the foreground, that being generally the part which has the deepest shadows. In large landscapes, various parts are sometimes laid with different grains, according to the nature of the subject. The finer the grain is, the more the impression resembles Indian-ink, and the fitter it is for imitating drawings: but fine grains are apt to come off before the *aqua fortis* has lain on long enough to produce the desired depth; and as the plate is not corroded so deep, it sooner wears out in printing: coarser grains, on the contrary, are firmer, the acid goes deeper, and the plate throws off a greater number of impressions. This is evident when we consider, that, in the fine grains, the particles being small are near each other, and consequently the *aqua fortis*, which acts laterally as well as downwards, soon undermines the particles, and causes them to come off. If left too long on the plate, the acid would eat away the grain entirely. The moderately coarse grains are on these accounts more sought after, and answer better than the fine grains formerly in use. Though there are difficulties in laying properly the *aqua-tint* grain, yet corroding the copper, or biting-in, so as to produce exactly the tint required, is even more precarious and uncertain. No rules can be laid down, by which success in this process can be secured; a deal of experience and attentive observation alone enable artists to do it with certainty. We will therefore give some hints which may be of importance to those who wish to obtain the practice of this art. The longer the acid remains in the copper, the deeper it bites, and consequently the darker

the shade on the impression. It may be of some use, therefore, to have several bits of copper laid with aqua-tint grounds, of the same kind to be used in the plate, and to let the aqua fortis remain for different lengths of time on each; and then to examine the tints produced in one, two, three, four minutes, or longer. Observations of this kind, frequently repeated, and with acid of various degrees of strength, will assist the judgment in guessing at the tint to be produced in the plate. A magnifier is also useful, to examine the grain, and observe the depth to which it is bit. No proof of the plate can be obtained till the whole process is finished. Therefore if any part appears bit too dark, it must be burnished down with a steel burnisher; but this requires delicacy and good management, not to make the shade streaky; and as the beauty and durability of the grain are usually injured by it, it should be avoided as much as possible. Those parts not dark enough, must have a fresh grain laid over them, and be stopped round with varnish, and subjected again to the aqua fortis. This re-biting requires care and attention. The plate must be well cleaned out with turpentine before laying on the grain, which should be pretty coarse, else it will not lay upon the heights only, as it is necessary to produce the same grain. If the new grain is different from the former, it will be rotten, not clear and fine.—In this general account of the process of engraving in aqua-tinta, we believe no material circumstance has been omitted, that can be communicated, without seeing the different stages of the operation: but after all, no written directions whatever can enable a person to practise any art perfectly, much less engraving in aqua-tinta. Its success depends upon so many niceties, an attention to circumstances apparently so trifling, that the person who attempts it, must not be surprised if he does not succeed at first. It is a species of engraving simple and expeditious, if every thing goes on well; but precarious, and liable to errors which are rectified with great difficulty. It seems adapted for imitation sketches, washed drawings, and slight subjects; but not at all calculated to produce prints from finished pictures. Nor does it appear suitable for book-plates, since it prints not a sufficient number of impressions. It cannot, therefore, be put in competition with the other modes of engraving; but, confined to subjects for which it is calculated, it is extremely useful, as it is expeditious, and may be executed with much less trouble than any other mode of engraving. But even this circumstance is a source of mischief. It occasions the production of a multitude of prints, that have no other effect than that of vitiating the public taste.

**AQUEDUCT**, a conduit of water, is a construction of stone and timber built on uneven ground, to preserve the level of

water, and to conduct it through canals from one place to another. Some of these aqueducts are visible, and others subterraneous: those of the former sort are constructed at a great height, across valleys and marshes, and supported by piers and ranges of arches; the latter are formed by piercing the mountains, and conducting them below the surface of the earth. They are built of brick, stone, &c. and covered above with vaulted roofs, or flat stones, serving to shelter the water from the sun and rain; and of these, some are double, and others triple, that is, supported by two or three ranges of arches. Of the latter kind, are the Pont-du-gard in Languedoc, supposed to have been built by the Romans to carry water to the city of Nismes; that of Constantinople; and that which, according to Procopius, was constructed by Cosroes, king of Persia, near Petra in Mingrelia, and which had three conduits in the same direction, each elevated above the other. Some of the aqueducts are paved, others convey the water through a natural channel of clay; and it was frequently conducted by pipes of lead into reservoirs of the same metal, or into troughs of hewn stone.

The **AQUEDUCT of Alcantara**, fig. 83, near Lisbon, is 56,380 feet long; supported on 127 arches, the middle arch being 220 feet high, and 108 feet wide; the other arches are extremely well executed; and in standing at the western angle, the eye ranges over the piers, without the slightest variations of any of them from the vertical plane. The joints are close, and the horizontal lines well preserved. The voussoirs of the arches appear of equal length, and their extrados are adapted to the courses of 16 inches deep. Those of the middle arch appear about 8 feet in length, and 15 of them constitute the depth of the work; but the four ranks of projecting stones, which probably carried the centering, hurt the uniformity. The only perceptible sinking occasioned by the earthquake is in the north parapet, and in one of the towers. A stream, or rather winter-torrent, runs through the channel under the great arch, and empties itself into the Tagus, about two miles distant. The width of the section at top is 30 feet one inch, and at bottom 25 feet 10 inches. The steepest or eastern bank is the Lisbon side, and the gently rising or western bank, the Bellas side; the spectator will then face the south. A statue of John V. who reigned in 1717, is represented in Roman costume on a pedestal on the eastern end, where the footpath commences, from which to the arch No. 1, is 570 feet seven inches solid wall. The most modern and most extensive aqueduct is that built by Louis XIV. near Maintenon, for carrying the river Bure to Versailles. It is 7000 fathoms long, and its elevation 2560 fathoms; and contains 242 arcades.

*Bridge of Alcantara.—Fig. 83.*

It is a very prevailing opinion, that the Romans, amidst all their magnificence, were ignorant of the simplest elements of hydrostatics, and therefore entirely unacquainted with the

method of conducting and raising water by a train of pipes. Nothing, however, can be worse founded than this notion. The ancient writers, who either treat of the subject, or incidentally

mention it, are clear and explicit in their remarks, while many vestiges of art still attest the accuracy of those statements. Pliny, the natural historian, lays down the main principle, that "water will invariably rise to the height of its source." *Subit altitudinem exortus sui*. He subjoins, that leaden pipes must be employed, to carry water up to an eminence. Palladius, in his treatise *De Re Rustica*, teaches how to find springs, by observing immediately, from the sunrise in the month of August, the vapours which hover above particular spots; and having there dug a well, he directs the water to be conducted to the farm or villa, either by a conduit constructed of masonry, or by means of pipes of lead, of wood, or even of earthenware. He allows one foot in sixty, or in a hundred, for an uniform descent. But if the ground should afterwards rise, he says, the conduit must be supported on piles or arches, or the water must be raised in leaden pipes, when it will mount just to the level of its head. But Palladius testifies his aversion to the use of lead, as apt to become covered with ceruss, and thereby rendered unwholesome, or even poisonous. This consideration had, no doubt, served to restrain the general adoption of leaden pipes among the Romans. Still, however, we may infer, from the allusions of the poets, that such pipes had come into very common use. They were not cast tubular as at present, but consisted of thin plates bent up into the form of a cylinder, and soldered along the edge. They must frequently have given way, therefore, at this seam. Horace asks, if the water which threatens in the streets to burst its lead, be purer than the rivulet that trembles and murmurs as it flows. *Epist. l. x. 20*. Ovid compares the gush of blood from the mortal wound which Pyramus, in the agony of despair, had inflicted upon himself, to the accidental rupture of a leaden pipe. *Metam. iv. 120*. Statius speaks, no doubt with poetical exaggeration, of whole rivers being discharged by such conduits. *Statius, l. Sylv.* Vitruvius describes the three principal modes of conveying water; but directs, as the previous operation, to trace a level (*libramentum*) on the ground. This libration was performed by the dioptron, the water-level, or the chorobates. The dioptron seems to have been a sort of quadrant fitted with sights; the water-level consisted of a tube, probably of copper, five feet long and an inch wide, turned up an inch and a half at both ends, and was adjusted till water rose equally in them; the chorobates, or perambulator, which he considered as the most accurate instrument, was composed of a rod twenty feet long, having a square and plummet attached at each extremity. Vitruvius allows only half a foot in the hundred, for the slope of an aqueduct. After the water had reached the walls of a city, it was admitted into a reservoir or castellum, divided into three distinct and equal compartments, one to feed the pools and fountains, another to supply the public baths, and a third for the accommodation of palaces and private houses. The distribution of the water was effected commonly by means of leaden pipes. The smallest of these was called a denaria, being ten feet in length, the sixteenth part of this in breadth, and weighing 120 Roman pounds. This gives, for the thickness of the lead, exactly the quarter of an English inch. In lower situations, where the stress against the sides was greater, the pipes appear to have been made proportionally stronger. The quantity of water delivered from the cisterns was regulated by the dimensions of the spouts, termed calices. These formed a series of twenty-five different kinds, which served as *moduli*. Their diameters were sometimes reckoned by ounces, or the twelfth parts of a Roman foot, but more commonly by quarter digits, or the sixty-fourth part of a foot. The quinaria seem to have been considered as the standard, and its width must have hence corresponded to the 906 part of an English inch. The ajutate or length of all those spouts was the same, being twelve digits, or three-fourths of a Roman foot, and therefore equal to 8.7 English inches. Prony conjectures, from very probable grounds, that such was also the altitude of a column of pressure above the middle of each orifice. This estimate gives 1979 cubic feet, for the quantity of discharge of a denaria, in the space of twenty-four hours. Leaden pipes were likewise employed to carry water across vales and over eminences. But it behoved to erect, at the several incurvations, columnaria, or chimneys, to give vent to the air which might collect and gorge up the passage of the

water. Such funnels required to be raised to near the height of the fountain head. Vitruvius, however, joins with Palladius and Columella, in recommending pipes of earthenware, as not only cheaper, but more wholesome, than those of lead. They could be formed thicker, if necessary, and might be farther strengthened and secured, they said, by an outer coating of lime worked up with oil. But such pipes not being glazed, it became necessary, before using them, to fill up the pores by a sort of puddling, that is, to wash their inside with favilla, or fine wood-ashes. No wonder, therefore, that the leaden pipes were held in little estimation among the ancient Romans. They seem to have been seldom used indeed beyond the limits of the imperial city, except as auxiliaries in the smaller aqueducts. When such conduits happened to be interrupted by a deep narrow vale, instead of joining them by an arch thrown over the gap, the connexion was sometimes formed by an inverted syphon of lead, carried on the one side down to the bottom, and brought up on the other. Rome was supplied by nine great aqueducts, according to Frontinus, who had been appointed curator of those magnificent works by the emperor Nerva. He added five more; and the number was afterwards augmented, by successive emperors, to twenty. Of these, the most remarkable were, 1. The Aqua Appia, thus named from its having been constructed by the censor Appius Claudius, in the 442d year of Rome, begun between the sixth and eighth milestone, made a circuit of 880 deep paces, and then proceeded by a deep subterranean drain of more than 11 miles, delivering the main body of its water in the Campus Martius. 2. The Old and New Anio, conduits so called from their bringing into Rome the waters of that river. The former began above the Tiber at the 30th milestone, and consisted mostly of a winding drain carried through an extent of about 43 miles. The latter, constructed under Nero, took a higher level, running 7543 paces above ground, and then pursuing a subterranean passage of 54,267 paces in length. 3. The Aqua Marcia, which owed its formation to Quintus Martius, rose from a spring, distant 33 miles from Rome, made a circuit of three miles, and afterwards, forming a vault of 16 feet diameter, it ran 38 miles along a series of arcades at the elevation of 70 feet. It had vents perforated at certain distances, for disgorging the collected air; and the conduit was occasionally interrupted by deep cisterns, in which the water settled and deposited its sediment. It was hence remarkable for its clear green colour. *Lib. xxx. 5*. The Aqua Julia and the Aqua Tepula were brought by the same aqueduct, only in two lower conduits. 4. The Aqua Virginea, conducted by Agrippa, the patriotic lieutenant of Augustus, who laboured to improve and beautify Rome; and who, according to Pliny, formed in one year 70 pools, 105 fountains, and 130 reservoirs. It commenced at a very copious spring, in the midst of a marsh, at the distance of eight miles from the city, and ran about 12 miles, passing through a tunnel of 800 paces in length. 5. The Aqua Claudia, begun by Nero, and completed by Claudius, took its rise 38 miles from Rome; it formed a subterranean stream  $36\frac{1}{4}$  miles in length, ran  $10\frac{3}{4}$  miles along the surface of the ground, was vaulted for the space of three miles, and supported on arcades through the extent of seven miles, being carried along so high a level as to supply all the hills of Rome. It was built of hewn stone, and still continues to furnish the modern city with water of the best quality, which has hence procured it the name of Acqua Felice. The practice of tunnelling was begun under Augustus, who greatly extended the aqueducts. Other emperors likewise directed their attention to that important object. Trajan shewed particular solicitude in improving the aqueducts. Those works were executed in the boldest manner; nothing could resist the skill and enterprise of the Romans; they drained whole lakes, drove mines through mountains, and raised up the level of valleys by accumulated arcades. The water was kept cool by covering it with vaults, which were often so spacious, that, according to Procopius, who wrote in the time of Belisarius, a man on horseback could ride through them. So abundant indeed was the supply, as to induce Strabo to say, that whole rivers flowed through the streets of Rome. Contemplating the utility, the extent and grandeur of those aqueducts, Pliny justly regarded them as the wonder of the world. *Plin. xxxvi. 15*. The same idea is

expressed by the poet Rutilius. *Rutilius in Iiin.* According to the enumeration of Frontinus, the nine earlier aqueducts delivered every day 14,018 quinaria. This corresponds to 27,743,100 cubic feet. We may therefore extend the supply, when all the aqueducts were in action, to the enormous quantity of 50,000,000 cubic feet of water. Reckoning the population of ancient Rome at a million, which it probably never exceeded, this would furnish no less than fifty cubic feet, for the daily consumption of each inhabitant. In modern Rome, three aqueducts, the Acqua Felice, Juliana, and Paulina, with some additional sources, deliver in twenty-four hours, according to the calculation of Prony, 5,305,000 cubic feet. This, shared among a population of 130,000, gives about forty cubic feet for each individual, being nearly the same comparative supply as in the period of Roman splendour. Such profusion of water altogether transcends our conceptions. The supply of London in the year 1790 was only 2,626,560 cubic feet daily; and even now, when the rivalry of the several water companies has almost deluged the streets, it amounts only to 3,888,000 cubic feet. This quantity is abundantly sufficient for all the wants of a luxurious mass of inhabitants, equal certainly to the population of ancient Rome, where the consumption, however, was still fourteen times greater. How paltry then appears the actual supply of Paris, amounting only to 293,600 cubic feet of water in a day. It affords scarcely half a cubic foot, or thirty pounds avoirdupois, to each inhabitant in a population of 600,000. The Greeks of the Lower Empire had simplified the general mode of conducting water. This evidently appears from the practice which now prevails in supplying the city of Constantinople. The ground is levelled by means of the Terazi, a sort of inverted mason's plummet, which hangs from the middle of a cord stretched between two rods divided into inches and parts, set upright, and removed successively from one station to another. But the chief improvement consists in substituting, for the columnaria of the Romans, the Souterazi or water-balance, a sort of hydraulic obelisk or pyramid. By this ingenious contrivance, the expense of aqueducts is reduced to a fifth part. The water runs down with a gentle slope in covered drains, till it reaches an obelisk constructed of masonry; and rising up the one side, by a narrow channel, discharges itself into a basin at the top, from which again, at a level eight inches lower, it descends by a similar channel on the other side. The form of this hydraulic pyramid may be easily represented by the reader, without the aid of any diagram to assist his conception. Such auxiliary machines, which facilitate the escape of the air, and allow the water to settle, are commonly erected at intervals of about two hundred yards. The system is, in fact, only a repetition of conduits. From each separate basin, the water is distributed by orifices of different diameters, but having their centres all in the same horizontal line, three inches beneath the brim. The charge of the waterworks at Constantinople is intrusted to a body of 300 Turks and some Albanese Greeks, who form almost an hereditary profession. According to the interesting work of General Andreossy on the Bosphorus, that for the supply of a population of 600,000 is only two-thirds of a cubic foot, or about forty pounds of water per day. There still remain at Constantinople two ancient cisterns: 1. The Subterranean cistern, built of hard brick, vaulted and resting on marble columns: and 2. The cistern of one hundred and one columns, called anciently Philoxene; it consists of three rows of columns, one above another, and capable of holding five days' supply for the whole inhabitants of this spacious city.—*Leslie's Natural Philosophy.*

**AQUILA**, a constellation in the northern hemisphere, usually joined with Antinöus. According to some ancient poets, this eagle is the same as that whose form Jupiter assumed when he carried to mount Ida the beautiful Gany-mede, son of Tros, king of Phrygia. Antinöus was a youth of Bithynia, (now Anatolia, in Asia Minor,) a great favourite of the emperor Adrian, who erected a temple to his memory, and placed him among the constellations. The asterism Antinöus is generally considered an integral part of the constellation Aquila. Athair, the chief star, and of the first magnitude, is situated in the eagle's neck; its right ascension is  $295^{\circ} 29' 48''$ ; and its declination is  $8^{\circ} 23' 57''$ . It appears on the E.N.E.

three-fourths east point of the horizon, at London, and rises and culminates as in the following Table: Meridian Altitude,  $46^{\circ} 52' 57''$ .

**AQUILEGIA**, columbine, the leaves, flowers, and seeds of which were formerly in great repute among the people for throwing out the small pox and measles.

**ARA**, the Altar, an asterism south of the Scorpion's Tail, contains nine stars, of which three are of the third magnitude, four of the fourth, &c. The chief star culminates nearly at the same time with Ras Algothi in the head of Hercules. See **HERCULES**.

**ARABIS**, bastard tower wall-cress.

**ARABLE LANDS**, those which are fit for tillage, or have been tilld.

**ARACK**, or **INDIAN TODDY**, the juice of the cocoanut tree; or a distillation of rice fermented with toddy. The Tartars have a species of arack distilled from mare's milk.

**ARÆOMETER**, or **WATERPOISE**, fig. 82, an instrument to measure the density or gravity of fluids, is usually made of glass, a round hollow ball terminating in a long slender neck, hermetically sealed at top, there being first as much running mercury put into it as will keep it swimming in an erect position. The stem is divided into degrees, and by the depth of its descent into any liquor, the lightness of that liquor is ascertained, for that fluid in which it sinks least must be heaviest: and that in which it sinks lowest, lightest. See **HYDROMETER**.

**ARBOR**, in Mechanics, a spindle, or axis, whereon a machine turns; as, the arbor of a crane, a mill, &c.

**ARBOR DIANÆ**, or *Tree of Diana*. Half an ounce of fine silver, and two drachms of mercury, dissolved separately in a quantity of aquafortis, are then mixed together, and poured into a pint of common water, and stirred about, that the whole may be well mixed. This preparation is kept in a bottle well corked. In a glass globe, or other vessel, put the amalgam of silver with mercury, the quantity of a small nut; pour three or four ounces of the above liquor over it, and, some hours after, there will arise from the globular amalgam small branches, which, by increasing, will form a beautiful silver shrub.

**ARBOR MARTIS**, or *the Tree of Mars*. Dissolve iron filings in aquafortis moderately concentrated, till the acid is saturated: then add to it gradually a solution of fixed alkali, (oil of tartar per deliquium.) A strong effervescence will ensue, and the iron, instead of falling to the bottom of the vessel, will afterwards rise, and cover the sides, forming a multitude of ramifications heaped one upon the other, which will pass over the edge of the vessel, and extend themselves on the outside with all the appearance of a plant.—*Silver Tree on Glass*. Put a few drops of the solution of silver in aquafortis on a piece of glass, form a bit of copper or brass wire to represent a tree with its branches, but flat, so as to lie upon the glass; lay it in the liquid, and let it remain for an hour or two. A beautiful vegetation will be perceived all round the wire, which will nearly be covered by it. This may be preserved by washing it very carefully with water, and putting another glass over it.—*Lead Tree*. Dissolve an ounce of sugar of lead in a quart of clear water, put it into a glass decanter or globe, then suspend in the solution, near the top, a small piece of zinc of an irregular shape. Let it stand undisturbed for a day, and it will begin to shoot out into leaves, and apparently to vegetate. If left undisturbed for a few days, it becomes extremely beautiful: but it must be moved with great caution. It may appear to those unacquainted with chemistry, that the piece of zinc actually puts out leaves; but this is a mistake; for if the zinc be examined, it will be found nearly unaltered. This pheno-

Fig. 82.

menon is owing to the zinc having a greater attraction for oxygen than the lead has, consequently, it takes it from the oxide of lead, which re-appears in its metallic state.

**ARBUTUS**, or **BEARBERRY**. Its leaves are employed either as a powder or decoction, in gravelly complaints. Boiled in an acid, these leaves will dye brown.

**ARCADE**, an opening in the wall of a building formed by an arch: thus, in London, there is the Burlington arcade; the Royal arcade, a dismal passage behind the Opera House.

**ARCH**, a portion of the circumference of a circle, or curved line; yet arches are sometimes straight lines, as the beautiful arches of the portico of St. Andrew's Church, Glasgow, than which there is not a finer piece of architecture in the kingdom. **Triumphal ARCHES** are magnificent entries into cities; as the arch of Titus (*see the Plate*;) and that of Constantine, at Rome; the gate of St. Dennis, Paris, &c.

In fig. 84, **AS'ESB** is the ponderating arch; **A** or **B** the spring of the arch; **D** its crown; **AB** its span; **CD** its height, or versed sine, or rise; **ADB** the intrados, or the lower surface of the arch, (often called the *arch*); **S'ES** the extrados, being in bridges the superior surface, or the roadway; **F'F** the flanks or lances; the spaces above these are called the spandrells; the portions of stone resembling wedges, which lie in a course contiguous to the intrados, are called voussoirs, or arch stones; at **D** the key-stone: the walls or masses **PQTS**, **P'Q'T'S'**, built to support the arches, and from which they spring as their bases, are either called piers or abutments: piers, when they stand between two neighbouring arches; and abutments, when they support the arches which are contiguous to the shore: the part of the pier from which the arch springs is called the impost; the curve formed by the upper sides of the voussoirs, the archivolt; and the lines **F'F**, **S'S**, about the flanks, in which a break is most likely to take place, the joints of the fracture.

Definition of an Arch.

**ARCHERS**, the royal company of, in Scotland, are his majesty's body guards within seven miles of Edinburgh; and upon the visit of his majesty George IV. to this part of his dominions, the royal company of archers, 1000 strong, dressed in their tartan white and green, with their standards, &c. were acknowledged and received as the body guard of the sovereign, 1822. They claim this privilege by a statute of James I. 1603.

**ARCHES' COURT**, an ecclesiastical court of appeal, belonging to the archbishop of each province.

**ARCHIL**, purple rock lichen, grows upon rocks in England and Wales, and when properly prepared, imparts to woollen cloth a reddish brown; or dull, but durable crimson. It is sometimes used as a styptic.

**ARCHIMEDES**, of Syracuse, one of the greatest and most celebrated of the ancient mathematicians, was born in the above city about 240 years before Christ. The great and comprehensive genius of this author led him to the study of every branch of science; arithmetic, geometry, mechanics, optics, hydrodynamics, were alike the objects of his investigations, and experienced alike the powerful effects of his superior talents. To Archimedes we owe the first idea of the specific gravity of bodies, which arose out of the following circumstance. Hiero, king of Syracuse, having had reason to suspect that a goldsmith, who was employed to make him a crown of gold, had adulterated the metal by mixing with it a quantity of silver, requested Archimedes to endeavour to discover the cheat; which he did, by procuring two masses of gold and silver of equal weight with the crown, which he immersed in a vessel full of water, and carefully noticed the quantity of water which each displaced; after which, he observed how much the

crown caused the same water to flow over; and on comparing this quantity with each of the former, he was able to ascertain the proportions of gold and silver in the crown. He is the reviver at least of the Egyptian mechanics.

**ARCHIMEDES' SCREW**, fig. 85, or the water snail, is a machine for raising water, consisting of a flexible tube rolled

in a spiral form round a cylinder, as in the figure. The water enters at **C**, and descends at first in the spiral canal by its specific gravity, but the cylinder being turned, the water moves to **E**, into the canal, to occupy the lowest place; and thus by the continual rotation, it passes up to **H**, **O**, **G**, **F**, &c. to **D**, where it is to be discharged. The machine is turned by the winch **K**; the prop **IR** supports it, and the extreme axis is fixed in a socket **P**.

**ARCHITECTURE**, the art of Building, has from the earliest periods of society been cultivated by mankind; and the origin of all buildings may be deduced from the construction of the meanest huts. These were, at first, made, as fig. 86, in a conical figure, which is the simplest in structure, but being inconvenient on account of its inclined sides, both the figure and construction of the huts were changed, by giving them the form of a cube. Mankind at length improved in the art of building, and invented methods of rendering their habitations durable and convenient. The trunks of trees, deprived of their bark and other inequalities of surface, were raised above the humid soil by means of stones, and covered each with a flat stone or slate, as

fig. 87, to exclude the rain; and the interstices between the ends of the joints were closed with wax or clay. The roof was altered, and elevated in the centre by rafters, to support the materials of the covering, and to carry off the water. When the rude builder erected more

stately edifices, he imitated those parts which, from necessity, had composed the primitive huts. The upright trees, with stones at each end, became the origin of columns, bases, and capitals; and the beams, joists, and rafters, as fig. 88, which formed the covering, gave rise to architraves, friezes, and cornices. The Greeks, whose genius prompted them to combine elegance and convenience, derived their ideas of building from the Egyptians. But the mind of man is influenced by the government under which he lives; the Greeks, with their independence, lost the ascendancy in works of genius, and

and cornices. The Greeks, whose genius prompted them to combine elegance and convenience, derived their ideas of building from the Egyptians. But the mind of man is influenced by the government under which he lives; the Greeks, with their independence, lost the ascendancy in works of genius, and

## D O R I C.

IONIC ARCHITECTURE, PL. II. MOULDINGS

CORINTHIAN

COMPOSITE

from that period the Romans encouraged this noble art. Vitruvius, the learned Roman architect, had Julius Cæsar and Augustus for his patrons, and though employed in few works of magnificence, his rules for architecture were highly esteemed by the ancients, and are still a standard among the moderns. The Romans carried to the highest perfection the five orders of architecture: the Tuscan, the Doric, the Ionic, the Corinthian, and the Composite; and though the moderns have materially improved the general structure of buildings, nothing has been added to the beauty and symmetry of these columns. To give an idea of the Orders, it must be observed, that the whole of each is divided into two parts at least; the column and entablature: and of four parts at most, when there is a pedestal under the column, and an acroter at, or little pedestal, surrounded by, the entablature: that the column has three parts, the base, the shaft, and the capital; the entablature has three likewise, the architraves, the frieze, and the cornice.

**Orders of Architecture.** (See Plates I. II. III.)—The *Tuscan* Order has its name and origin in Tuscany, first inhabited by a colony from Lydia, whence it is likely the order is but the simplified Doric. On account of its strong and massive proportions, it is called the Rustic order, and is chiefly used in edifices of that character composed of a few parts, devoid of ornament, and capable of supporting the heaviest weights. The Tuscan order will always live where strength and solidity are required. The Etruscan architecture is nearly allied to the Grecian, but possesses an inferior degree of elegance. The Trajan column at Rome, of this order, is less remarkable for the beauty of its proportions, than for the admirable pillar with which it is decorated. Its column is seven diameters high; and its capital, base, and entablature, have but few mouldings or ornaments. All its parts are defined in the Plate, fig. 89; and fig. 90 represents the order complete.—The *Doric* Order, so called from Dorus, who built a magnificent temple in the city of Argos, and dedicated it to Juno, is grave, robust, and of masculine appearance, whence it is figuratively termed the Herculean order. The Doric possesses nearly the same character for strength as the Tuscan, but it is enlivened with ornaments in the frieze and capital. In various ancient remains of this order, the proportions of the columns are different. Ion, who built a temple to Apollo in Asia, taking his idea from the structure of man, gave six times the diameter of the base for the height of the column. Of this order is the temple of Thesus at Athens, built ten years after the battle of Marathon, and at this day almost entire. This order has no ornament on its base, or in its capital; its height is eight diameters; its frieze is divided into triglyphs and metopes. See the Plate, fig. 91, where all the parts of the order are accurately defined; also fig. 92, which gives it complete.—The *Ionic* Order derived its origin from the people of Ionia. The column is more slender than the Doric, but more graceful. Its ornaments are elegant, and in a style between the richness of the Corinthian and the plainness of the Tuscan; simple, graceful, and majestic; whence it has been compared to a female rather decently than richly decorated. When Hermodenes built the temple of Bacchus, at Teos, he rejected the Doric after the marbles had been prepared, and in its stead adopted the Ionic. The temples of Diana at Ephesus, of Apollo at Miletus, and of the Delphic oracle, were of this order. Michael Angelo, contrary to all other authors, gives the Ionic a single row of leaves at the bottom of the capital. See the Plate, fig. 93, for all the parts of the order, and fig. 94, for the finished Ionic.—The *Corinthian*, the finest of all the orders, and as first used at Corinth, is expressive of delicacy, tenderness, and beauty. The capital, so rich and graceful, was suggested to Callimachus by an acanthus entwining its leaves around a votive basket that adorned the grave of an illustrious young lady. This order marks an age of luxury; and the introduction of groups of figures into the frieze of the entablature, shews that pomp and splendour had become predominant passions, but had not yet extinguished a taste for the sublime and beautiful. The double rows of leaves, and eight volutes sustaining the abacus, and modillions in its cornice, are all very fine. The column is 10 diameters high. See Plate, fig. 95, for all the parts; fig. 96, for the entire Corinthian order.—The *Composite* Order, invented, it is said, by the Romans, partakes of the Ionic and Corinthian orders, but principally of the latter. Its

column is 10 diameters high, and its cornice has denticles or simple modillions. The Plate exhibits all the parts in fig. 97; and in fig. 98, the order complete.

Saracenic, or Gothic architecture, had numerous and prominent buttresses, lofty spires and pinnacles, large and ramified windows, ornamental niches and canopies, with sculptured saints and angels, delicate lace-work, fretted roofs, and an indiscriminate profusion of ornaments. The fretwork is so called from the Saxon word *frættan*, signifying fishes' teeth. But its most distinguishing characters are small clustered pillars and pointed arches, formed by the segments of two intersecting circles. This style was of Arabian origin, introduced into Europe by the Crusaders; or those who made pilgrimages into the Holy Land. In the reign of Henry III. many of the old buildings were pulled down to give place to new ones on this model. The cathedral of Salisbury was begun early in this reign, and finished in 1258. It is one of the finest productions of ancient architecture in this island, and is completely and truly Gothic. This term, however, is used by the ignorant, to designate the barbarous compounds we sometimes see set up in imitation of the true Gothic.

The Saxon architecture, of which we have some remains, was the Roman architecture in a decayed state. The style of building practised throughout Europe was of this kind, and so continued to be used by the Normans, with some trifling alterations, till the introduction of the Saracenic architecture about the reign of Henry II. The characteristics are, the semicircular arch, and short, thick, massive columns. It has no pinnacles or pointed ornaments, no delineations of arms, nor statues, except in relief. The best specimen of this style is the north transept of Winchester cathedral. The Norman architecture differs from the Saxon chiefly in its increased proportion, and in the magnitude and massiveness of its buildings, arches highly ornamented with figures of angels, fruit, animals, &c.—subjects serious and ludicrous promiscuously blended together; walls without buttresses, arches supported by solid, clumsy pillars, with a regular base and capital; the capitals adorned with carvings of foliage and animals; the columns with small half columns joined to them, the surfaces ornamented with spirals, squares, network, and figures in relievo. These may be seen in the monastery of Lindisfarne in Holy Island, the

Westminster Hall.

Westminster Abbey. The Norman architecture differs from the Saxon chiefly in its increased proportion, and in the magnitude and massiveness of its buildings, arches highly ornamented with figures of angels, fruit, animals, &c.—subjects serious and ludicrous promiscuously blended together; walls without buttresses, arches supported by solid, clumsy pillars, with a regular base and capital; the capitals adorned with carvings of foliage and animals; the columns with small half columns joined to them, the surfaces ornamented with spirals, squares, network, and figures in relievo. These may be seen in the monastery of Lindisfarne in Holy Island, the

Fig. 100.

Westminster Abbey.

cathedral at Durham, the ruined choir at Orford in Suffolk, and in the crypt or under-croft of Canterbury cathedral.

The Florid Gothic, fig. 101, was admirably adapted for decorative sculptured monuments, screens, altar-pieces, elaborate canopies, ornamental pinnacles, octagonal niches and stalls, with the crocket ornament stealing up the angle, the pyramidal point, crowned with a large flower or a pineapple.

*Common Gothic Arch.*

*Gothic Arch, from Four Centers.*

The arch, as it was described from two points, fig. 102, or from four points, figs. 102 and 103, possessed much grace for pendant decorations of fruits, flowers, and emblazonry. Moreover, sculptures of small imageries in the fretted roofs, characterized this style. The 13th century was the grand era of Gothic luxury, when, and in the succeeding century, were erected the nave and west front of York cathedral, Litchfield cathedral, St. Stephen's chapel, Westminster, (now the House of Commons,) Merton and New College, Oxford. Painted and stained glass now added much to the magnificence of the Gothic windows in those sublime structures. At the western painted window in the church of Batalha, in Portugal, the fathers usually assemble in the choir to chant the evening service, whilst the myriads of variegated rays which emanate from this beautiful window, resemble so many beams of glory playing around them. But the use of glass is of early origin in churches, for the monastery of Wearmouth was glazed in 647; and the windows of York and Canterbury cathedrals, so celebrated for their magnificence, are of early date. During the 13th and 14th centuries, most of the exteriors of our Saxon and Norman churches, as fig. 105, were transformed into the Gothic, which completed the victory of this over

*Saxon Architecture.—Fig. 105.*

every other style in the kingdom. From the end of the 14th century, no remarkable variation can be discovered. Gothic architecture, at this period, had been at its height for nearly two centuries. When Henry VIII. began the Reformation, and the dissolution of monasteries took place, the two universities were at first included in the general ruin; these edifices, however, sacred to science as well as to religion, were saved

from that dilapidation which many of the monasteries and cathedrals experienced. The desolating hands of those reformers who succeeded Henry VIII. destroyed many of the most beautiful specimens of this style of architecture, and despoiled them of their most beautiful ornaments. Castellated Gothic was generally used in that age, when the feudal system rendered it necessary that noblemen should possess fortified castles. This style resembles the original Saxon and Norman architecture.

*Modern Architecture.*—Gothic architecture began to decline from the time of Henry VIII. A style, in which the Grecian and Gothic were mixed together, then prevailed; but in the 16th and 17th centuries the chaste architecture of the Greeks and Romans was revived. The first improvements took place in Italy, whence they passed into other parts of Europe; and though the Italians were long accounted the first architects, England produced Inigo Jones and Sir Christopher Wren, who hold the most exalted station. The banqueting-house at Whitehall, queen Catherine's chapel at St. James'; the piazza of Covent Garden, and many other public buildings, are monuments of the taste and skill of Inigo Jones. The churches, royal courts, stately halls, magazines, palaces, and public structures, designed by Sir Christopher Wren, are proud trophies of British talent. If the whole art of building were lost, it might be again recovered in the cathedral of St. Paul, and in that grand historical pillar, called the Monument. To these, we superadd Greenwich Hospital, Chelsea Hospital, the Theatre at Oxford, Trinity College Library, and Emanuel College, Cambridge; the churches of St. Stephen in Wallbrook, St. Mary-le-bow, and fifty-two others in London, serve to immortalize his memory. While we contemplate these, and many other public edifices erected and repaired under his direction, we are at a loss which most to admire—the fertile ingenuity, or the persevering industry, of the artist. The architectural history of the 18th century differs from that of preceding ages in two essential circumstances. The public buildings erected during this period are, in general, not so grand and massive as those of some former periods. But while they fall short of splendour and magnificence, they are superior to most ancient structures in simplicity, convenience, neatness, and elegance. Private dwellings have been made more spacious, convenient, and agreeable to a correct taste, than in any preceding period. The liberal use of glass, in modern buildings, contributes greatly to their beauty and comfort, and is a point in which the ancients were totally deficient. In descending to the various minute details of human dwellings, especially those which have reference to elegance and enjoyment, it is obvious the artists of the 18th century exceeded all others. During the reign of his present gracious Majesty, the artificer and architect have had the fullest scope for the exercise of their respective talents, whether we consider the vast number of new churches and chapels that have been erected, and that are still building; or

*Stepney New Church.—Fig. 106.*

the extensive improvements which the metropolis has undergone. But all these are outdone by the buildings in the New

Town of Edinburgh, and in Glasgow, where the whole of the very magnificent and classical edifices that have been reared, are constructed of durable free-stone, and decorated in a style that does equal honour to the genius of the people, and the spirit of the age. It would be impossible in this work to enumerate and describe the new churches which have been built since the year 1818. We may, however, give as a specimen *Stepney New Church*, fig. 106, which will hold 1500 persons, two-thirds being in free sittings.

**Architectural Ornaments.**—Balusters are pillars of wood, stone, and used to ornament the tops of buildings, and to support railing; when continued, they form a balustrade: Caryatides, figures of women dressed in long robes after the Asiatic manner, to support entablatures in buildings. Other female figures have been used for a similar purpose, but the original name is still retained. A war had been carried on by the Athenians against the Carians; the latter were totally vanquished, their wives were made captives, and to commemorate this event, trophies were made by the Athenians, in which figures of women, habited in the Caryatic manner, were used for the purpose just explained, and this is in fact the origin of this part of architecture. Persians, so called from a victory gained over the Persians by Pausanias, who having brought home prisoners, spoils, and trophies to the Athenians, they chose Persian male figures to support the entablatures which have been changed in the same manner as the Caryatides. Persians may be of another size; the larger, the greater the effect which they impress on the spectator's mind. In arsenals, galleries of armour, &c. they are advantageously used. Pilasters have their bases, capitals, and entablatures, the same as those of columns but are square, not round as columns are. A Portico is a range of columns covered at the top; that of Palmyra was 4000 feet long. Termini, figures anciently used to mark the limits of possessions, are still used in the human shape as ornaments for temples and garden edifices. There are many other architectural terms, which will be found described under their respective names. See the annexed Plate.

In the *practice of Architecture*, every gentleman is guided by circumstances; but the choice of situation seems to be dictated, in most cases, by the nature of things. A farmer ought to dwell in the centre of his farm; a man of fortune builds for health, neighbourhood, prospect, situation, &c. As regards the construction of edifices, the distribution of apartments, &c. the rules and plans that might be given would fill many volumes; and Aquatic Buildings, Bridges, Harbours, Roofs, Arches, &c. are all described and illustrated under their respective titles, in the work.

**ARCHITRAVE**, that part of a column which lies immediately upon the capital, being the lowest member of the entablature; and the

**ARCHIVAULT**, is the interior contour of an arch or band, adorned with mouldings, running over the faces of the arch stones, and bearing upon the impost.

**ARCHIVE**, a chamber in which records are kept, as the Rolls' Office, in which the archives of the Court of Chancery are kept.

**ARCHYTAS**, a Pythagorean philosopher, and distinguished mathematician, of Tarentum, who flourished about 400 years before Christ, and to whom Aristotle is said to have been indebted for his ethical principles and maxims. To the ingenuity of Archytas, as a mathematician, we owe the method of finding two mean proportionals, mechanically, between two given lines, with a view to the duplication of the cube; and we derive from his skill in mechanics, the invention of the screw, crane, and various hydraulic machines; flying pigeon, or winged automaton. The astronomical and geographical knowledge of Archytas is celebrated by Horace in a beautiful ode, recording also his death, which was occasioned by a shipwreck:—

“ Archytas, what avails thy nice survey  
Of ocean's countless sands, of earth and sea?  
In vain thy mighty spirit once could soar  
To orbs celestial, and their course explore;  
If here, upon the tempest-beaten strand,  
You lie confin'd, till some more lib'ral hand  
Shall strew the pious dust in funeral rite,  
And wing thee to the boundless realms of light.”

**ARCTIC**, the North Pole, because the last star in the tail of the Little Bear is near the pole of the world.

**ARCTIC Circle**, a lesser circle of the sphere  $23\frac{1}{2}^{\circ}$  from the north pole.

**ARCTIUM**, burdock.

**ARCTURUS**, a star of the first magnitude in the constellation Arctophylax, or Boötes; see Job ix. 9. xxxviii. 32. This star is supposed to be nearer our earth than any other in the northern hemisphere.

**AREA**, any plane surface on which we walk, &c. or the site

on which any building stands, or the superficial contents of any figure. Thus, if a field be 40 feet on each side, the contents will be  $40 \times 40 = 1600$ ; or it contains 1600 little squares, each one foot, one inch, &c. every way. In fig. 107, each little  $\square$  contains 10 feet, therefore the 16 squares contain 1600 feet.

**ARECA**, faufel nut.

**AREOLA**, the colour surrounding the nipple of the breast.

**AREOPAGUS**, rock of Mars, a sovereign tribunal at Athens, famous for its justice and impartiality.

**ARETHUSA**, a marsh plant, that requires to be kept moist in two-thirds peat and one-third loam.

**ARGOPHYLLUM**, white leaf.

**ARGO NAVIS**, the ship Argo, a southern constellation, and type of the vessel in which Jason sailed from Thessaly to Colchis, on the east coast of the Black sea, to recover the golden fleece. More properly, this ship is a type of the ark of Noah. The constellation Argo Navis is bounded on the north by Monoceros and Pyxis Nautica, anciently of course by the Water Snake and the Little Dog; east by Robur Caroli, anciently by the Centaur; south by Piscis Volans and Equuleus Pictorius; and west by Canis Major and Columba Noachi. There are sixty-four stars in Argo, reckoning by the Britannic Catalogue, viz. one of the 1st magnitude, six of the second, nine of the 3d, nine of the fourth, &c. The brilliant Canopus, situated near the keel, has  $52^{\circ} 36'$  south declination, and its right ascension in time is 6 ho.  $20' 1''$ , or  $95^{\circ} 15'$ , and though invisible in our northern latitude, it culminates as follows:—

| MONTH. | CULM.<br>ho. mi. | MONTH. | CULM.<br>ho. mi. | MONTH. | CULM.<br>ho. mi. |
|--------|------------------|--------|------------------|--------|------------------|
| Jan.   | 11 31 A.         | May    | 3 47 A.          | Sept.  | 7 36 M.          |
| Feb.   | 9 24 A.          | June   | 1 44 A.          | Oct.   | 5 27 M.          |
| March  | 7 31 A.          | July   | 11 36 M.         | Nov.   | 3 22 M.          |
| April  | 5 37 A.          | Aug.   | 9 32 M.          | Dec.   | 1 49 M.          |

A small part of the Ship's poop only appears above the horizon of Britain, and it is superfluous therefore to trace any combinations among the stars of this constellation.

**ARGUMENT**, in Astronomy, is in general a quantity upon which another quantity or equation depends, or some circumstance relating to the motion of a planet; or it is an arch, whereby we seek another unknown arch, bearing some proportion to the first: hence,

**ARGUMENT of Inclination**, or *Argument of Latitude*, of any planet, is an arch of a planet's orbit, intercepted between the ascending node and the place of the planet from the sun, numbered according to the succession of the signs.

**Annual ARGUMENT of the Moon's Apogee**, or simply *Annual Argument*, is the distance of the sun's place from the place of the moon's apogee; that is, the arc of the ecliptic comprised between those two places.

**ARGUMENT of the Parallax**, denotes the effect it produces on an observation, and which serves for determining the true quantity of the horizontal parallax.

**ARGUMENT of the Equation of the Centre**, is the anomaly, or distance, from the apogee or aphelion; because this equation is calculated in an elliptic orbit for every degree of anomaly, and varies according to the variation of the anomaly.

**ARIES**,  $\gamma$ , the Ram, or Lamb, the first of the zodiacal signs; agreeably to the fixed zodiac of Hipparchus; when the sun enters Aries on the 20th of March, and the vernal equinox begins. From this point we reckon the right ascension of the stars, and the longitudes of the celestial bodies. The fact is

the earth is at this season of the year in Libra, and the sun, as seen from the earth, appears in Aries. The boundaries and contents of this constellation are, north by Triangula and Musca, east by Taurus, south by Cetus, and west by Pisces. This sign contains 66 stars, viz. one of the 2d magnitude, one of the 3d, two of the fourth, &c. The chief star in Aries, called *a Arietis*, is situated in his forehead. Its declination is  $22^{\circ} 36' 30''$ , and its right ascension  $29^{\circ} 15' 30''$ . It rises on the N. E.  $\frac{1}{2}$  E. point of the compass, at London, and culminates on the first day of each month, as in the following Table: Meridian Altitude,  $6^{\circ} 5' 30''$ .

| MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. | MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. |
|--------|-------------------|------------------|--------|-------------------|------------------|
| Jan.   | 11 0 M.           | 7 15 A.          | July   | 10 50 A.          | 7 5 M.           |
| Feb.   | 8 37 M.           | 5 0 A.           | Aug.   | 9 0 A.            | 5 5 M.           |
| Mar.   | 6 45 M.           | 3 15 A.          | Sept.  | 7 0 A.            | 3 8 M.           |
| April  | 4 56 M.           | 1 15 A.          | Oct.   | 5 15 A.           | 1 18 M.          |
| May    | 3 0 M.            | 11 30 M.         | Nov.   | 3 20 A.           | 1 30 A.          |
| June   | 1 0 M.            | 9 30 M.          | Dec.   | 1 15 A.           | 9 30 A.          |

ARISTÆUS, an eminent geometrician of Crotonia, who lived 330 years before Christ; and was author of five books on the Conic Sections, which, however, have never been transmitted down to us, though those of his contemporary Menechmus, have been preserved.

ARISTARCHUS, a celebrated Greek astronomer and philosopher, born at Samos, flourished about the middle of the third century before Christ. Aristarchus is well known to have maintained the modern opinion with regard to the motion of the earth round the sun, and its revolution about its own centre or axis. He also taught, that the annual orbit of the earth is but merely as a point, compared with the distance of the fixed stars. He determined the distance of the sun from the earth, and concluded, that it contained at least 18 or 20 times that of the moon from the earth. Aristarchus likewise found, that the diameter of the moon bears a greater proportion to that of the earth, than that of 43 to 108, but less than that of 19 to 60; so that the diameter of the moon, according to his statement, should be somewhat less than a third part of the earth. He also estimated the apparent diameter of the sun at the 720th part of the zodiac. Besides his astronomical discoveries, Aristarchus invented a peculiar kind of hemispherical sundial. The only work of this ancient astronomer now extant, is a treatise "on the Magnitude and Distances of the Sun and Moon," published by Wallis, with his own notes, and Commandine's version at Oxford, in 1683, 8vo.

ARISTOLOCHIA, birthwort.

ARISTOTELIAN, any thing relating to the doctrines or philosophy of Aristotle.

ARISTOTELIAN *Philosophy*, the philosophy taught by Aristotle, and maintained by his followers. It is otherwise called the Peripatetic Philosophy, from their practice of teaching while they were walking. The principles of Aristotle's philosophy are: Instead of the more ancient systems, he introduced *matter, form, and privation*, as the principles of all things; but it does not appear that he derived much benefit from them in natural philosophy. His doctrines are for the most part so obscurely expressed, that it has not been yet satisfactorily ascertained what his sentiments were on some of the most important subjects. He attempted to confute the Pythagorean doctrine, concerning the two-fold motion of the earth; and pretended to demonstrate, that the matter of the heavens is ungenerated, incorruptible, and not subject to any alteration; and he supposed that the stars were carried round the earth in solid orbs.

ARITHMETIC, the science of numbers, whose several rules of Addition, Subtraction, &c. will be found under their respective heads. The marked superiority, indeed, of our present numeral system over that of the ancients, is so conspicuous, that since the time of its first introduction into Europe, nearly all knowledge of the more imperfect and obscure methods before used is obliterated and forgotten; and even the slight vestiges of these abandoned monuments, which now remain, have become so rare and difficult to be traced, either in the original works, in which they might be expected to be found, or in the commentaries and translations of later writers, that except from the scanty relation that has been given of them by

Wallis, and the more recent and ample detail of Delambre, but little further information can be expected on the subject; particularly as it is now well known, that the authors of most of the early performances in which these methods were employed, have contented themselves with barely giving the results of calculations, without shewing the nature of the process, or the different steps of the operation.

ARK, a floating vessel built by Noah, about which, all beyond the account of scripture, is mere conjecture, and had much better be omitted in this work. The truth, as related under the unerring direction of the divine Spirit, is found in Genesis.

ARK of the *Covenant*, a chest in which the Israelites kept the golden pot that contained the manna, Aaron's rod, and the tables of the covenant.

ARMED, a cross-bar is said, by sailors, to be armed, when some rope yarn, or the like, is rolled about the end of the iron bar, which runs through the shot. In Heraldry, the horns, feet, beak, and talons of birds of prey, are *armed*, when of a different colour from the body. An *armed ship* is, properly, one of the government vessels. See SHIP OF WAR.

ARMIGER, a title of dignity to such gentlemen as are entitled to bear arms by courtesy or creation.

ARMILLARY SPHERE, an artificial sphere composed of various brass circles, to illustrate the imaginary lines with which the earth is supposed to be surrounded. See *Sphere*.

ARMOUR, a defensive dress, worn to secure the body in battle, &c.; *armour cap-a-pée* consisted of a casque or helm, gorget, cuirass, gauntlets, tasses, brassets, and covers for the legs, to which the spurs were fastened. Lastly, the horses even had their armour to cover the head and neck.

ARMOURY, a storehouse for arms; as the Tower, the arsenal of Woolwich, &c. In Heraldry, arms are marks of dignity and honour, and are, like titles, hereditary; expressing, on the field of the escutcheon, the degree, merit, and quality of the original bearers. The ancient armour was tried and proved by raising it to a sufficient height, and then letting it fall on a large stone or pavement: if it was not injured by fracture, it was good.

ARMY, a large number of soldiers, consisting of horse and foot completely armed, and provided with artillery, ammunition, provisions, &c. under the command of one general-officer, having under him a general of horse and one of foot, a major-general for every two brigades, and nearly half as many lieutenants-general.

ARNICA, leopard's bane.

AROMATIC VINEGAR, an acetic solution of camphor, oil of cloves, oil of lavender, and oil of rosemary; take a sufficient quantity of each to make it pleasant, and mix them together.

ARPENT, a measure of an 100 perches square.

ARRAIGNMENT, in Law, to call a person to answer in form of law upon an indictment; and the ARRAY is the ranking or setting forth of a jury, or inquest of men impannelled on a cause. An ARREST, is the restraint or beginning of imprisonment of one's person, by a lawful warrant, and is either *civil* or *criminal*. When any one is arrested for a criminal offence, the officer who arrests him is bound, (by the habeas corpus act,) under heavy penalties, to deliver to the prisoner, or his agent, within six hours after demand, a copy of the warrant of commitment, in order that no one may be imprisoned from malice or revenge, or without knowledge of the charge against him. In case such copy is denied, on complaint in writing on oath, the lord-chancellor, or any of the twelve judges, provided it is a bailable offence,—or on affidavit, that a copy is denied,—can award a writ of *habeas corpus* for such prisoner to be brought immediately before him; and he is obliged to discharge the party, on receiving bail. See ASSIZE.

ARRESTS, in Farriery, mangy tumors upon a horse's hinder legs, between the ham and the pastern.

ARRONDEE, in Heraldry, the curved cross, whose arms terminate in the edge of the escutcheon.

ARSENAL, a royal or public magazine, for the making or keeping of arms, naval or military furniture and equipments, &c., as the arsenal of Woolwich, of Toulon, &c.

ARSON, the malicious burning of a house, &c. of another man, which is felony at common law.

ART, the application of knowledge to practice; hence we have the terms *useful* or *mechanic*, *liberal* or *polite arts*; the

former requiring manual labour principally, the latter requiring the exercise of mind more than of the hand and body.

**ARTEMISIA**, mugwort.

**ARTERY**, a conical tube, or canal, which conveys the blood from the heart to all parts of the body. See **ANATOMY**.

**ARTICHOKE**, a well-known plant, grown chiefly for culinary uses, and eaten with melted butter and pepper, either plain, boiled, or stewed, and added to ragouts, and highly seasoned dishes. The leaves and stalks contain a bitter juice, which, melted with an equal portion of white wine, has been successfully employed in the cure of dropsy, when other remedies have failed.

**ARTICLES OF FAITH**, doctrines of Christianity, allowed and established by the church for our belief. The thirty-nine articles were confirmed by royal authority in 1652. The law requires a subscription to these articles, of all persons ordained to be deacons or priests; of all clergymen inducted to any ecclesiastical living; of licensed lecturers and curates; of the heads of colleges, chancellors, officials, commissaries, and schoolmasters. Dissenting teachers are to subscribe all, except the 34th, 35th, and 36th, and part of the 20th, (and in the case of Anabaptists, except also part of the 27th,) otherwise they are exempted from the benefits of the Act of Toleration, 13 Eliz. cap. 12, 13, 14. Chas. II. cap. 4. 1 Will. III. cap. 12.

**ARTIFICER**, a manufacturer of any commodity, as a smith, carpenter, &c. The artificers of Rome were exempt from all personal services, and incorporated into companies, enjoying their peculiar temples and tutelary gods; but still they were treated with contempt, most of them being slaves and foreigners, whose poverty exempted them from taxes, and whose equivocal character rendered their names unfit for the censors' books, and their persons for war. How much the state of the artificer is bettered since Rome gave law to the world, the prosperity, liberty, and opulence of Great Britain sufficiently prove. Still by the English laws, artificers in wood, iron, steel, brass, or other metal, are prevented, by statute, from quitting the kingdom. And such as go abroad, and do not return on warning given by our ambassadors, shall be disabled from holding lands by descent and demise, and from receiving any legacy, &c. and be deemed aliens. A heavy penalty is also inflicted on persons seducing artificers to go abroad. Statutes, 5 Geo. I. cap. 27; 23 Geo. II. cap. 13. § 1.

**ARTILLERY**, the science which the officers of artillery ought to possess; or the soldiers destined for the service of guns, cannon, mortars, &c. The artillery of Britain consists of both horse and foot soldiers, whose chief rendezvous is at Woolwich.

**ARTILLERY Park**, the place in the rear of both lines of an army for encamping the artillery, which is drawn up in lines, of which one is formed by the guns; the ammunition waggons make two or three lines sixty paces behind the guns, and thirty distant from one another: the pontoons and tumbrils make the last line. The whole is surrounded by a rope fastened to stakes, defining the camp ground; and the gunners and matrosses encamp on the flanks; and the bombardiers, pontoon men, and artificers, in the rear.

**ARTOCARPUS**, the bread-fruit tree, grows wild in Otaheite, and other islands of the South Seas. It is about 40 feet in height, with large spreading branches, and bright green leaves, divided into seven or nine pea-shaped lobes, and loaded with large globular berries about the size of a child's head; it affords a good nourishment, and from its inner bark there are separated fine white fibres, which are woven into cloth.

**ARUM**, wake-robin, or cuckow pint.

**ARUNDELIAN MARBLES**, are ancient stones, on which is inscribed a chronicle of Athens, engraved in Paros 264 years before Christ; and they take their present name from Thomas earl of Arundel, who procured them from the East, and made a present of them to the University of Oxford. This chronicle begins 1582 years before Christ; but it is so defaced, that the sense is discovered chiefly by conjectures. But in a dissertation, entitled, "The Parian Chronicle," the authenticity of these marbles has been questioned: 1st. Their characters have no certain or unequivocal marks of antiquity; 2d. it is not probable, that the chronicle was graven for private use; 3d. nor by public authority; 4th. it is not once mentioned by any

writers of antiquity; 5th. some of the facts in the chronicle seem to have been taken from the writers of a later date; 6th. Parachronisms appear in some of the epochas; 7th. the history of their discovery is obscure and unsatisfactory. These marbles had been totally unknown or unnoticed for almost 1200 years, and at last are dug out of the ground—nobody can tell us when, or where!

**ASBESTOS**, a native fossil stone, which may be split into threads and filaments from one to ten inches in length, very fine, brittle, yet somewhat flexible, silky, and of a grayish colour. Asbestos is insoluble in water, and possesses the wonderful property of being incombustible.

**ASCENDING STARS**, are such as are rising above the horizon of any given parallel of the equator.

**ASCENDING Node**,  $\Omega$ , that point of a planet's orbit where it passes the ecliptic, to proceed northward.

**ASCENSION**, *Right*, of any of the heavenly bodies, is that degree of the equinoctial counted from the beginning of Aries, which rises with the sun or star in a right sphere. *Oblique Ascension*, an arc of the equator, intercepted between the first point of Aries and that point of the equator which rises together with a star in an oblique sphere; and the ascensional difference is the difference between the right and oblique ascension.

**ASCITES**, dropsy of the abdomen.

**ASCLEPIAS**, swallow-wort.

**ASCYRUM**, Peter's wort.

**ASHES**, the earthy particles of combustible substances after they have been burned; those of vegetable bodies possessing a fixed salt, as potash, pearlash. Ashes are an excellent manure for cold and wet grounds. In their religious ceremonies, the Jews sat on ashes, threw ashes on their heads, and fed on ashes, which, however, is a poetical allusion. There was, nevertheless, a lustral water made with the ashes of a sacrificed heifer, which was distributed to the people, and used in purifications as often as they touched a dead body, or were present at funerals. Numb. xix. 17. 2 Sam. xiii. 9. and Ps. cii. 9.

**ASIA**, extends about 6500 geographical miles east and west, reckoning from the Hellespont to what is called East Cape; and about 4500 geographical miles, north and south, from Cape Ceyro Vostochnoi, on the Arctic ocean, to the southern cape of Malacca. And it contains the following states:—*In the North*. The countries of Siberia, or Russian Tartary; whose chief towns are, Astracan, on the Wolga, Tobolsk, on the Irtysh. *In the Middle*. Countries: the Chinese empire, Chinese Tartary, Tibet, Independent Tartary, Turkey in Asia. Chief towns: Peking, Cashgar, Lassa, Samarcand, on the Sogda, Aleppo, and Jerusalem. *In the South*. Countries: Arabia, Persia, Hindostan, the Birman empire, Malaya, or Malacca. Chief towns: Mecca and Medina, Ispahan and Shiraz, Delhi and Calcutta, Ummerapoora and Ava, Malacca. The religions of Asia are very various: in Turkey the Mahomedan and Christian both prevail; in Asiatic Russia are found the two former, and also a species of Hindooism; the Chinese believe in polytheism; in Tibet, the religion bears a close affinity to that of the Hindoos: in Japan, polytheism obtains; the Birmans are worshippers of Brahma, as are also the Siamese, and the Hindostanese; the religion of Persia is the Mahomedan, as is also that of Arabia, while in the Asiatic islands several of the foregoing faiths have their respective devotees; and there are some insulated savages without any vestige of religious rites. The oceans, seas, bays, and gulfs, belonging to Asia, are: the Arctic, Pacific, and the Indian oceans; the Arabian Gulf, or Red Sea, between Africa and Arabia; the Persian Gulf, between Arabia and Persia, receiving the Euphrates and the Tigris; the Bay of Bengal, separating the peninsulas of India; the Gulfs of Siam and Tonquin; the Yellow Sea, the sea of Japan, and that of Okhotsk. Adjacent to Europe, Asia claims a share in the Levant, the Archipelago, the sea of Marmora, the Black Sea, and the sea of Azof. The Caspian Sea is an inland lake, 700 miles long, and from 200 to 700 broad. The sea of Aral is 200 miles long, and 70 broad; and that of Baikal is 850 miles in length, but only 35 in breadth. The chief Asiatic straits are those of Babel-mandel, Malacca, Sunda, Corea, and Bherings, between Asia and America. The mountains are, the Ouralian chain, forming

the boundary between Europe and Asia; the Altaian chain, extending 6000 miles across the centre of Asia; the mountains of Tibet, the highest on the globe, being in one place above 26,000 feet above the level of the sea; Mount Taurus; the Caucasian chain, Mount-Ararat, Lebanon, and the Gaults of Hindostan. The chief rivers are the Obe, the Enissei, the Lena, the Amour, the Hoan-ho, the Kian-ku, the Maykaung, the Maygne, the Trawadely, the Burrampoot, the Ganges, the Indus, the Godavery, the Kistna, the Euphrates, the Tigris, and the Wolga. The canals of China are very numerous, and facilitate commerce in all directions; while the magnitude of the Ganges, the Indus, and many other rivers, admits of an uninterrupted navigation for nearly 1000 miles, for vessels of 200 tons burden. The Asiatic islands are the Laccadive and Maldive islands, Ceylon, the Nicobar and Andaman isles; the Japanese islands, the Eastern Archipelago, Austral-Asia, and Polynesia.

Turkey in Asia.—This region is divided into nine provinces, extending from the shores of the Archipelago, in Europe, to Persia; and these provinces are subdivided into governments arbitrarily ruled by pashas, or military commanders. The provinces are, Natolia, in the west; Karoman, in the south; and Roum, in the north-east; Guria, Mingrelia, Circassia, north of Armenia, or Turcomania, and south of it are Kurdistan and Irak-Arabi; Mesopotamia, and Syria. The population is estimated at ten millions, and of this mass of human beings, one half are pastoral wanderers, without industry, arts, or civilization. The chief cities are, Aleppo, with a population of 250,000 inhabitants; Damascus, containing 100,000 souls; Smyrna, 120,000; Prusa, 60,000; Angora, 80,000; Tokat, 60,000; Bassora 50,000; and Bagdat, 40,000. Aleppo is famous for its manufactures of silk and cotton; and its numerous mosques, surmounted with white minarets, and relieved in the distant landscape by the tall cypresses, give this elegant city a most picturesque appearance. Damascus for its swordblades is unrivalled; and its manufactures of silk, cotton, and soap, are very considerable. Smyrna is the chief mart of European trade on the shores of the Levant; but the pestilence retards its prosperity. The climate is most excellent; and though the soil be in general good, agriculture in Syria is in a most wretched condition. The chief rivers are the Euphrates, the Tigris, the Kizil-Irmak, or Halys of antiquity; the Meander; the Sarabat, or ancient Hermus; and the Orontes in Syria. The lakes are, Van, in Kurdistan; the Dead Sea, in Syria; the Tata, or Palus Salsa, of Asia-Minor; Ulbad, in Natolia, and the Isnick. The mountains are, the Taurian Chain; the Caucasian mountains; Ararat, in the east of Armenia; Lebanon, in Syria; Olympus and Ida, on the east of the Archipelago. These mountains are clothed with immense forests of pine-trees, oaks, beeches, elms, and other alpine trees, which furnish safe retreats to tigers of the smaller breed, hyenas, wild boars, troops of jackals; and the ibex roves on the summit of the Caucasus; while Angora is celebrated for its singular goats and cats, from whose wool are manufactured Angora shawls, &c. The islands belonging to Asiatic Turkey are, Mytilene, Scio, Samos, Cos, and Rhodes. Mytilene is mountainous, but agreeably diversified with olive gardens, vineyards, and plantations of myrtle. The climate is exquisite, and the coast is finely indented with numerous creeks and havens. Scio, or Chios, contains about 60,000 inhabitants; and the Greeks make a decent livelihood in the cultivation of mastic gum, for the ladies of the sultan's harem. Samos, with a population of 12,000 Greeks, is famous for its pottery, its honey, and wax. Cos is covered with groves of lemon-trees. Rhodes, whose population is 30,000, was once celebrated for its colossal statue in bronze, and its having been possessed by the knights of St. John of Jerusalem. Cyprus is fertile, but agriculture is neglected. Its wines and oranges are excellent, and its hills are bedecked with the most beautiful flowers.

Russia in Asia.—The Russian empire extends along the whole of Asia. If we compute the degree of longitude in that high latitude at 30 miles, the length (reckoning from 37° east longitude, to 170° west longitude) will be about 4590 geographical miles; and its mean breadth cannot be less than 1960 miles, estimating from Cape Vostochnoi to the sea of Baikal. The ancient name of this vast empire was Siberia. The popu-

lation of this extensive empire is almost all of primitive origin, consisting of Samoides, Monguls, Kalmucks, Tartars, &c. And they profess, according to their tribes, the Mahommedan religion, that of the Greek church, or the superstition of Dalai-Lama, &c. The government of Siberia is divided into two branches, that of Tobolsk in the west, and Irkutsk in the east; and the population does not exceed three millions and a half. The Tartars are generally hunters, or herdsmen, feeding horses, camels, oxen, sheep, and goats; and their women busy themselves in tanning leather, gardening, and providing winter provisions. The Kalmucks are divided into three classes, nobles, clergy, and people, and the power of their chief consists in the number and opulence of his subjects. The Monguls are of short stature, with a flat visage, small oblique eyes, thick lips, and short chin, from which depends a scanty beard. Their hair is black, and their complexion a yellowish brown. Like all pastoral tribes, they are docile, hospitable, and active, but voluptuous; and hence industry is a virtue entirely confined to the females. Wandering in herds in quest of sustenance for their flocks, with much mirth they amuse themselves in horse-racing, archery, wrestling, pantomime, dancing, cards, and chess. The chief cities are, Astracan, at the mouth of the Wolga; Azof, Tobolsk, Kolyvan, on the Ob; Irkutsk, the chief mart of commerce between China and Russia. The chief manufactures are, leather, salt, isinglass, kaviar, (the salted roe of a large fish,) and pitch; and the chief articles of commerce are, sables, furs, hides, rhubarb, and raw silks, which are exported, or exchanged, for tea, silk, porcelain, wine, fruit, coffee, rice, woollen cloths, iron, and household goods. In so extensive a country the climate and soil are very various; though in general the former be frigid rather than temperate, the latter might be cultivated to great advantage in the southern and western districts, were the peasantry not sold as slaves with the ground they tread on. The chief rivers are, the Ob, navigable almost to its source, and abounding in fish; the Yenidei, issuing from the Baikal, or Holy Sea; the Selenga, flowing into the Baikal; the Lena, of great breadth, and full of islands; the Wolga, the Amur, and the Onon. The chief lakes are, those of Piazinsko, in the north; the Baikal, in the south; the lakes of Tchany and Soumi, between the Ob and Irtysh; the Bagdo, to the north of the Caspian, is salt water, as is also the Atlan-Nor, or Gold Lake. The mountains are, the Uralian chain; Bogdo-Alim, adjoining the Mongolian desert; the Altaian chain; the Schlangenberg, rich in minerals, as are also the mountains of Nenshinsk; the mountains of Ochotsk, many branches of which consist of red and green jasper; and the classical Caucasus, whose summits are crowned with everlasting ice and snow. Asiatic Russia abounds in forests and *stepps*, or extensive level plains, which resemble the sandy bed of a sea, with scattered patches of thin grass, stunted thickets, spots of salt, and saline lakes. In the forests, the terrible urus and the bear range; the argali, or wild sheep, and the ibex, or rock goat, inhabit the Caucasus; the rein deer performs the office of the horse; the mountains of Baikal abound in large stags; and the white foxes of the Eastern Archipelago rival the monkey in mischievous tricks. The isles belonging to Asiatic Russia are, the Aleutian isles on the east of Kamschatka, the Andrenovian or Fox islands on the west of the former; and the Kurilian isles, extending from the south of Kamschatka to Japan. Several of these isles are volcanic; and they all swarm with foxes.

The Chinese Empire.—This vast empire extends in an easterly direction 4200 geographical miles, and southerly 1740 miles. By glancing at the map of Asia, we perceive it stretching from the Pacific Ocean to the river Sihon, and from the Uralian mountains to the tropic of Cancer. It is divided into three parts, China Proper, the kingdom of the Mandshurs and Monguls, on the north and west, and the territory of Tibet.

I. China Proper.—China Proper (extending from the great wall in the north to the Chinese sea in the south) is 1140 geographical miles long; and in breadth (from the shores of the Pacific to the frontiers of Tibet) it is computed at 880 geographical miles. The religion is polytheism. The government patriarchal: hence the amazing population and general ease and happiness of the people. The population amounts to three hundred and thirty-three millions of souls, the army is one million, and the revenue amounts to nine millions sterling.

The features of the Chinese proclaim their affinity with the Tartars, Monguls, and Mandshurs; and though they appear highly civilized, science is still in its infancy among them, and must ever be so, where, from age to age, genius is cramped by the children following the business of their fathers. The chief cities are Peking and Nankin; the former possessing a population of three millions of souls, and the latter is yet more extensive. In Canton there are a million and a half of inhabitants. The characters of the Chinese people in the different provinces are thus portrayed in the last court calendar of the celestial empire.—1. Peking, or Shun-teen-foo. The people are strong and brave; silent, famous for politeness and justice; plain, unceremonious, and moral, regenerated by their vicinity to the emperor.—Paou-ting-foo. Literati not endowed with remarkable talents, and agricultural people.—Yung-ping-foo. The literati value their reputation; a frugal people, attentive to agriculture.—Tee-tsin-foo. A mixed people from every part of the country; gay and extravagant, some frugal.—2. Keang-see—Keang-nin-foo. An extravagant people, a great number of literati.—Soo-chow. The scholars are very polite, and the people taught to love each other. Their manners are pure, and instruction has a powerful effect.—Sung-keang-foo. The literati are studious, the people eminent for benevolence.—3. Gan-hwuy. A light unsteady people; economical, and of good appearance.—4. Keang-se. The literati are partial to classical learning, the people attentive to husbandry.—5. Che-keang.—Hang-chow-foo. Gems and rarities are here collected. Foreign and home trade are united. The people are genteel and elegant. The literati are very methodical.—6. Fo-keen, Fo-chow-foo. Inwardly sincere, and of a gay exterior; very attentive to business, and value economy.—7. Hoo-pee, Woo-chang-foo. A mixture from every part of the empire. Every family observes its own customs. The Chinese roads are excellent, and no country excels this in inland navigation. Irrigation is very well practised, husbandry is neat and clean, and the emperor himself is not ashamed to hold the plough in its season, and sets an annual example of the veneration due to the chief branch of human industry. The lakes are noble and extensive, and afford vast quantities of fish, which are taken by trained birds. The rivers are the Kian-ku and the Hoan-ho. The mountains, though numerous, have not yet been accurately described; and except in the loftiest districts, cultivation has annihilated all the great forests. Yet tigers, buffaloes, wild boars, bears, rhinoceroses, camels, and deer, find ample shelter. The common people pound their coal with water, and bake it in cakes for use. The Chinese islands are Formosa, Hainan, and the isles of Leoo-keoo, between Formosa and Japan. Their inhabitants form a civilized kingdom, subject to China, and their manners appear mild, affable, gay, and temperate.

II. Chinese Tartary.—Chinese Tartary, or Mongolia, extends over the vast regions between Tibet, China, and the Arctic Ocean; and from the Black Sea to the north-eastern boundaries of Asia. That is to say, from  $72^{\circ}$  to  $145^{\circ}$  east longitude, or seventy-three degrees, equal to 3100 geographical miles, taking the medial latitude at  $45^{\circ}$ ; and from the Russian confines to Tibet, its breadth of  $18^{\circ}$  will give 1,080 geographical miles. The religion is called Shumanism, or the belief in a Supreme Author of nature, who governs the universe by the agency of numerous inferior spirits; but a living Lama, or embodied spirit, is acknowledged and worshipped; and this Lama is a human being like ourselves! The princes pay homage to the Chinese empire; the population amounts to about six millions of souls; and the whole country is divided by the Chinese into the three great governments of Chinyang, Kiren-oula, and Tsitchicar; while the territory of the Oelets or Kalmucks comprises Gete, Little Bucharja, and the countries of Turfan. The chief towns are, Cashgar, Yarkand, and Kotan, in Little Bucharja; Turfan, Hami, Chami; Coucou, Hotun, Tsitchikar, Merguen, Petouna, Kirin, and Nigouta. The chief city of Corea is Kinkatao. The chief trade of these places lies in pearls, horses, musk, and furs. Corea is celebrated for the most exquisite horses, only three feet high. A mare of this breed was exhibited in London, in 1820. The climate, in general, is as mild as that of France and Spain, and the great Table Plain, extending from  $80^{\circ}$  to  $110^{\circ}$  east longitude, or 1380 geographical miles, is the most singular feature

in the face of the country. In all Chinese Tartary the predominating substance of soil is black sand, and agriculture is wholly neglected. The chief rivers are, the Amur or Sagalian-Oula; the Yarkand, and the Ili; the former falling into the lake of Lop, the latter into that of Balkash or Tengis. The mountains are, the Imauan chain, or the Dark Mountains of Belur Tag; those of the Russian frontier, and the mountains of Tibet. The island of Sagalian, or Tchoka, 240 miles north of Jesso, is mountainous towards the centre, but the shores are adapted to agriculture; and the natives dress in loose robes of skin, and live in huts, a mild and intelligent race, unlike the Manshurs.

III. Tibet.—Tibet is about 1350 geographical miles long, and 480 broad, extending from the 75th to the 101st degree of east longitude; and from the 27th to the 35th degree of north latitude. It is divided into Upper, Middle, and Lower Tibet; the first comprising the province of Nagair, full of stupendous rocks, covered with eternal snow; the central region, embracing the provinces of Shang, Ou, and Kiang; while Lower Tibet includes the provinces of Takbo, Congbo, and Kahang. The religion of the Tibetians is closely allied with the Hindoo faith; but differs essentially in its ceremonies. For instance, the Tibetians assemble in temples, chant in alternate recitative and chorus, accompanied by instruments of music; and they have numerous monasteries, inhabited by hosts of *gglongs* or monks, and *annees* or nuns. In a word, they resemble the Catholics. The ruling government is spiritual, but a secular regent manages the affairs of the half million of people who inhabit Tibet. The revenue of the Lama, or pope, and of the secular princes, is trifling. And it is a remarkable fact, that, in regard to polygamy here, the women indulge themselves with pluralities of husbands. The chief city is Lassa, seven miles east of which is the palace of the Lama, or pope. Bridges of chain are common, passing from precipice to precipice. And though there is a great want of industry, the shawls of Cashmir are manufactured from the goats' hair of Tibet. The climate of Bootan is temperate, compared with that of Tibet Proper, whose distinguishing characteristics are extreme aridity and parching cold. And though Bootan be covered with eternal verdure, Tibet Proper presents a peculiarly naked aspect, indicative of rich ores. Its abundance and variety of wild fowl and game, its flocks of sheep and goats, and herds of cattle, have been noticed by all travellers, in all times. The chief river is the Sampoo or Burrampooter, but many of the Asiatic rivers have their sources in Tibet, whose mountains are the Alps of Asia.

Japan.—Japan consists of several islands, extending from the 30th to the 41st degree of north latitude, and from the 131st to the 142d degree of east longitude. The chief of these islands are Nipon and Jesso; but the whole are divided into provinces and districts, with as much method as the most civilized countries of Europe. The established religion is polytheism; the people abstain from animal food, and detest bloodshed; and viewing the gods as beings dispensing happiness, they solemnize their festivals and modes of worship with cheerfulness and even gaiety; nor are they without monks and nuns of different orders, as in Tibet. The government is monarchical, and each province is ruled by a resident prince, who, in pledge of his good administration, is obliged to leave his family as hostages at the emperor's court. And the laws being few, but rigidly enforced, without regard to persons, partiality, or violence, are posted up in every town and village. The population amounts to thirty millions of souls, and the army to 500,000 horse and foot. The revenue has been reckoned thirty millions. This highly civilized people use no wine or spirituous liquors, though their food be various and their sauces numerous. Their dress consists of trowsers and loose gowns or robes of silk, worn alike by both sexes; and in their games and theatrical amusements the Japanese rival the Europeans. In varnishing they have no equals, and in some of their arts and manufactures they excel even the British, the Germans, and the Chinese. The chief town, Jedo, is on the south-east side of Nipon, and Miaco, the spiritual capital, is the second city in the empire. The Dairi, or pope, resides here, and here also all books are printed from stereotype blocks. Japan is exposed to a copious moisture, from the

rains which fall from midsummer to autumn, and the fertility of the country may be attributed to this cause; tempests, hurricanes, and earthquakes, are common. Agriculture is highly esteemed and sedulously cultivated, even on the mountains and hills; and the farmer labours under no restraint from taxes and tithes. Rice is the chief grain; but potatoes, beans, pease, turnips, and cabbages, abound. And the varnish and camphor trees, the vine and the cedar, and the tea-tree, are cultivated. Among the rivers and lakes described by geographers and travellers, we may enumerate the Nogafa, the Jedogawa, the Ojingawa, and the Jodo, as celebrated rivers; and one of the chief lakes seems to be that of Oitz. The mountains are numerous, and intermixed with many sublime volcanoes, and the delightful sacred mountain of Jesan is decorated with no fewer than 3000 temples. Among the islands dependent on Japan, is Fatifo, the place of exile for disgraced grandees, and political offenders, who are spared capital punishment, to endure the more severe chastisement of perpetual banishment.

The Birman Empire.—The Birman Empire includes the space between the 9th and 26th degrees of north latitude, and between the 92d and 107th degrees of longitude east of Greenwich; about 1020 geographical miles in length, and 900 in breadth. The population amounts to seventeen millions; the government is despotic; and a nobleman is distinguished by the number of chains, three, six, nine, or twelve, around his neck. The religion is that of Brahma, belief in the transmigration of souls, and eternal happiness in Mount-Meru. Their navy resembles the Roman galleys; and their army is inconsiderable, though every male is liable to military service. The Birmans are lively, irascible, and impatient; their women are laborious; hence infidelity, the offspring of idleness, is rarely known among them. The great alone are educated, the poor are totally neglected. The chief cities are, Ava, the ancient capital; Ummerapoora, the new capital, resembles Venice in its spires, turrets, and obelisks. It is built on the eastern side of a great river that flows into the Irrawady, amidst numerous islets. Pegu is known chiefly by the temples which Alompra spared when he razed the city in 1757. The Shomadoo, an extraordinary building of Pegu, is 361 feet high, surmounted by the sacred umbrella, fifty-six feet in circumference, and said to have been erected 500 years before Christ. Rangoon, the chief sea-port, contains 30,000 souls; Prome is celebrated as the scene of many sieges; and Aracan, Quantong, Bamoo, Munnipora, and Monchaboo, are considerable places. The inland navigation is most ample, from the numerous rivers and streams. The Birmans excel in gilding, and in carving marble divinities. The seasons are regular, the climate salubrious, and the people vigorous and healthful. The chief rivers are, the Irrawady, which joins the sea by many mouths; the Keen-Duem, the Sitang, and the Thalan. And the mountains are those on the frontiers of Tibet, the range of Anoupee, between Ava and Aracan. The forests are large and numerous, and covered with everlasting verdure. The teak-tree flourishes as lord of the wood, in majesty of form and amplitude of growth. While in comparison of the Birman, our forests sink into vegetables of an inferior order, their shrubs and plants in their blossoms and fruits, by their brilliant colours and aromatic fragrance, reduce to relative insignificance the boasted produce of Italian summers.

Aracan.—In Aracan, the climate is pure, the plains fertile, and the valleys present numerous flocks of cattle; but the natives are averse to commerce and a maritime life. The Aracans will eat rats, mice, and serpents; and fish, to provoke the palate, must be out of season. The monarch lives in solitude and luxury with his queen and harem, which he thinks enriched by a concubine from Jangoma, a small kingdom in the vicinity of the Birman empire, and on the north of Siam. But the women of Jangoma are famed in all the east for their gallantry and beauty. The temples resemble pyramids, and there are three orders of priests, living in perpetual celibacy.

Malaya, or Malacca.—Malaya is an extensive peninsula appended to the Birman territories, and divided into the kingdom of Patani in the north, and that of Johor in the south; the chief towns being Batusabar, the capital, Linga, Bintam, and Carimon. Malacca is 560 miles long and 150 broad; the inhabitants are indolent to agricultural pursuits, but restless

for war, plunder, emigrations, and affairs of gallantry; and the Malayan history is full of desperate enterprises, that sufficiently characterize the ferocity of these Mahomedan barbarians. The peninsula of Malaya abounds in forests, stocked with abundance of wild elephants, whose teeth become a considerable article in the commerce of the natives with the Dutch and Portuguese. Opposite Malacca are the islands of Andaman and Nicobar, whose inhabitants are the most savage in the world; but they may profit by the example of British industry, as a colony has been formed on the greater Andaman for convicts from Bengal.

Siam.—Siam, 700 miles long, and 70 miles in medial breadth, is a rich and flourishing kingdom. The religion resembles that of the Hindoos; the government is despotic; the laws severe; the people amount to eight millions; the army 60,000, with 4000 elephants; the navy is numerous, though the vessels are mere galleys; and there is a royal treasury, but its revenue is unknown to Europeans. The whole country is a wide vale between two ridges of hills, and would be a terrestrial paradise, were it not subject to an absurd despotism, that cramps industry, and would annihilate agriculture, did not vegetation thrive in spite of the worst of governments. The Siamese are small of stature, but well made; and their feeding on rats, mice, lizards, and several kinds of insects which we loathe, but ill accords with their religion, and the products of a country which exports prodigious quantities of grain. In all works of industry the women are employed, while the men pass away their time at theatrical amusements, races of oxen, combats of elephants, cock-fighting, tumbling, wrestling, rope-dancing, and exhibitions of fireworks.

Laos, Cambodia, Siampa, Cochin-China, Tunquin.—Laos, though surrounded by forests and deserts, is fertile in rice, and furnishes the merchants of Cambodia with excellent benzoin and lacca, musk and rubies, gold and pearls; and the people, in their religion and manners, resemble the Siamese. Cambodia is thinly peopled; the capital, Cambaja, is a mere village of one street, with a single temple; and though the country is fertile in rice and animal food, and abounds in ivory and precious woods, the most peculiar product is gamboge gum, well known to artists for its fine yellow colour. Siampa is a small maritime country, south-east of Cambodia, and its prince is tributary to Cochin-China. Cochin-China presents an extensive range of sea-coast, and is divided into distinct provinces. Both sexes dress alike, in loose robes, with large long sleeves, cotton tunics and trowsers, with a turban on the head, but they walk barefooted; yet the Chinese display not more politeness than the Cochinchians. Tunquin, divided from Cochin-China by a small river, resembles, in its people, territory, and products, the Chinese empire. In the gulf of Tunquin, *tuffons* are frequent and tremendous. They are preceded by very fine weather, a presaging cloud appears in the north-east, black near the horizon, edged with copper colour on the upper part, fading into a glaring white. It often exhibits a ghastly appearance twelve hours before it bursts; its rage lasts many hours from the north-east, attended with dreadful claps of thunder, large and frequent flashes of lightning, and excessive hard rains, when it sinks into a dead calm; after which, it begins again with redoubled rage from the south-west, and continues an equal length of time.

Hindustan.—Hindustan extends from about the 8th to the 35th degree of north latitude, or 1620 geographical miles; and from the 66th to the 92d degree of east longitude, or 1400 geographical miles. The population of this extensive portion of Asia is computed at 60,000,000; and the religion is polytheism; for the doctrine of the Bramins, or priests, teaches belief in a supreme Creator, too ineffable and sublime for human adoration, which is, therefore, addressed to inferior, but great and powerful divinities. This superstition inculcates four casts or orders of the people: 1. The bramin (priest) from the mouth (wisdom) of Brahma, (the supreme;) hence, the priests are supreme:—2. The cheh-teree, from the arms, (strength;) to draw the bow, to fight, to govern: hence, governors, soldiers, &c. a middle class:—3. The brice, from the belly and thighs (nourishment;) to provide the necessaries of life by agriculture and traffic: hence farmers, merchants, &c.—4. The sooder, from the feet, (subjection;) to labour, to serve: hence, the slaves, or day-labourers, &c. The

Hindoos believe in the transmigration of the soul, and therefore abstain from animal food, yet no where on earth are fanatical penances, suicides, and superstitious frenzies, so common. They excel in the manufacture of cotton goods, of metals and ivory, and shawls of Cashmir. The loom in which cotton cloths, or shawls, are woven, is a moveable frame, reared with the rising sun, beneath some shady trees, and transported to its owner's dwelling when the shades of night begin to leave the warp and the woof alike undistinguishable to the craftsmen. The native products are rice, sugar, spices, aromatics, drugs, and precious stones. The climate is diversified by local situation, as is also the aspect of this wide and extensive country; but the periodical rains and intense heats produce luxuriance of vegetation elsewhere unknown, and none can be an indifferent spectator of the variety and richness of the vegetable kingdom of Hindostan. But then the soil is in many places a black mould four feet deep. The chief rivers are the Ganges and the Indus, the Burrampooter, the Sindé, and the Kistna, or sacred stream. The lakes are few, and consist chiefly of Colair, twelve miles north of Masulipatam; Chilka, a salt creek, communicating with the sea, as is also Pulicat; and Cashmir, supposed originally to have been a large lake, still boasts the Oullar, or Tall, fifty-three miles in circuit. The chief mountains are, the southern Tibetan Alps, shrouded in eternal snow, and hence called the Himmala; and the Gauts of Hindostan. Few maps can be relied on respecting the mountains of Hindostan; for in many instances the most recent are copied from the antiquated conjectures of D'Anville. The forests of Hindostan are large and exuberant of vegetation; but the loftiest tree is the palm. The cocoanut tree the most widely diffused; the cotton-tree, the banyan, the teak-tree, and the tamarind, with a numerous botanical collection, which we forbear to mention. The countries on the Ganges are the provinces of Bengal, Bahar, Allahabad, Oude, Agra, with part of Delhi and Agimere, and of Malwa in the south, once the chosen seats of the Mogul power. Bengal, Bahar, with Benares, and some other districts to the west, are in the possession of the British. This extent of territory is not very exactly defined, and the population is, perhaps, not accurately estimated at 11,000,000 of black subjects. The clear revenue has been given at one million and a half; yet the East India Company has not been able to go on without parliamentary interference; and government has a Board of Control to watch over the Company's proceedings. The government of Bengal is vested in a governor-general, who controls also the inferior governments of Madras on the east, and Bombay on the west, with Bencoolen in the island of Sumatra. The British army, supported by the native infantry and cavalry, is now numerous; though the battle of Plassey, which established us in India, in 1757, was won by the invincible army of 900 Europeans; or in the ratio of 1 British soldier to 11½ Hindoos. The chief cities are, Calcutta, the grand capital of British Asia; Patna, the capital of Bahar, 400 miles north-west of Calcutta; Benares, on the northern bank of the Ganges, and 460 miles from Calcutta; Allahabad is the ancient, and Lucknou the present, capital of Oude; Agra, Delhi, and Agimere. The countries on the river Sindé, or Indus, are part of the provinces of Delhi and Agimere, the provinces of Moulton, Lahore, Cashmir, Cabul, Candabar, and Sindi, at the mouth of the Indus. The chief cities are, Lahore, Cashmir, Cabul, Ghisni, Candahar, Moulton, and Tatta. Lahore is the capital of the Seiks, a new religious sect. Cashmir is a filthy place, though the adjacent country is a delicious vale. The central division of Hindostan comprehends the province of Orissa, with part of Golconda, Berar, Dowlahabad, Candeish, Guzerat, and some other districts of inferior note. The Sircars, British provinces, skirt the eastern shore. The chief towns are, Amedabed, the capital of Guzerat, and Cambay, its sea-port; Surat, whose inhabitants are chiefly Moors, Persians, Monguls, and Turks; Bombay, situated on a small but well fortified island, with the isles of Salfatte, and Elephanta; Burhampour, Nagpour, Poona, Masulipatam, and Aurungabad, once the capital of the Deccan. The southern division of Hindostan is called the Deccan, extending from the latitude of Bombay, or 18½ degrees north, to the southern point of Cape Comorin. This part of India nearly contains the whole province of Visiapour, part of Golconda, the central kingdom of

Mysore, the long eastern province of Carnada, or the Carnatic, the principalities of Tanjore, Travancore, and the Samorins of Calicut, the pepper-coast of Canara, and other districts of minor note, with the island of Ceylon. In the Deccan the British power and influence are amazingly extensive; for, besides Madras, and its adjacent territory, the possessions of the East India Company in the south of Hindostan, yield only in extent to those of the north on the Ganges. The chief cities are, Seringapatam, Salem, and Attore, in the east; Dindigul, Coimbatore, and Palicaud, on the south; Paniany, Ferokabad, and Calicut, on the western side; and on the north, Tellicherri, Mangalore, and Carwar. Arcot is the capital of the Carnatic, or of Carnada. Tranquebar is a Danish settlement in Tanjore; Pondicherri was originally a French settlement. Vasco de Gama died at Cochín, on the Malabar coast, in 1525; and Goa is the noted seat of the horrible inquisition. Ceylon is about the size of Ireland, or 260 by 150 miles; and is important chiefly in a commercial view, from its celebrated cinnamon and gums. The religion is the ancient worship of Boodh. The population is not numerous, and the Ceylonese allow to the women a polygamy of the males, as in Tibet. The principal towns are, Kandi in the heart of the island, Colombo, and Trincomali, celebrated chiefly for its harbour. The air is cool and salubrious, and the mountainous districts, in the centre of the island, are covered with prodigious forests, stocked with aromatic trees, and the most odoriferous plants. The soil of the vales is rich, fertile in rice and useful vegetables; and numerous pleasant rivers, and delightful streams, diversify this isolated paradise, swarming with peacocks and other elegant birds. The Mahomedans believe Ceylon to have been the residence of Adam. The Laccadive and Maldive isles are near the coast of Hindostan. The latter, more than 1300 in number, are governed by a chief, called Atoll, and produce cowrie-shells, cocoa-nuts, and fish; the former, thirty in number, trade in cocoa-nuts, fish, and ambergris.

Persia.—Persia may be considered as divided into the eastern and western empires, and the independent provinces, near the Caspian sea. From east to west its length is about 1200 miles, and 1000 broad from north to south. The population is about 10,000,000, of which 6,000,000 are assigned to the western, and 4,000,000 to the eastern empire. The religion is the Mahomedan, but there are still some Parsees, or worshippers of fire, near Baku, and at a place called Gusberabad, near Ispahan. The government is despotic, but its administration in Pandehar, the eastern empire, is extremely mild. The revenue is estimated at 3,000,000*l.* sterling. The provinces are, Georgia, Erivan, Aderbijan, Ghilan, Mazendran, Irac-Ajemi, Chosistan, Fars, or Persia Proper, Kerman, Laristan, Mekran, Segistan, Corasan; Balk and Great Bucharia belong rather to Independent Tartary. Persia is destitute of a navy, though enjoying a great extent of sea-coast; and the maritime commerce is chiefly in the hands of foreigners, because the natives love rather to attend to their studs of horses, and the diversions of the chase, than to improve their own property, or to promote the prosperity of their country. The Persians are polite, hospitable, wise, and sagacious; the men strong and robust, remarkable for cleanliness, but subject to disorders of the eyes. The women are very beautiful; and amidst their abject superstitions we notice chiefly astrology, that proud sophistry, which links the momentary existence of man with the eternal laws of far distant suns and worlds. The chief cities are, Ispahan, the capital; Huraz, celebrated for its delicious climate, and the exquisite salubrity of its atmosphere, perfumed by numerous fragrant flowers, and filled with the divine notes of the bulbul, or oriental nightingale. Tiflis, the capital of Georgia, is famous for its hot springs, and trade in furs; Derbent, on the Caspian sea, is productive of excellent grapes; Erivan, the capital of Persian Armenia, is not far from Mount-Ararat; Tauriz, in Aderbijan, is noted for its bazaars; and Rasht and Sari are the capitals of the Caspian provinces, Ghilan and Mazendran. Persia is famed for its carpets, its embroidery, porcelain, leather, sabres, silk, and bows, the trustiest in all the east. The climate is diversified, but excellent for the human constitution. The most singular feature in the face of the country, is its grand division into two parts, by mountains and deserts; and hence, though the northern provinces are

rich and fertile, those of the south, and even the centre, are unfertile, without extreme care to irrigation. The chief rivers are, the Euphrates and the Tigris, the Divrud and the Gihon, the Zeuderud, which passes by Ispahan, and the Bundamir, between Shirez and Iskakar. The principal lakes are those of Zeré, or Durra, in Segistan; the salt lake of Baktegan, fifty miles east of Shirez, lakes Urmia and Erivan. And the mountains most deserving of notice are, the Caucasus, to the west of Ghilan, and the south of Mazendran; the Persian Gulf chain; the grandest range is south of lake Urmia, where it is joined to the Caucasus; Mount-Ararat; Hetzardara, or the thousand mountains. The forests of Persia abound with deer, bears, boars, lions, tigers, and antelopes; the mountains with wild goats; the numerous wastes swarm with hares, wild asses, and hyænas; and the flocks of large-tailed sheep augment in Erivan. The partridges are large and plentiful, and the pigeons excellent. Among the natural curiosities of Persia, the most remarkable is the inflammable naphtha, or pure rock-oil, found in the neighbourhood of Baku, on the western coast of the Caspian sea. Ormus is the most noted of the Persian isles, though it be now abandoned; and famous chiefly for its salt, which is collected on the rocks, from the spray of the sea, in a fit state for the table. Gombroon, or Kishma, and Karek, are ports of some importance in the Persian Gulf.

Independent Tartary.—This singular region extends from the Caspian sea to the mountains of Belur, or 870 miles east and west; and from the mountains of Gaur in the south, to the Russian boundaries, on the north of the desert of Issim, or about 1500 miles. The chief divisions are, the barren plains in the north, inhabited by the several hordes of Kirguses, called anciently Turkistan; Ilak and Shash, the most northern provinces on the Sihon, are on the south of the Argun mountains; Fregana and Orushna, with the kingdom of Kharizm; south of the Ak-Tau, or white mountains, are the fertile provinces of Sogd, Balk, Kilau, Tokarestan, and Gaur. The chief towns are, Cashgar and Yarcand, Axu and Yulduz, or Karashar, (the black city); Turfan, and Hami, or Camil. The prevailing religion is the Mahomedan. The inhabitants are polite and benevolent Kirguses, about half a million of souls, Bucharians and Kalmuck Tartars, expert in the lance, the sabre, and the bow. The desert of Issim divides the Kirguses from Siberia; and the three great hordes of these people live in tents, leading a wandering life, regarding each other as brethren, rearing vast herds of cattle and horses, and delighting in the chase of wolves, foxes, badgers, antelopes, wild asses, chamois, and tigers. The Kirgusians trade with Russia, supplying annually 150,000 sheep, vast troops of horses, and abundance of wool; and in exchange they receive clothes and furniture, and from Bucharina arms and coats of mail.—Khanrizm, a province of independent Tartary, extends from the Gihon to the Caspian sea, about 350 miles long, by as many broad; its chief town is Khiva. Khiva is seventeen days' journey from the Caspian sea, and thirty-three from Orenburg. The coasts of the Caspian are held by Turkomans in the north, and Uzbeks in the south.—Great Bucharina, the most important part of Independent Tartary, extends 700 miles in length from north to south, and 350 miles in breadth from east to west. The mountains of Argun bound it on the north, the river Armu on the west, and on the south and east, the mountains of Gaur and Belur. The religion is the Mahomedan; the government is despotic; and the Uzbeks and Bucharians are the most spirited and industrious, amidst surrounding barbarians. But the Bucharians never bear arms, though the women of the Uzbeks, surpassing those of the other Tartars in beauty, fail not to follow their lords to the field of battle. The provinces of Great Bucharina are, Fergana, Andegan, Sogd, Kottan and Kilan, Tokarestan, and Gaur. And the chief cities are, Samarkand, Bokhara, Balk, Zouf, or Gaur, Badakshan, and Kotlan. Samarkand was famous for its manufacture of silk paper, as early as A.D. 650; Bokhara, for its finelinen, was distinguished even in the tenth century; Balk, for its beautiful silks; Gaur, for its rich quarries of lapis lazuli; and Badakshan, included in the Belur-Alps, was used as a state-prison, for rivals, or insurgents, against the khan of Great Bucharina. Situated in the parallel of Spain and Greece, the climate of Bucharina is excellent. The soil adjacent to the rivers is fertile, but neglected.

The chief rivers are, the Armu, and Sirr, or Shash; the island seas are the seas of Aral and Baikal, and the lakes are those of Tengis and Balkash; and the chief mountains are those of Belur, of Gaur, the Hindoo-Kob, of Argun, of Kara-Tau, and Ak-Tau. Ebu Haukal says, all the families of Independent Tartary are but one house; and, in Sogd, he saw a great building, whose doors were fastened back with nails against the walls, continuing thus open night and day, for above 100 years, that strangers, who should arrive at the most unseasonable hours, might find no obstacle to enter, and receive every thing necessary both for man and beast.

Arabia.—Arabia, bounded by the Red Sea, the Indian Ocean, and the Persian Gulf, on the west, south, and east, and on the north by the Mediterranean and Palestine, is about 1800 miles from north to south, and 800 broad. The centre of Arabia is a vast desert. The provinces situated on the sea-coast are fertile in millet, barley, beans, lentils, rape, sugar-cane, tobacco, cotton, valuable spices, pomegranates, melons, and coffee. The religion is the Mahomedan, but a new sect, called Wahabees, has made considerable progress. This sect has derived its name from one Abdul Wahab, a sheik, or imam, in the province of El-Ared. A sheik (old man) is a governor of a province, and an imam (vicar) is an ecclesiastical ruler, as the twelve imams, the genuine successors of Mahomet, in Persia. In Arabia, an imam is a calif, or prince of the faithful. The Arabians are polite and hospitable, temperate in eating, and abstemious of wine. The women dye their nails of a scarlet colour, their feet and hands of a yellowish brown, and no art is left unemployed to make the eye-brows large and black. Many of the poorest people read and write, as education is attended to very generally, and the chief cities are celebrated for colleges and academies. The holy cities are Mecca and Medina. Gedda, a sea-port, forty miles distant from Mecca, was famous in ancient times, when the markets of Saana and Merab, and the harbours of Oman and Aden, received the precious cargoes of aromatics brought thither by the hardy camels of the Koreishites. Now, Mecca, the birth-place of Mahomet, is governed by a sherif, who is a temporal prince; and Medina, 200 miles north of Mecca, contains the tomb of the prophet. Sana, in Yemen, at the foot of a mountain called Nikkum, about four miles in circuit, is now the chief city of Arabia. Mocha is noted for its having one glass-house. The chief rivers are, the Euphrates and the Tigris, flowing through Irak-Arabia; and the chief range of mountains proceeds in the direction of the Red Sea, while the hills of Omon are merely a continuation of those on the other side of the Persian Gulf. Mount-Sinai is in Arabia-Petræa; and in the country of Seger there is a range of hills famous for producing frankincense. The horses of Arabia have long been celebrated; and the Kochlani breed are direct from the stalls of Solomon. But the chief animal is the camel, the ship of the desert. And the woods of Yemen abound in numerous monkeys; the jerboa, or rat of Pharaoh, is found in Neget; and wherever the mountains originate springs, to scatter verdure and fragrance, the antelope is there; and the wild oxen, wolves, foxes, and boars, pasture the woods, or prey on their inmates. The islands belonging to Arabia, are Socotra, in the Arabian Gulf, or Red Sea, about 240 miles from the southern coast, and celebrated for its aloes; and the isle of Bahrin, in the Persian Gulf, noted for its productive pearl fishery.

The Asiatic Islands.—These islands comprise those of the oriental archipelago; Australasia, and Polynesia. In the archipelago are the islands of Sunda, or the Sumatran chain, comprising Sumatra, Java, Balli, Lombok, Sumbava, Flores, and Timor. Sumatra, 950 miles long, and 200 broad, has an English settlement at Bencoolen. Though frost, snow, and hail, be unknown, the inland inhabitants of the mountainous districts use fire to dispel the cold; for true it is that a man may be frozen to death in the torrid zone. But these inland races are savages, covered with red hair, and little superior to the orang-outangs of Borneo. The elephant, the rhinoceros, the hippopotamus, the tiger, the bear, the otter, the porcupine, the wild hog, and the civet cat; herds of deer and troops of monkeys; wild poultry, the Argus pheasant, and swarms of destructive termites, comprise part of its zoology. Java, 650 miles long by 100 broad, is well known for its Dutch capital,

Batavia, which is, in fact, the metropolis of the eastern archipelago. But Java is an unhealthy place, and "of three settlers it is rare that one outlives the year;" yet, to Batavia, Europeans and Chinese resort, the latter being contented, for the sake of gain, to forget the tombs of their ancestors, and the laws of Confucius, which interdict emigration. Balli furnishes slaves and cotton, the others spices; and the people of Timor are the bravest of these Oriental islanders.—Borneo, except New Holland, is the largest island in the world, being 900 miles in length, by 600 in breadth. The coasts are possessed by Malays, Moors, Macassars, from Celebez, and even Japanese. The natives in the interior are blacks, called Biajos, with lanky hair, of middle size, feeble, and inactive. Thousands of ourang-outangs are seen amidst the swamps and forests of this island. A knight of Borneo is known by his string of tigers' teeth, a chief of a tribe by having two of his front teeth replaced by two gold teeth. The capital of the island consists of 3000 houses built on posts, fixed in rafts, which are moored to the shore, and may be moved from place to place, according to the convenience or the caprice of the owners. The Manillas, or Philippine islands, occupy a space of 20° of latitude, in the longitude of 120° and 130° east of Greenwich; and form a north-eastern frontier to the island of Borneo. Luzon, the largest of these islands, is 500 miles long, and 100 broad; and its chief city, Manilla, boasts a population of 12,000 Christians, mostly Spaniards. For it was between this island and Acapulco, that the Spanish galleons carried on their celebrated commerce, through a space of 8,400 miles of the ocean.—Mindanao is mountainous, but the vales are rich, being watered by numerous crystalline rivulets; and horses and buffaloes swarm in the interior. The remaining Philippine islands are, Pulawain, Mindoro, Pani, Buglas, or the Isle of Negroes, Zebu, or Leita, and Samar. Maetan, a small isle, on the east of Zebu, is the place where the celebrated navigator, Magellan, was slain. These islands present many volcanic appearances; such as lava, volcanic glass, sulphur, and hot springs; and the bread-fruit extends its beneficial arms to the hundreds of islands that sprinkle the Indian and Pacific oceans.—The Celebebian Group, or the isles of Poison, are Celebez, Sanguy, Shullas, Peling, Boutan, and Sala. Celebez is 600 miles long, and about 60 broad, considering the extensive bays that chequer its coast. In its centre there are several live volcanoes. From the mountains, rivers precipitate themselves over vast rocks. The natives are called Macassars, and are famed most for their pusillanimous attacks on solitary vessels, with lances and arrows, poisoned with the juice of the deadly upas. Though these islands produce spices and rice, their botany is full of poisonous trees and plants.—The Moluccas are, Ternah, Tidore, Motir, Makian, and Bakian. Ternah is the retreat of the kingfisher, clothed in scarlet and mazarine blue; Tidore boasts five-and-twenty mosques, and its sultan claims tribute of Gilolo; Motir is the seat of Venus and voluptuousness; Makian rises out of the sea like a sugar-loaf; and Bakian is famed for its prodigious rocks of coral, of infinite variety and beauty.—The Spice Islands, are Gilolo, Ceram, Bouro, Mortay, Oubi, Mysol, Amboyna, and Banda. Gilolo, once governed by a sheref from Mecca, proves how far the Mahomedan conquests had extended. The natives are good weavers, and have plenty of oxen, buffaloes, goats, deer, and wild hogs, with bread-fruit and sago trees. Ceram abounds in clove trees, and large forests of sago trees; Bouro possesses the civet weasel, green-ebony, iron-wood, &c.; Mortay is full of sago trees; Mysol of birds of paradise; Oubi produces cloves; Amboyna boasts of a population of 17,800 Dutch Protestants; and 27,000 Mahomedans, Chinese, and savages. The clove tree in this island grows to the amazing height of forty or fifty feet, and will yield thirty pounds weight annually. But Banda is the chief isle in this group, furnishing 160,000 pounds weight of nutmegs, and 46,000 pounds of mace annually. The nutmeg tree grows to the size of the pear tree in our orchards; its leaves resemble those of the laurel; and from the age of 10 to 100 years it bears fruit. The nutmeg, on the tree, is about the size and colour of an apricot, but shaped like a pear. When ripe, the rind bursts, and discovers the mace, of a deep red, covering in part the thin shell of the nutmeg.

Australasia.—Australasia contains New Holland, Papua, or New Guinea, New Britain, and New Ireland, with the Solomon Isles; New Caledonia, and the New Hebrides, New Zealand; and Van Diemen's Land. New Holland is the largest island in the world, and some progress is now making in exploring its interior. From east to west it is 2,730 miles over; and from north to south 1,960 miles. The original inhabitants are harmless savages, grossly ignorant, believing in magic, witchcraft, and ghosts! At Port Jackson a colony has been formed for British convicts; but numerous free settlers are now established on the island, and it will, ere long, be famous, since the breed of sheep there rivals the Spanish Merinos, and the soil is excellent for grain. Papua, or New Guinea, partakes of the opulence of the Moluccas, with their singular varieties of plants and animals. And in the interior a race of savages, called Haraforas, live in trees, which they ascend by a notched pole, drawing it after them, to prevent surprise. The women are industrious, the men indolent, but fond of ornaments, as the tusks of boars around their necks, and feathers of the bird of paradise stuck in their woolly hair. Papua is the chosen abode of that splendid bird, of elegant parrots, and the crowned gigantic pigeon, nearly as big as a Norfolk turkey. New Britain resembles Papua in its inhabitants and products. The canoes of New Ireland are ninety feet long, formed out of single trees; and the inhabitants of the Solomon isles ornament their necks with gold beads. New-Caledonia, and the New Hebrides, have more intelligent inhabitants than we have lately been among, for their houses have carved door-posts, and the women are more chaste than in the other isles of the Pacific. Plantains, sugar-canes, yams, and several kinds of fruit-trees, are found in the Hebrides, whose natives are very dexterous in launching the spear, with unerring certainty. New Zealand consists of two large islands, which enjoy a temperate climate, equal to that of France; and the people believe that, the third day after they inter their dead, the heart is separated from the body, and carried to the clouds by an attendant spirit. Van Diemen's Land, an island situated south of New Holland, is about 160 miles long, and 80 broad. The natives and the products resemble those of New Zealand and New Holland.

Polynesia.—Polynesia is divided into the following islands, or groups.—The Pellew Islands, inhabited by a gentle and amiable race of industrious savages; the gay and innocent children of nature, united in one large family, by that concentration of society which small islands impose on their natives. The Ladrões, or Marians, of which the largest are Guam and Tinian, are inhabited by a people who resemble the natives of the Philippines. These islands are fourteen in number, but only three are inhabited. North of the Ladrões are many small islands, with a few scattered islands on the north of the Carolines, that have not been classed and named. The Carolines, about thirty in number, are very populous, and the natives, like those of the Philippines, live chiefly upon fish and cocoa-nuts. The three principal of these islands are, Hogoleu, Yap, and Ulea. The Sandwich Isles were discovered by Captain Cook, at the chief of which, Owhyhee, he lost his life. The inhabitants are mild, affable, and ingenious, but human sacrifices are frequent. The climate is more temperate than that of the West Indies. Dogs, hogs, and rats, are the native quadrupeds. The birds are pigeons, plovers, owls, and ravens. The bread-fruit tree abounds, and sugar-canes grow to an amazing size. The Marquesas boast no island half so large as Otaheite. Noabeva, the chief island of the Marquesas, is only about sixty miles in circumference. The natives possess the most exquisite symmetry of shape and regularity of features, and the women are as fair as the females in Italy and Spain; but mutual slaughter and human sacrifices prevail. The Society Islands amount to about seventy in number, of which Otaheite is the chief, being about 120 miles in circumference. The men are olive-coloured, the women brunettes, with fine black eyes, white and even teeth, soft skin, elegant limbs, jet-black hair, perfumed, and ornamented with flowers; but still they are inferior in beauty to the women of the Marquesas; nor do any of the females of the South-sea islands possess the Grecian forms and academical precision of feminine beauty. But the Otaheiteans are the Italians of the Great Pacific

Ocean in language and politeness, and in the romantic scenery of their country. Infants swim as soon as they can walk. The Friendly Islands, including the Feejee isles, the Navigators' islands, and several more northerly and detached isles, are peopled by men of grave and regular behaviour, who are governed by despotic chiefs. The largest of these islands are, Pola, Tongataboo, Oyolava, Maouna, and Opoun. Provisions are amazingly plentiful in these islands. The men are of great stature, the women pretty and licentious. The inhabitants of all Australasia and Polynesia do not, perhaps, amount to 300,000 souls. The speech diffused throughout all the scattered islands of Polynesia is derived from the Malayan. The trees and plants peculiar to the tropical Pacific islands, are the bread-fruit tree, the plantain, the cocoa, the sugar-cane, figs, sweet potatoes, &c.

ASILUS, hornet fly.

ASPALATHUS, African broom.

ASPARAGUS, or *Sparrow Grass*, one of the greatest delicacies which our kitchen-garden affords, being particularly estimable from the early season at which it is produced. The asparagus is raised from seed, in beds formed for the purpose; and the plants should remain three years in the ground before they are cut; after which, for a dozen years, they will continue to afford a regular crop. In the Editor's garden there are some very fine beds about twenty years old.

ASPECT, the situation of the planets with respect to each other; there are 5 aspects: 1st, Sextile, marked  $\ast$ , when the planets are  $60^\circ$  distant; 2dly, Quartile  $\square$ , at  $90^\circ$ ; 3dly, Trine, when  $120^\circ$   $\Delta$ ; 4thly, Opposition  $\circ$ , when  $180^\circ$ ; and 5thly, Conjunction  $\circ$ , when both in the same degree.

ASPEN TREE, the trembling poplar, flourishes in any situation; the wood, though good for packsaddles, milk pails, clogs, and wood-work for pattens, is very bad for beds, as it promotes insects.

ASPERIFOLIOUS, in Botany, one of the divisions or classes of plants in the Linnean system; so denominated because they are usually rough-leaved.

ASPERUGO, small wild bugloss.

ASPERULA, woodroof.

ASPHALTUM, bitumen Indiacum, pitch formed on the surface of the Dead Sea, and which was formerly employed in embalming the bodies of the dead.

ASPHODELUS, king's spear, asphodel.

ASS, a species of aëquus, or horse. When very young, the ass is sprightly, and even tolerably handsome; but he soon loses these qualities, and becomes dull, stupid, and headstrong. But he is not equally stupid in all countries; for in Spain, and some other countries, he is much more elegant and tractable; and if treated with care, there is no doubt that he might be rendered much more serviceable to us than he now is. Wild asses are fierce, swift, and formidable, and, when pursued, will defend themselves with courage.

ASSA-FŒTIDA, the concrete juice or resinous gum of a large umbelliferous plant, growing in India and Persia. The Banian Indians use it in all their dishes; our own cooks substitute it for garlic. In Arabia and Persia it is used both internally and externally as a medicine. It is an excellent cure for the whooping cough and for worms; in flatulent colics, &c.

ASSAULT, an attempt to offer to beat another without touching him; as if one lifts up his cane, a whip, or his fist, to hit another, or strikes at him, but misses him. The party injured may have redress by action of trespass *vi et armis*, wherein he shall receive damages as a compensation for injury. This teaches society the exterior formula of good breeding; but the temperament of an Englishman pricks him to repel force by force; and to repay by an eye for an eye, or a tooth for a tooth, without trusting to the doubtful issue of trespass, *per togam pecuniamque*.

ASSAYING. There are two kinds of assaying; one before metals are melted, the other after they have been struck; the first brings them to their proper fineness, and the last compares them with the standard. For the first assayers take 14 or 15 grains of gold, and half a drachm of silver, if it be for money; and 18 grains of the one, and a drachm of the other, if for other uses. The second assay is made of one of the pieces of money, which is cut into four parts. The quantity of gold for an assay

is here six grains. Assaying is also the particular mode of examining every ore and mixed metal, according to its nature, with the proper fluxes, to discover not only what metals, with their proportions, are contained in ores, but also the quantity of sulphur, vitriol, alum, arsenic, and other matters. Gold is obtained pure by dissolving it in nitro-muriatic acid, and precipitating the metal by dropping in a diluted solution of sulphate of iron: the powder which precipitates is pure gold. Silver is obtained pure by dissolving it in nitric acid, and precipitating it with a diluted solution of sulphate of iron. With metallurgists the mass consists of 24 imaginary parts, called carats. Gold of 24 carats means pure gold: the number of carats mentioned specifies the parts of pure gold, and what that number wants of 24 carats, indicates the quantity of base metal in the alloy. Gold of 12 carats, means 12 parts of gold and 12 of another metal. Gold coins of Great Britain are of 22 carats fine; they contain, therefore, 11 parts of gold and one of copper. *Parting* is the separation of gold from silver, when both are contained in an alloy; and it is founded on the insolubility of gold, and the solubility of silver in nitric acid.

Fig. 108.

ASSAY BALANCE, is of very little different construction from the common scales, having a beam from 10 to 12 inches, and being made of the best steel. The beam is suspended in a fork, and as the balance will hardly stand still in the open air, it must be put into a case, as represented in the figure. A pair of pincers are used to put articles to be weighed into this balance; or if the article be a powder, a small shovel or spoon.

ASSIZE, an assembly of knights, and other substantial men, together with a justice, in a certain place, and at a certain time, when and where the writs, processes, whether civil or criminal, are decided by a jury, directed by a judge. If a man has been charged with an offence, before he can be put on his trial, the charge must first be examined by an impartial grand jury of 23 persons; twelve of whom, at least, must agree to find a bill of indictment, which being found, he then undergoes a public trial before twelve of his equals. The powers of a grand jury are most extensive, and their duties being most important, it is necessary that they be performed with the greatest care, intelligence, and impartiality. Bills ought never to be found lightly, on frivolous pretences, or imperfect evidence; and as grand juries only hear the evidence of the prosecutor, they ought to be vigilantly on their guard against trifling, vexatious, and malicious prosecutions. The petit jury of twelve make oath, that "they shall well and truly try, and true deliverance make, between the king and the prisoner at the bar, according to the evidence." After they have fully heard the evidence, the prisoner's defence, and the law from the judge, the twelve must decide each for himself, and the whole must be unanimous in acquitting, or in condemning, the prisoner. The jury must be impartial and independent, or they are liable to be challenged or objected to. They should also found their verdict on *their own* judgment, deducing it from clear and positive evidence: no other duty being so sacred, and no other trust so great, as that reposed in the integrity and independence of a jurymen.

ASSOCIATION OF IDEAS, is when two or more ideas constantly and immediately follow or succeed one another in the mind, so that one shall constantly and infallibly succeed another. The influence of association in regulating the succession of our thoughts, is a fact familiar to all men: that one thought is often suggested to the mind by another, and that the sight of an external object often recalls former occurrences, and revives former feelings, are indisputable facts. This subject is very fully treated in the Editor's Grammar of Logic and Intellectual Philosophy. See chap. vii. book ii. of that work, second edition.

ASSUMPSIT, in Law, a voluntary or verbal promise, whereby a person assumes, or takes upon him, to pay any thing to another. There are numerous cases of assumpsit on record.

Thus all notes of hand, bills of exchange, &c. come under this name; and so of many other covenants, verbal or written.

**ASSUMPTIVE ARMS**, in Heraldry. Thus, if a soldier, who has no right by blood to arms, or if he have none, shall in war captivate any gentleman, nobleman, or prince, he may then assume the arms of his prisoner, and enjoy them in his heirs for ever.

**ASSURANCE ON LIVES**. By assuring a life, is meant obtaining security for a sum to be received, should the life drop, in consideration of such a payment made to the assurer, as shall be a sufficient compensation for the loss and hazard to which he exposes himself. In estimating this compensation, the amount of it will depend entirely on the rate of interest at which money is improved, and the probable duration of the life of the individual. In order to illustrate this, let £100 be supposed to be assured on a life for a year to come, supposing money to bear an interest of 5 per cent. Now, first, if it were certain that the life would become extinct in the course of the year, the premium would be the present value of £100, payable a year hence, which at 5 per cent. would be £95. 4s. 8d.; but if, instead of the certain extinction of the life, it be known from the regular bills of mortality, that out of 1000 persons of the age of the assured, only 250 fall in the course of a year, or

which is the same, if  $\frac{250}{1000}$ , or  $\frac{1}{4}$ , represent the prospect of its

failing, then  $\frac{3}{4}$  of the above premium will be the fair compensation to be received by the assurer: and as there have been tables of the decrease of human life kept for many years, in various parts of this and other kingdoms, the calculation of the fair premium to be paid for any age, for a year, is extremely simple, and needs no farther illustration. But the assurances most commonly practised, are those on single lives, either for a given term, or during their whole continuance; and the premium is either paid in a single present payment, or in annual payments during the said term, or till the life fails; in both which cases the calculation becomes more complicated. On the most equitable principles, tables have been computed which exhibit at one view the annual payment that ought to be made to assure a life, at any age, for £100; and which, therefore, is equally applicable for any other sum, by a simple operation of multiplication and division; these annual payments vary a little in different offices, but the most general terms and conditions are as follows:—The person making the assurance is to declare the place and date of birth of the person whose life is to be assured; whether he have had the small-pox; whether subject to the gout; and whether in the army or navy.

**Conditions of Assurance made by Persons on their own Lives**.—The assurance to be void, if the person whose life is assured shall depart beyond the limits of Europe, shall die upon the seas, (except in his majesty's packets passing between Great Britain and Ireland,) or shall enter into or engage in any military or naval service whatever, without the previous consent of the company; or shall die by suicide, duelling, or the hand of justice; or shall not be, at the time the assurance is made, in good health.

**Conditions of Assurance made by Persons on the Lives of others**.—The assurance to be void, if the person whose life is assured shall depart beyond the limits of Europe, shall die upon the seas, (except in his majesty's packets passing between Great Britain and Ireland,) or shall enter into, or engage in any military or naval service whatever, without the previous consent of the company; or shall not be, at the time the assurance is made, in good health. These rules are varied conditionally in some assurance offices; but we have exhibited the general principles. Any person making an assurance on the life of another, must be interested therein, agreeably to act of 14th of Geo. III. chap. 48, which prohibits wagering, or speculative insurances.

Since the foregoing was written for this work, some new assurance associations have arisen, which take numerous risks that the old offices would not assure; and it matters not now, whether a man belong to the army, the navy, or any other service equally hazardous: he may assure at some of these new offices with as much facility as a tradesman could do at the Sun, the Equitable, or the Rock life-assurance offices.

## TABLE OF PREMIUMS

*For Assuring the Sum of One Hundred Pounds upon the Life of any healthy Person, from the Age of Eight to Sixty-seven.*

| Age. | One Year. | 7 Yrs. at an ann. payment of | The whole Life, at an annual payment of | Age. | One Year. | 7 Yrs. at an ann. payment of | The whole Life, at an annual payment of |
|------|-----------|------------------------------|-----------------------------------------|------|-----------|------------------------------|-----------------------------------------|
| 8 to | £. s. d.  | £. s. d.                     | £. s. d.                                | 8 to | £. s. d.  | £. s. d.                     | £. s. d.                                |
| 14   | 0 17 9    | 1 1 5                        | 1 17 7                                  | 41   | 2 2 0     | 2 5 4                        | 3 9 9                                   |

**ASTER**, in Botany, starwort, so called as having a radiated flower.

**ASTERIA**, the goshawk; also the gem cat's eye: the name also of an extraneous fossil, known as star-stone.

**ASTERIAS**, the star fish, or sea star.

**ASTERION** and **CHARA**, or *Canes Venatici*, the Greyhounds. This constellation was introduced by Hevelius. It occupies the western space between Boötes and the hind legs of Ursa Major, and is easily distinguished by a star of the 3d magnitude on the neck of Chara, forming a triangle with  $\gamma$  and  $\eta$ , in the hip and tail of Ursa Major. Sir Charles Scarborough, physician to Charles II. called this star *Cor Caroli*, or Charles's Heart, in honour of king Charles I.

**A-STERN**, denotes any distance behind a ship, as opposed to **A-HEAD**.

**ASTRAGAL**, in Architecture, a round moulding, which, in the orders, surrounds the top of the shaft or body of the column; it is used also at the bottoms as well as the tops of columns; and properly represents a ring on whatever part of a column it is placed.—In Anatomy, the upper bone of the tarsus, which, by its conjunction with the bones of the leg, forms the ankle-joint.

**ASTRAGALUS**, milk, or liquorice vetch.

**ASTRANTIA**, masterwort.

**ASTRINGENTS**, in Medicine, are distinguished by a rough austere taste, and the property of changing solutions of iron, especially those made in the vitriolic acid, into a dark purple or black colour; such as galls, tormentil root, terra japonica, acacia, &c.

**ASTROITES**, star stone.

**ASTROLABE**, a stereographic projection of the sphere, which, among the ancients, was equivalent to the armillary sphere, or armed by proper graduations, &c. it enabled an observer to take the altitude of the sun, or of a star.

**ASTROLOGY**, a conjectural science, founded upon certain supposed effects, influences, positions, and situations of the stars, with a view to predict future events from their aspects, &c. It surprises one, that our almanack makers should still repeat the nonsensical stuff of Lilly, Moore, and other clever

men, who reigned in the ages of judicial, perhaps natural, astrology.

**ASTRONOMY**, the science which teaches the motions of the Earth, the Sun, Moon, Planets, Comets, and Stars, and explains the phenomena occasioned by those motions, is divided into two parts: 1st. that which treats of the motions, magnitudes, and periods of the revolutions of the heavenly bodies, and is called *pure* or *plain Astronomy*; 2d. that which investigates the causes and laws by which these motions are regulated. The student of astronomy may, in the day time, observe one of the chief of these motions in the rising, ascent, exaltation, declension, and setting of the sun. In the morning he will see it rise in the eastern heavens, ascend in this hemisphere towards the south, attain its greatest height at noon, and then descend again, till it sets in the west, as far from the south as it rose in the morning. This is the *first* practical lesson in astronomy. In the night time he may observe the stars rise in the east, ascend towards the south, and decline and set to the west; and this will be the *second* lesson. He may, however, observe, that one star, *viz.* that over the North Pole, never moves, and that all the others move around it, and those within a certain distance never set; and, in short, in this *third* lesson, which is worthy of being pursued through successive evenings, he will become master of the general motions of the heavens. Thus, by measuring, for example, at London, during a long winter's night, the two meridian heights of the Polar Star, (*α Ursæ Minoris*, having  $88^{\circ} 20' 49''$  declination N.) we find that (ann. 1820)

|                                                                 |                       |
|-----------------------------------------------------------------|-----------------------|
| When it passes above the Pole, its altitude }<br>measures ..... | $53^{\circ} 10' 11''$ |
| And when it passes below the Pole, it }<br>measures .....       | $49^{\circ} 51' 49''$ |

|                           |                        |
|---------------------------|------------------------|
| The sum of which is ..... | $103^{\circ} 02' 00''$ |
| And their half .....      | $51^{\circ} 31' 00''$  |

Which will be the altitude of the Pole above the horizon of London, or the distance of this city from the equator. If, on the contrary, we subtract  $49^{\circ} 51' 49''$  from  $53^{\circ} 10' 11''$ , we shall find for their difference  $3^{\circ} 18' 22''$ , of which the half,  $1^{\circ} 39' 11''$ , will give the distance of the Polar Star from the Pole (in 1820), which we thus find does not exactly occupy this point, but is yet very near to it. He will observe, in a *fourth* lesson, which is also to be pursued through successive nights, that the moon changes her place with regard to the stars, that she increases in light in proportion to her increased distance from the sun, till she arrives at the opposite, or rises as the sun sets; and that the light increases on one side, and decreases on the other, being always towards the sun. He will, in like manner, observe, that the planets change their motions slowly in regard to the fixed stars, and that both the moon and the planets move in the same line, or nearly so, among the fixed stars; and this *fifth* lesson may be mixed with others through successive weeks. He will be highly gratified by applying any telescope (the larger the better, but the smallest will afford much gratification) to the moon, planets, and stars. He will observe the decrease and increase, and change of the shadows of the moon's pits; the satellites of Jupiter; the moon-like appearance of Venus; the ring and moons of Saturn; and many of the constellations and nebulous clusters of stars.

The heavenly bodies that we are to notice, are, the *Sun*, the *Planets*, *Comets*, and *Fixed Stars*.

The Sun gives name to the system of Astronomy, which Copernicus, Kepler, and Newton have established, but which was known in the East 4000 years ago, in its general appearances, as perfectly as by La Place in our own times. The solar system is so called, because the Sun is supposed to be situated in a certain point, termed the centre of the system, having all the planets revolving round him at different distances, and in different periods of time. This is likewise called the Copernican system. See *Plate Solar System*.

The **SUN**, situated near the centre of the orbits of all the planets, revolves on its axis in 25 days 14 hours 4 minutes. This revolution is determined from the motion of the spots on its surface, which first make their appearance on the eastern extremity, and then by degrees come forwards towards the middle, and so pass on till they reach the western

edge, and then disappear. When they have been absent for nearly the same period of time which they were visible, they appear again as at first, finishing their entire circuit in 27 days 12 hours 20 minutes.\* The Sun is likewise agitated by a small motion round the centre of gravity of the solar system, occasioned by the various attractions of the surrounding planets; but as this centre of gravity is generally within the body of the Sun, and can never be at the distance of more than the length of the solar diameter from the centre of that body, astronomers generally consider the Sun as the centre of the system, round which all the planets revolve; though in reality the centre of gravity of the Sun, and of all the planets, is the *centre of the world*. As the Sun revolves on an axis, his figure is supposed not to be strictly in the form of a globe, but a little flattened at the poles; and that his axis makes an angle of about eight degrees, with a perpendicular to the plane of the earth's orbit. As the Sun's apparent diameter is longer in December than in June, it follows that the Sun is nearer to the earth in our winter than it is in summer; for the apparent magnitude of a distant body diminishes as the distance increases. The mean apparent diameter of the Sun is stated to be  $32' 2''$ ; hence, taking the distance of the Sun from the earth to be 95 millions of miles, as is now determined, its real diameter will be 886,149 miles; and, as the magnitudes of all spherical bodies are as the cubes of their diameters, the magnitude of the Sun will be 1,377,613 times that of the earth; the diameter of the earth being 7964 miles, the diameter of the Sun is above 111 times the diameter of the earth. When we consider the Sun as the fountain of light that illuminates this universe, and that causes the earth to produce every thing desirable for man, may we not consider it also as an eminent, large, and lucid planet, evidently the primary one of our system; Mercury, Venus, the Earth, and all the others, being its secondaries? And considering its solidity, its atmosphere and diversified surface, its rotation on its axis, and all the circumstances attending this glorious globe, may we not conclude that it is inhabited, like the other planets, by beings whose organs are adapted to the physical properties of the Sun. This seems to be a more pleasing and agreeable way of making the tour of creation, than joining issue with fanciful poets, who have pronounced it the abode of blessed spirits; or closing with the chilling doctrines of angry moralists, who have fancied it the fittest residence for the punishment or purgation of the wicked from off the earth.

The **PLANETS**.—There are eleven planets belonging to our system. Six of these have been recognized from time immemorial: namely, Mercury, Venus, the Earth, Mars, Jupiter, and Saturn. But the remaining five, invisible to the naked eye, have lately been discovered by the help of the telescope; and are therefore called *telescopic planets*: namely,

| Vesta.....            | M. Olbers,... March 29, 1807.  |

All these Planets revolve round the sun, as the centre of motion; and in performing their revolutions they follow the laws of planetary motion discovered by Kepler, and confirmed by subsequent observations. These laws are, The orbit of each planet is an ellipse; of which the sun occupies one of the foci. That focus is called the lower focus. If we suppose the plane of the earth's orbit, which passes through the centre of the sun, to be extended in every direction, as far as the fixed stars, it will mark out a great circle among them, which is the ecliptic; and with this the situations of the orbits of all the other planets are compared. The planes of the orbits of all the other Planets must necessarily pass through the centre of the sun, but if extended as far as the fixed stars, they form circles different from each other, as also from the ecliptic; one

\* M. Cassini determined the time which the Sun takes to revolve on its axis, thus: the time in which a spot returns to the same situation on the Sun's disc, (determined from a series of accurate observations,) is 27 days 12 hours 20 minutes; now the mean motion of the earth in that time is  $27^{\circ} 7' 8''$ ; hence  $360^{\circ} + 27^{\circ} 7' 8'' = 27d. 12h. 20m. : 360^{\circ} = 25d. 14h. 4m.$  the time of rotation.

part of each orbit, is on the north, and the other on the south side of the ecliptic. Therefore the orbit of each planet cuts the ecliptic in two opposite points, as A B, fig. 110, which are called the *nodes* of that particular planet; and the nodes of one planet cut the ecliptic in planes different from the nodes of another planet. The line A B is called the line of the nodes. The ascending node is that where the planet passes from the south to the north side of the ecliptic. The angle E G is the inclination of the planes of the two orbits to each other. The descending node, that where the planet passes from the north to the south side of the ecliptic. Perigee, when the sun and moon are nearest the earth; apogee, when at their greatest distance. The extremity of the major axis of this ellipse, nearest the sun, is called the perihelion; the opposite extremity of the same axis is called the aphelion. The line, which joins these two points, is called the line of the apsides. The radius vector is an imaginary line drawn from the centre of the sun to the centre of the planet, in any part of its orbit. The velocity of a planet in its orbit is always greatest at its perihelion. This velocity diminishes as the radius vector increases, till the planet arrives at its aphelion, when its motion is the slowest. It then increases in an inverse manner, till the planet arrives again at its perihelion. The areas, described about the sun by the radius vector of the planet, are proportional to the times employed in describing them; and these laws are sufficient for determining the motion of the planets round the sun; but it is necessary to know, for each of these planets, seven quantities; which are called the elements of their elliptical motion. The first five of these elements relate to the motion in an ellipse; the last two relate to the position of the orbit, since the planets do not all move in the same plane; agreeably to the following tables of La Place, calculated for the commencement of the present century.

#### 1. Duration of the Sidereal Revolution.

| Days.                 | Days.                   |
|-----------------------|-------------------------|
| Mercury ..... 87·929+ | Ceres ..... 1681·539+   |
| Venus ..... 224·700+  | Pallas ..... 1681·709+  |
| Earth ..... 365·256+  | Jupiter ..... 4332·569+ |
| Mars ..... 386·979+   | Saturn ..... 10758·969+ |
| Vesta ..... 1335·205+ | Uranus ..... 30689·712+ |
| Juno ..... 1590·998+  |                         |

#### 2. The Mean Distance of the Planets from the Sun.

|                       |                         |
|-----------------------|-------------------------|
| Mercury ..... 3870381 | Ceres ..... 2·7674060   |
| Venus ..... 7233323   | Pallas ..... 2·7675920  |
| Earth ..... 1·0000000 | Jupiter ..... 5·2027911 |

| Juno ..... 59 2349     |                       |

#### 6. Longitude of the Ascending Node.

|                        |                        |
|------------------------|------------------------|
| Mercury ..... 51° 0651 | Ceres ..... 89° 9083   |
| Venus ..... 83 1972    | Pallas ..... 191 7148  |
| Earth ..... 0 0000     | Jupiter ..... 109 3624 |
| Mars ..... 53 3605     | Saturn ..... 124 3662  |
| Vesta ..... 114 4630   | Uranus ..... 80 9488   |
| Juno ..... 190 1228    |                        |

#### 7. Inclination of the Orbit to the Ecliptic.

|                        |                       |
|------------------------|-----------------------|
| Mercury ..... 7° 78058 | Ceres ..... 11° 80680 |
| Venus ..... 3 76936    | Pallas ..... 38 46540 |
| Earth ..... 0 00000    | Jupiter ..... 1 46034 |
| Mars ..... 2 05663     | Saturn ..... 2 77102  |
| Vesta ..... 7 94010    | Uranus ..... 0 85990  |
| Juno ..... 14 50860    |                       |

The examination of the first two tables will shew us, that the duration of the revolutions of the planets increases with their mean distance from the sun. Whence Kepler discovered his third fundamental law; namely, The squares of the times of the revolutions of the Planets are to each other as the cubes of their mean distances. But then the ellipses which the Planets describe, are not unalterable: their major axes are the same; but their eccentricities, the positions of their perihelion nodes, with the inclination of their orbits to the ecliptic, seem to vary in a course of years.

*Mercury* ☿, the least of the inferior planets, and yet nearest to the sun, is 36,814,721 miles from that luminary. This planet emits a bright white light, and sometimes appears a little after sunset, and again a little before sunrise: but as this planet is so very near the sun, and of itself very small, we seldom see him without a telescope. As seen through a telescope, Mercury exhibits all the phenomena of the moon, which shews that it receives its light from the sun, as does our earth. The periodical revolution, mean distance from the sun, &c. of Mercury, are all given in the foregoing tables. The best observations of this planet are those made when it is seen on the sun's disc or face, called the *transit of Mercury*. The last transit happened in 1822, and the intervals are very remote. The apparent diameter is about eleven seconds; hence the real diameter is 3108 miles, or about one-sixteenth of the magnitude of the earth.

*Venus*, ♀, Fig. 111.—Venus, the next planet above Mercury, is computed to be sixty-eight millions of miles from the sun, and by moving at the rate of seventy-six thousand miles an hour, she completes her annual revolution in 224 days and 16 hours, 49' 11" and a half, and her synodical revolution is about 548

days. Her diameter is seven thousand seven hundred miles, or nearly the size of our earth, and her diurnal rotation on her axis is performed in 23 hours 21 minutes and 7". Venus is often seen by the unassisted eye in broad daylight. The proportion of light and heat received by this planet from the sun is 1·91 times greater than the earth. And it is surrounded with an atmosphere, the refractive powers of which differ very little from ours. Like Mercury, it sometimes passes over the sun's face, and its transit has been applied to one of the most important problems in astronomy, as by it the true distances of the planets from the sun have been determined. These transits take place in the months of June and December. The first will be on the 8th December, 1874. When Venus is to the west of the sun, it rises before the sun, and is called a morning star; this appearance continues about 290 days together; when this planet is to the east of the sun, it sets after the sun, and is called an evening star for about the same period of 290 days. Venus appears the brightest of the planets; it has a considerable atmosphere, and some astronomers assert, that they have discovered mountains on its surface. At times this planet appears gibbous like the moon, fig. 111.

*The Earth*,  $\oplus$ , fig. 112.—The Earth which we inhabit is the planet next in order; hence we say, Mercury and Venus are inferior; but all the planets which are further from the sun than the Earth is, are superior planets. The Earth is 93 millions of miles from the sun; it performs its sidereal revolution in 365d 6h 9' 11" 5; and it passes from the one tropic, to the same again, in only 365d 5h 48' 51" 6. The axis of the Earth is inclined to the plane of the ecliptic in an angle of  $23^{\circ} 27' 57''$ , and the points of intersection are called the equinoctial points; and the ecliptic is the path of the Earth in its annual revolution round the sun.

There are several ways of shewing, that the Earth upon which we live is spherical, like an orange; and this is the form of all the planets. The shadows of bodies in general take the form of their originals. The shadow of the Earth on the moon, that is to say, an eclipse of the moon is, *circular*: the Earth is, therefore, *globular*. Several navigators, by sailing westward, have reached the port they first left. They must, therefore, have sailed round a globular surface. And they have observed, that on leaving land the shores first disappeared, then the hills. On the contrary, approaching land, mountains are first seen, then the shores. These facts also corroborate our illustration of the Earth's sphericity. The Earth is supposed to be surrounded by various lines, that indicate portions of its surface, or enable us to perform the mechanical operations of Geography, Navigation, and Astronomy. The *axis* of the Earth is an imaginary line passing through its centre. Upon this line it is supposed

to turn in its diurnal revolution. The *poles* of the Earth are the extremities of its axis. The lines or circles surrounding the Earth are of two names, *great* and *small*. All great circles divide the Earth into two equal portions; all small circles cut it in unequal parts. The *equator* is a great circle equidistant from both poles. The latitudes of places are reckoned north or south of the equator, as they lie on either side of that line. *Meridians* are great circles of the Earth, crossing the equator at right angles, and terminating in the poles. *Parallels* of latitude are less circles, drawn parallel to the equator. The *longitude* of a place is the distance of the meridian of that place, east or west, from the first meridian. As the Earth revolves round its axis daily from west to east, the heavenly bodies appear to a spectator on the Earth to revolve in the same time from east to west, and the alternate succession of day and night is the effect of the revolution of the Earth towards and from the sun. For all the heavenly bodies appearing to move from east to west, while the Earth revolves from west to east, the sun will appear, in each revolution, to rise above the horizon in the east, and after describing a portion of a circle, to set in the west, and will continue below the horizon, till, by the revolution of the Earth, it again appears in the east: and thus day and night are alternately produced.

The Sun is supposed to be fixed, not in the centre of the Earth's elliptical orbit, but in one of the foci. Let F represent the Sun, (fig. 112) and A B C D the Earth's elliptical orbit. Then A is the perihelion, or lower apsis, being the Earth's nearest

distance from the Sun; C is the aphelion, or higher apsis, being its greatest distance; and the distance between the Sun (in the focus) and the centre S, is called the eccentricity of the Earth's orbit. If from the centre there be erected upon the axis a perpendicular meeting the orbit in L, a point in the centre of the figure B, and the line FL be drawn, it will represent the Earth's mean distance from the Sun, being equal to half the axis AC, consequently FL is 95 millions of miles. The phenomena of the different seasons of the year will appear from the following observations:—Let A B C D represent the Earth's annual orbit, with the Sun in the focus F; *ab*, an imaginary line through the Earth's centre, perpendicular to this plane; the axis N S, of the Earth, forming an angle of  $23^{\circ} 28'$

with this perpendicular: then if the Earth move in A, B, C, D, so that N S may always remain parallel to itself, with the same angle to *ab*, it will denote the seasons; for, a line drawn from the Sun to the Earth, the Sun will be vertical to that part cut by this line. Now, when the Earth is in Libra  $\cap$ , the Sun will appear in Aries  $\gamma$ , and we have *Spring*, the days and nights are equal in both hemispheres, and the season a medium between summer and winter; the line dividing the dark and light hemispheres, passes through the poles N and S, dividing all the parallels of latitude, as P R, equally; hence all the inhabitants of the Earth have their days and nights equal, *viz.* twelve hours each. While the Earth moves from Libra  $\cap$  to Capricorn  $\wp$ , the north pole N will be more enlightened, and

the south pole S more darkened ; hence the days in the northern hemisphere will increase, and in the southern hemisphere decrease, the parallels of latitude being unequally divided. When the Earth has arrived at Capricorn  $\varphi$ , the Sun will appear in Cancer  $\var�$  : this period is a medium between spring and autumn, and is called *Summer* in the northern hemisphere ; in the southern, winter then reigns ; at the north pole, and within the arctic circle, there will be constant day ; at the south pole, and within the antarctic circle, constant night. While the Earth moves from Capricorn  $\varphi$  to Aries  $\gamma$ , the south pole will be more enlightened ; consequently, the days in the southern hemisphere will increase, and decrease in the northern hemisphere. When the Earth has arrived at Aries  $\gamma$ , the Sun will appear in Libra  $\var�$ , and the days and nights be again equal all over the Earth : this period is a medium between summer and winter, and is called *Autumn*. Again, as the Earth moves from Aries  $\gamma$  towards Cancer  $\var�$ , the light will gradually leave the north pole and proceed to the south : when the Earth has arrived at Cancer  $\var�$ , it will be summer in the southern hemisphere, and winter in the northern : the south pole will have continual day, the north pole constant night : this period is a medium between autumn and spring, and is denominated *Winter*. Lastly, while the Earth moves from Cancer  $\var�$  to Capricorn  $\varphi$ , the Sun will appear to move from Capricorn  $\varphi$  to Cancer  $\var�$ , and the days in the northern hemisphere will increase, while those in the southern diminish ; and while the Earth moves from Capricorn  $\varphi$  to Cancer  $\var�$ , the Sun will appear to move from Cancer  $\var�$  to Capricorn  $\varphi$ , the days in the northern hemisphere will decrease, and those in the southern increase. In all situations of the Earth, the equator will be divided equally ; consequently, the days and nights at the equator are always equal. Thus, the different seasons are clearly accounted for, by the inclination of the Earth's axis, the plane of its orbit combined with the parallel motion of that axis.

The axis of the Earth, in its circuit round the sun, being inclined to the plane of its orbit, this inclination occasions the succession of the four seasons. The Earth's axis makes an angle of  $66^{\circ} 32'$  with its orbit, that is, with the ecliptic, and always preserves its parallelism, or is directed towards the same point in the heavens ; hence during one half of the year the north pole is continually illuminated by the sun, and the south pole is all that time in darkness ; and during the other half the year, the south pole is constantly in the light, and the north pole is in darkness ; and other parts in a proportional degree partake of this vicissitude, and create the variety of the seasons. The difference in the degrees of heat, is owing chiefly to the different heights to which the sun rises, and the different lengths of the days. When the sun rises highest, in summer, its rays fall less obliquely, and consequently more of them fall on any given portion of the Earth's surface than in winter, when the rays fall obliquely ; and when the days are long, and the nights short, the earth and air are more heated in the day than they are cooled in the night, and the reverse when the days are short and the nights long. The lengthening and shortening of the days, and the different seasons, are produced by the motion of the Earth, N S, fig. 112, in its orbit round the sun, F. The axis of the Earth N S inclines to the plane of the orbit, and is parallel to itself in all parts of the orbit. In June the north pole N inclines to the sun, and it is summer in the northern parts of the earth ; in December the north pole declines from the sun, and it is winter in the northern and summer in the southern hemisphere.

There are several ways of demonstrating that the planets move round the sun ; thus, Mercury and Venus always appear in the neighbourhood of the sun, and if the sun revolved round the Earth as a centre, so must these planets ; but if they did, then the motion of each would always appear to us nearly equable, and in the same direction ; whereas now they are sometimes stationary, or have no proper motion ; sometimes they move eastward in reference to the fixed stars, and their motion is then called direct, progressive, or *in consequentia* ; sometimes they move westward, and have a retrograde motion, when they are said to move *in antecedentia* ; appearances which are necessary, when we admit the sun to be the centre of their orbits, and of the Earth's, but wholly irreconcilable with any other hypothesis.

Moreover, when Mercury and Venus appear in conjunction with the sun, they are sometimes hid behind the body of the sun, and sometimes pass between it and the Earth, appearing like a dark spot on the sun's disc or face ; but if they have latitude, when in their superior conjunction, that is, when beyond the sun, they shine with a face perfectly circular, like a full moon. But the face disappears in their inferior conjunction, that is, when between us and the sun, as the moon does at her change ; whence it is evident, that their orbits are between the sun and the orbit of the Earth. Mars sometimes appears in opposition to the sun, which proves that its orbit includes that of the Earth ; and that it includes the sun is plain, otherwise Mars would, in its conjunction with the sun, disappear, like Mercury and Venus, which never happens : the same may be observed of Jupiter, Saturn, and Herschel. The motions of the Earth in its orbit are proved, by the effect of its motion on the apparent motions of the several planetary bodies. These, as the Earth happens to be situated, become stationary, retrograde, or direct, and the variations are exactly measured by motions referred to the Earth, like the motions of objects ashore, when we are moving in a boat.

As the Earth revolves round the sun in 365 days, 6 hours, 56 minutes, 4 seconds, the sun appears to revolve round the Earth in the same time, but in the contrary direction. It is manifest, that the circle in which the sun appears to move, is the same in which the Earth would appear to move to a spectator in the sun. Hence the apparent place of the sun being found, the true place of the Earth in its orbit is known to be  $180^{\circ}$  distant. The orbit in which the Earth revolves round the sun, fig. 112, is an ellipse, having the sun in one of its foci. For the computations of the sun's place, upon this supposition, allowing for the disturbing forces of the planets, are found to agree with observations. The circle which the sun appears to describe annually among the more distant fixed stars, is called the *Ecliptic* ; and a portion of the heavens, about 16 degrees in breadth, through the middle of which the ecliptic is traced, is called the *Zodiac*, in which the orbits of all the planets are described by their respective revolutions. The stars round the Zodiac are classed in 12 *signs* : Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricorn, Aquarius, Pisces. Figures, representing these signs, are drawn in Dr. Jamieson's *Celestial Atlas*, and upon the *Celestial Globe*, in that portion of its spherical surface which corresponds to the portion of the concave sphere of the heavens in which the stars belonging to each sign are respectively found.

#### Spring Signs.

$\gamma$  Aries, the Ram, 21st March.  
 $\tau$  Taurus, the Bull, 19th April.  
 $\var�$  Gemini, the Twins, 20th May.

These are called Northern Signs, being north of the equinoctial.

#### Autumnal Signs.

$\var�$  Libra, the Balance, 23d September.  
 $\var�$  Scorpio, the Scorpion, 23d October.  
 $\dagger$  Sagittarius, the Archer, 22d November.

#### Summer Signs.

$\var�$  Cancer, the Crab, 21st June.  
 $\var�$  Leo, the Lion, 22d July.  
 $\var�$  Virgo, the Virgin, 22d Aug.

#### Winter Signs.

$\var�$  Capricornus, the Goat, 21st December.  
 $\var�$  Aquarius, the Water-bearer, 20th January.  
 $\times$  Pisces, the Fishes, 19th February.

These are called southern signs. The spring and autumnal signs are called ascending signs ; because when the sun is in any of these, his declination is increasing. The summer and winter signs are called descending signs ; because when the sun is in any of these, his declination is decreasing.

The axis of the Earth in every part of the Earth's revolution about the sun, makes, with the plane of its orbit, that is, of the ecliptic, an angle of  $66\frac{1}{2}$  degrees, consequently the planes of the equator and ecliptic make with each other an angle of  $23\frac{1}{2}$  degrees nearly, being the complement of  $90$  degrees. The obliquity of the ecliptic is not permanent, but is continually diminishing by the ecliptic approaching nearer to a parallelism with the equator, at the rate of about half a second in a year, or from  $50''$  to  $55''$  in 100 years. The inclination at this time is  $23^{\circ} 27' 46''$  nearly. The diminution of the obliquity of the ecliptic to the equator, is owing to the action of the planets upon the earth, especially the planets Venus and Jupiter. The whole diminution, it is said, can never exceed one degree, when it will again increase. The diminution of the obliquity of

the ecliptic is a consequence of the approach of the Earth's axis towards a perpendicular direction to the plane of the ecliptic; but the Earth's axis has, besides the progressive motion, a tremulous one, by which its inclination to the plane of the ecliptic varies backwards and forwards some seconds: the period of these variations is nine years. The tremulous motion is termed the nutation of the Earth's axis. Both these motions of the terrestrial axis are occasioned by the action of the sun, moon, and planets on the earth.

There are several other astronomical phenomena, that belong to these scientific views of the Earth; but we will give them in their proper places, rather than encumber this article with what is more detached.

*The Moon*, the Earth's satellite, has motions eccentric and irregular. She performs her sidereal revolution in  $27^d 7^h 43' 11''.5$  But this period is variable, and on comparison of the modern observations with the ancients, proves incontestably an acceleration in her mean motion. Her mean tropical revolution is  $27^d 7^h 43' 4''.7$ ; and her mean synodical revolution is  $49^d 12^h 42' 2''.8$ . Her mean distance from the earth is 29'982175 times the diameter of the terrestrial equator; or above 237,000 miles. Her orbit is inclined to the plane of the ecliptic in an angle of  $5^\circ 9'$ ; but this inclination is variable. The greatest inequality, which sometimes extends to  $8' 47''.1$ , is proportional to the co-sine of the angle on which the inequality of the nodes depends. Her orbit, at the commencement of the present century, crossed the ecliptic in  $0s 15^\circ 55' 26''.3$ ; but the place of her nodes is variable. They have a retrograde motion, and make a sidereal revolution in about 18'6 Julian years. A synodical revolution of the nodes is performed in  $346^d 14^h 52' 43''.6$ . The motion of the nodes is subject also to a secular inequality, dependent on the acceleration of the Moon's mean motion. The rotation of the Moon on her axis is equal and uniform; and it is performed in the same time as the tropical revolution in her orbit, whence she always presents nearly the same face to the earth. But, as the motion of the Moon in her orbit is periodically variable, we sometimes see more of her eastern edge, and sometimes more of her western edge. This appearance is called the libration of the Moon in longitude. The axis of the Moon is inclined to the plane of the ecliptic in an angle of  $88^\circ 29' 49''$ . In consequence of this position of the Moon, her poles alternately become visible to, and obscured from us: and this phenomenon is called her libration in latitude. There is also another optical deception, arising from the Moon being seen from the surface of the earth, instead of the centre. This appearance is called her diurnal libration. The figure of the Moon A, B, C, &c. (fig. 113,) is that of an oblate spheroid like the earth T. Her mean diameter is in the proportion to that of the earth, as 5823 to 21332; or, as 1 to 3'665. Whence her mean diameter will be about 2160 miles. But the apparent diameter of the Moon varies according to her distance from the earth. When nearest to us, it is  $33' 31''.1$ ; and at her greatest distance it is  $29' 21''.5$ . Hence her mean apparent diameter is  $31' 26''.5$ . The different phases of the Moon constitute some of the most striking phenomena of the

separates from the sun this crescent increases, *c, d*, till in opposition, *e*, when the moon is completely illuminated. This circle changes reversely into a crescent, *f, g, h*, till the Moon has plunged into the sun's rays in the morning at sun-rise. And the crescent being always directed to the sun, indicates that the Moon is herself a dark opaque body, borrowing her light from the sun. These different phases, A, B, C, D, &c. of the Moon are renewed after every conjunction; and the points of the lunar orbit, in which the Moon is either in conjunction or opposition to the sun, are called the *syzygies*. In the first point, the Moon is new, in the second full; in her first quarter the Moon is  $90^\circ$  from the first point; in her third quarter  $270^\circ$  from the same point.

*Mars*,  $\gamma$ , fig. 114.—Mars first above the earth's orbit is easily known by his red and fiery appearance. He performs his sidereal revolution in  $686^d 23^h 30' 39''$ , or in 1'881 Julian year; and his mean synodical revolution is about 780 days, or in about 2'135 years. His mean distance from the sun is above 142 millions of miles. The rotation on his axis is performed in  $1^d 0^h 39' 21''.3$ ; and his mean diameter is 4398 miles, or rather

more than one half the size of our earth. This planet has a very dense but moderate atmosphere, and he is not attended by any satellite. And the proportion of light and heat received by him from

the sun is .43, that received by the earth being considered as unity. Mars changes his phases in the same manner as the moon does, from her first to her third quarter, according to his various positions with respect to the earth and sun.

*Vesta*  $\diamond$ .—This planet was discovered by Dr. Olbers, of Bremen, on the 29th of March, 1807: its distance from the sun is 225,435,000 miles, and the length of its year, 3 years 240 days 5 hours. Vesta appears like a star of the fifth magnitude.

*Juno*  $\ddagger$ .—Juno was discovered by Mr. Harding, of Lilienthal, in the duchy of Bremen, on the first of September, 1804. It appears like a star of the eighth magnitude: its distance from the sun is 253,380,485 miles, and its periodical revolution is performed in 4 years and 131 days.

*Ceres*  $\rho$ .—Ceres was discovered by M. Piazzi, astronomer royal, at Palermo, in the island of Sicily, on the 1st of January, 1801. The length of its year is 4 years 221 days 13 hours; its distance from the sun is 262,903,570 miles, and its diameter, according to Dr. Herschel, is about 162 miles. Ceres appears like a star of the eighth magnitude.

*Pallas*  $\phi$ , was discovered by Olbers on the 28th of March, 1802. Its distance from the sun is 253,000,000 miles. Its annual revolution is completed in about 4 years 7 months and 10 days. Like the two former newly discovered planets, its diameter and diurnal rotation are as yet unknown.

*Jupiter*,  $\mathcal{U}$ , fig. 116, is about four hundred and eighty-five millions of miles from the sun. It completes its annual revolution in about 12 years, moving at the rate of 29,000 miles an hour. Its diameter is 91,500 miles, yet by an exceedingly rapid motion upon its axis, the diurnal rotation is performed in nine

hours and 55 minutes! Notwithstanding the great distance of this fine planet from the sun and the earth, it appears, to the naked eye, almost as large as Venus, though with a less brilliant light. When Jupiter rises as the sun sets, and sets as the sun rises, it comes to the meridian at midnight, and appears larger and more luminous than at other times. It is a morning

heavens. When she emerges from the sun's rays, S, in the evening, she appears as a small crescent, *b*, just visible; but as she

star when its longitude is less than that of the sun, and an evening star when the longitude is greater than that of the sun. Jupiter is surrounded by faint substances, called zones or belts, which, from their frequent change in number and situation, are generally supposed to consist of clouds. One or more dark spots frequently appear between the belts; and when a belt disappears, the contiguous spots disappear likewise. The time of the rotation of the different spots is variable, being less by six minutes near the equator than near the poles.

**Satellites of Jupiter.**—By the aid of the telescope we may discover four satellites revolving round Jupiter. The sidereal revolutions of these bodies are given in the following table: together with their mean distances from Jupiter, the semidiameter of that planet's equator being considered as unity; and likewise their masses, compared with Jupiter, considered also as unity.

TABLE.

| Satellite. | Sidereal Revolution. |                 | Mean Distance. | Mass.       |
|------------|----------------------|-----------------|----------------|-------------|
| I.         | 1d 18h 27' 33",5     | 1d 769137788148 | 5·812964       | ·0000173281 |
| II.        | 3 13 13 42 ,0        | 3 551181017849  | 9·248679       | ·0000232355 |
| III.       | 7 3 42 33 ,4         | 7 154552783970  | 14·752401      | ·0000884972 |
| IV.        | 16 16 31 49 ,7       | 16 688769707084 | 25·946860      | ·0000426591 |

The satellites of Jupiter are liable to be eclipsed by passing through his shadow; and on the other hand, they are frequently seen to pass over his disk, and eclipse a portion of his surface. This happens to the first and second satellite at every revolution; the third very rarely escapes in each revolution; but the fourth (on account of its great distance and inclination) is seldom obscured. These eclipses are of great utility, in enabling us to determine the longitude of places, by their observation; and they likewise exhibit some curious phenomena with respect to light. From the singular analogy above alluded to, it follows, that, (for a great number of years at least,) the first three satellites cannot be eclipsed at the same time: for in the simultaneous eclipses of the second and third, the first will always be in conjunction with Jupiter, and *vice versa*.

**Saturn, ♄, fig. 117.**—Saturn is about eight hundred and ninety millions of miles from the sun. It moves at the rate of 22,000 miles an hour, and performs its annual revolution in a little less than 29½ years. His mean distance from the sun is above 890 millions of miles. The rotation on its axis is performed in 10h 16' 19",2; and the axis is inclined in an angle of 58° 41' to the plane of the ecliptic. His mean diameter is 76068 miles; consequently he is nearly ten times as large as our earth. The axis of his poles is to his equatorial diameter as 11 to 12. The proportion of light and heat received from the sun is ·0011; that received by the earth being considered as unity. Saturn is sometimes marked by zones or belts, which are probably obscurations in his atmosphere; and he is

accompanied by seven satellites. The most singular phenomenon, however, attending this planet, is the double ring with which he is surrounded. This ring, which is very thin and broad, is inclined to the plane of the ecliptic in an angle of 31° 19' 12",0; and revolves from west to east, in a period of 10h 29' 16",8, about an axis perpendicular to its plane, and passing through the centre of the planet. The breadth of the

ring is nearly equal to its distance from the surface of Saturn; that is, about one-third of the diameter of the planet. The surface of the ring is separated in the middle by a black concentric band, which divides it into two distinct rings. The edge of this ring, being very thin, sometimes disappears; and, as this edge will present itself to the sun twice in each revolution of the planet, it is obvious that the disappearance of the ring will occur about once in 15 years, but under circumstances oftentimes very different. The intersection of the ring and the ecliptic is in 5s 20° and 11s 20°; consequently, when Saturn is in either of those signs, his ring will be invisible to us. On the contrary, when he is in 2s 20° or 8s 20°, we may see it to most advantage. This was the case towards the end of the year 1811.

**Satellites of Saturn.**—Seven satellites may be seen, by means of the telescope, to revolve about Saturn; the elements of which are but little known, on account of their great distance. The following table will shew the duration of their sidereal revolutions, and their mean distances in semidiameters of Saturn.

| Satellite. | Sidereal Revolution. |          | Mean Distance. |
|------------|----------------------|----------|----------------|
| I.         | 0d 22h 37' 30",1     | 0d 94271 | 3·080          |
| II.        | 1 8 53 8 ,7          | 1 37024  | 3·952          |
| III.       | 1 21 18 25 ,9        | 1 88780  | 4·893          |
| IV.        | 2 17 44 51 ,1        | 2 73948  | 6·268          |
| V.         | 4 12 25 11 ,1        | 4 51749  | 8·754          |
| VI.        | 15 22 41 13 ,9       | 15 94530 | 20·295         |
| VII.       | 79 7 54 37 ,4        | 79 32960 | 59·154         |

The orbit of the first six satellites appear to be in the plane of Saturn's ring; whilst the seventh varies from it very sensibly.

**Uranus, or Herschel, ♅,** called also *Georgium Sidus*, was discovered by Dr. Herschel on the 13th of March, 1781. Its distance from the sun is about one thousand eight hundred millions of miles, and its diameter 35,000. Its annual revolution is completed in about eighty-four years, and its rotary motion in about the same time as Saturn. The appearance of Uranus is that of a star of the sixth magnitude, and therefore it can scarcely be seen without a telescope. The intensity of light or heat, on this distant planet, is to that on the earth as 276 is to 100,000. And the sun's diameter, as seen from Uranus, is about the magnitude of Jupiter's when in opposition.

**Satellites of Uranus.**—Six satellites revolve round Uranus; which, together with their primary, can be discovered only by the telescope. The following table will shew their sidereal revolutions, and mean distances in semidiameters of the primary.

| Satellite. | Sidereal Revolution. |          | Mean Distance. |
|------------|----------------------|----------|----------------|
| I.         | 5d 24h 25' 20",6     | 5d 8926  | 13·120         |
| II.        | 8 16 57 47 ,5        | 8 7068   | 17·022         |
| III.       | 10 23 3 59 ,0        | 10 9611  | 19·845         |
| IV.        | 13 10 56 29 ,8       | 13 4559  | 22·752         |
| V.         | 38 1 48 0 ,0         | 38 0750  | 45·507         |
| VI.        | 107 16 39 56 ,2      | 407 6944 | 91·008         |

All these satellites move in a plane, which is nearly perpendicular to the plane of the planet's orbit, and contrary to the order of the signs.

**Of Comets.**—Comets are opaque and solid bodies. A Comet, at a given distance from the earth, shines much brighter when it is on the same side of the earth with the sun, than when it is on the contrary side; from whence it appears, that it owes its brightness to the sun. Of all the comets, the periods of only three are known with any degree of certainty. The first of these Comets appeared in the years 1531, 1607, and 1682; and is expected to appear every 75th year. The second of them appeared in 1532 and 1661, and was expected to return in 1789, and every 129th year afterwards. The third having last appeared in 1680, and its period being no less than 575 years,

cannot return until the year 2225. This Comet, at its greatest distance, is about eleven thousand two hundred millions of miles from the sun; and at its least distance from the sun's centre, which is 49,000 miles, is within less than a third part of the sun's semidiameter from his surface. In that part of its orbit which is nearest the sun, it moves at the rate of 880,000 miles in an hour. The Chinese astronomers record the appearance of about 300 Comets. The tail of the Comet of 1680 was at least 100 millions of miles long; and that of 1812 was 30 millions of miles. The Comets trace, around the sun, very elongated ellipses, which degenerate into parabola. Hence their appearance in our heavens is only momentary, because we can see them in only so small a portion of the curve they describe, though for some it extends to the confines of the solar system. This motion is without fixed direction; the Comets re-act every way, and frequent perturbations make their course devious. Such effect did the re-action of Saturn and Jupiter produce on the comet of 1759. By the action of Jupiter, that of 1770 deviated so much when towards its perihelion, that its orbit became elliptic. On its return, the same effect in a contrary direction caused it to resume its parabolic course. The cause of this luminosity, called the *tail* of a Comet, has been thus described:—

“Suppose a globe of water, with an opaque ball in its centre—in other words, the pellucid atmosphere of a comet and its nucleus—suppose them placed in the sunshine (the situation of a Comet at all times,) is it not then evident that the globe of water, with its opaque ball, would, by the refraction and reflection of rays of light, exhibit all the phenomena of a Comet's tail, under all the circumstances and variations of that tail? By the ordinary laws of refraction, the tail would be lengthened as it approached the sun, and would shorten as it receded, which we know accords with the phenomena.

“The tail of a Comet is thence considered a grand optical exhibition of the phenomena of light. As the solar rays pass in their ordinary course through the medium of space, they exhibit no peculiar appearances; but when they impinge on the atmosphere of a planetary body, they undergo refractions and reflections; then they exhibit their general, visual phenomena, whether it be as condensed in the shape of a Comet's tail, or in giving luminosity to the figure of a planet. As the spherical refracting medium approaches the source of light, the foci of convergency of course are extended, and the quantity of light is increased; and then is the Comet's tail of the largest dimensions, and the most luminous. As it recedes from the fountain of light, the foci draw nearer to the Comet, and the tail shortens; at length the Comet recedes so far from the sun, that the quantity of light ceases to produce the same visual effect, while the increased distance from the earth combines also to render it altogether invisible.

“Telescopes destroy the tail, because they magnify the space without increasing the light, an effect which is universal when they are applied to luminous objects, but more sensible in regard to a Comet's tail than to any other object of telescopic observation; serving, therefore, to prove that it is light itself, rather than any crude vapour on which light is impinging. The stars are seen through it, because they shine by their inherent light, and there is no substance or opacity intercepting their rays.

“Supposing that fluids and solids compose nearly equal parts of Comets, it will not be difficult to explain their varied aspect. The sun's expansive action being null in its aphelion, it exhibits properties analogous to opaque bodies, but less marked, the fluids being adequate to produce a proper light. In this state, the Comet has a solid and opaque nucleus; proportionally greater, from the aqueous vapours condensed from its atmospheres; which last is of a moderate extent.

“How pleasing is the idea of contemplating these travelling worlds, peopled with observers, employed in contemplating the universe at large, as we are busied in that of an insignificant atom of it; passing from one sun to another, observing the orbits of the celestial spheres; viewing their particular and general revolutions; over their heads thousands of years rolling, merely as thousands of days over ours!”

For the laws by which the planets are kept in their respective positions, or whirled with unerring precision round the

sun, and amongst one another, see the articles *ATTRACTION* and *LAWS OF PLANETARY MOTION*.

*The Fixed Stars.*—Besides the sun, planets, and comets which we have noticed, as belonging to our system, there are other phenomena that we may observe, as the Fixed Stars, distinguished from the planets, by being less bright, less luminous, and exhibiting continually an appearance, which we call the *twinkling of the stars*. The Fixed Stars are so named from their never changing their situation with regard to each other, as the planets change their places. They are, thence, considered suns of other systems or worlds. How magnificent then is this universe!

1. The Fixed Stars are luminous bodies. Because they appear as points of small magnitude when viewed through a telescope, they must be at such immense distances as to be invisible to the naked eye, if they borrowed their light; as is the case with respect to the satellites of Jupiter and Saturn, although they appear of very distinguishable magnitude through a telescope. Besides, from the weakness of reflected light, there can be no doubt but that the Fixed Stars shine with their own light. They are easily known from the planets by their twinkling.

2. The number of Stars, visible at any one time to the naked eye, is about 1000; but Dr. Herschel, by his skilful improvements of the reflecting telescope, has discovered that the whole number is great beyond all conception. The comparative brightness of the Stars is, Sirius 100, Canopus '98, Centauri '96, Achernar '94.

3. The magnitudes of the Fixed Stars appear to be different from one another, which difference may arise either from a diversity in the real magnitudes, or distances; or from both these causes acting conjointly. The difference in the apparent magnitude of the Stars is such as to admit of their being divided into six classes, the largest being called Stars of the first magnitude, and the least which are visible to the naked eye, Stars of the sixth magnitude. Stars only visible by the help of glasses are called telescopic Stars. Bode's catalogue contains 17,000 Stars. Dr. Halley very justly remarks, that the Stars must be infinite in number, to maintain their equilibrium in space. And Dr. Herschel thinks he has seen Stars 42,000 times as far off as Sirius. In one instance, a cluster of 5000 stars, in a mass, were barely visible in the 40-foot telescope, and consequently must have been 11 trillions of miles off!

4. It must not be inferred, that all the Stars of each class appear exactly of the same magnitude, there being great latitude given in this respect; even those of the first magnitude appear almost all different in lustre and size. There are also other Stars of intermediate magnitudes, which, as astronomers cannot refer to any one class, they, therefore, place them between two; or that, in place of six magnitudes, there are probably as many different magnitudes as there are Stars.

5. To the naked eye, the Stars appear of some sensible magnitude, owing to the glare of light arising from numberless reflections of rays coming to the eye; this leads us to imagine, that the Stars are much larger than they would appear, if we saw them only by the few rays which come directly from them, and entered the eye without being intermixed with others. Examine a Fixed Star of the first magnitude, through a long and narrow tube, which, though it takes in as much of the sky as would hold a thousand such stars, scarcely renders that one visible. Even our best telescopes do not enlarge these gems; and there seems but little reason to expect, that the real magnitudes of the Fixed Stars will ever be discovered with certainty; we must, therefore, be contented with an approximation, deduced from their parallax, and the quantity of light they afford us compared with the sun. To this purpose, Dr. Herschel, with a magnifying power of 6450, and by means of his new micrometer, found the apparent diameter of  $\alpha$  Lyrae to be  $0^{\circ}.335$ , or the third of a second.

The ingenious observations of Kepler upon the magnitudes and distances of the Fixed Stars, have been followed by Dr. Halley. He observes, that there can be only 13 points upon the surface of a sphere as far distant from each other as from the centre; and supposing the nearest Fixed Stars to be as far from each other as from the sun, he concludes, that there can be only 13 Stars of the first magnitude. Hence, at twice that

distance from the sun, there may be placed four times as many, or 52; at three times that distance, nine times as many, or 117; and so on. These numbers will give pretty nearly the number of stars of the first, second, third, &c. magnitudes. Dr. Halley farther remarks, that if the number of Stars be finite, and occupy only a part of space, the outward stars would be continually attracted to those within, and in time would unite into one. But if the number be infinite, and they occupy an infinite space, all the parts would be nearly in equilibrio, and consequently, each Fixed Star being drawn in opposite directions, would keep its place, or move on till it had found an equilibrium.

A Constellation is a number of Fixed Stars, lying in the neighbourhood of each other, which astronomers, for the sake of remembering with more ease, suppose to be circumscribed by the outline of some animal or other figure. See CONSTELLATION.

An Eclipse of the Sun is caused by the moon passing between the sun and the earth; and an Eclipse of the Moon is the effect of the earth passing between the sun and moon. See ECLIPSE.

ASTROSCOPE, an astronomical instrument, composed of two cones, on whose surfaces are exhibited the stars and constellations, by means of which they are both easily found in the heavens. This instrument was the invention of Schukhard, professor of mathematics at Tübingen, who published a treatise expressly on it in 1698.

ASTROSCOPIA, is the art of observing and examining the stars with the telescope, in order to discover their nature and properties.

ASTROTHERESIA, an ancient term, nearly synonymous with constellation.

ASTRUM, or ASTRON, a constellation or assemblage of stars, the same as Aster denotes a single star.

ASYLUM, a sanctuary, or place of refuge, where criminals shelter themselves from the hands of justice. The *asyla* of altars, temples, tombs, statues, &c. is very ancient. The Jews had six cities of refuge, the temple and the altar of burnt-offering. The temple of Diana, at Ephesus, was a refuge for debtors; hence, when the apostle of our Lord preached salvation to the worst of mankind, it included also the hapless debtor, who would thus be restored to the favour of the Deity; an idea in no ways compatible with the notions of the heathen creditor.—The emperors Honorius and Theodosius granting particular immunities to churches, the bishops and monks laid hold of a certain tract or territory, without which they fixed the bounds of the secular jurisdiction; and so well did they manage their privileges, that convents, in a little time, became next akin to fortresses, where the most notorious villains were in safety, and braved the power of the magistrate.

ASYMETRY, without measure, a want of proportion between the parts of a thing, as between the side and diagonal of a square, which are to each other as 1 :  $\sqrt{2}$ .

ASYMPTOTE, incoincident, is properly a right line, which approaches continually nearer to some curve, whose asymptote it is said to be, in such sort, that when they are both indefinitely produced, they are nearer together than by any assignable finite distance; or it may otherwise be considered as a tangent to the curve, when infinitely produced, or at an infinite distance. Two curves are also said to be asymptotical, when they thus continually approach indefinitely to a coincidence: thus two parabolas placed with their axis in the same right line, are asymptotes to each other. Of lines of the second kind, or curves of the first kind, that is, the conic sections, only the hyperbola has asymptotes, which are two in number. All curves of the second kind have at least one asymptote, but they may have three; and all curves of the third kind may have four asymptotes, and so on. The conchoid, cissoid, and logarithmic curve, though not geometrical curves, have each one asymptote; and the branch or leg of the curve that has an asymptote, is said to be of the hyperbolic kind. The nature of an asymptote is very difficult to be conceived by persons who are not acquainted with the higher geometry: they cannot comprehend how two lines should always continually approach each other, without the possibility of touching or coinciding; this mystery, however, may be elucidated, and the nature of these lines readily comprehended, by considering the generation of the conchoid of Nicomedes, which is as follows. Let

FK (fig. 118.) be any line indefinite towards K, and from the point P let there be drawn the lines PA, PB, PC, PD, &c. making the several parts FA, GB, HC, ID, KE, &c. all equal to each other: the curve ABCDE, &c. passing through all the extremities A, B, C, D, &c. is called the conchoid of Nicomedes; and the line FK produced, is the asymptote of the curve; and which, it is obvious from the

construction, can never coincide or touch the curve itself, although the latter continually approaches towards the former.

ATAR OF ROSES, a precious essence, which is easily obtained, provided the material from which it is extracted is supplied in quantities sufficient for the purpose, but unfortunately one hundred weight of roses generally yields but from two to three ounces of Atar. The roses, with their calyxes, are to be immersed in double their weight of water, and distilled by a very gentle heat, from which will be obtained a very strongly scented rose wine. This must be cooled as quickly as possible by the night air, and the globular particles found upon its surface, carefully gathered the next morning, which are more or less abundant, according to the perfection of the roses. A peculiarly fragrant grass is employed in Persia along with the roses, besides other odorous vegetable substances which that rich climate produces; but although the quantity of essence is thereby increased, its quality is deteriorated. Even after the Atar has been gathered, the rose-water that remains is powerfully scented. It is not necessary to distil the roses immediately after they have been gathered, as that may be inconvenient, particularly on account of the heat of the weather when the flower is produced. Rose leaves, as well as other flowers capable of affording fragrant essential oils, may be preserved for a long period, as in a pot-pourie, without losing any of their odour, or by being well rubbed, and mixed into a paste with common salt. The quantity of oil and water is said to be greatly increased by the salting process, which is indeed probable. The proportion of salt is one pound to three pounds of leaves. The flowers being bruised by the friction of the grains of salt, form a paste, which should be preserved in an earthen jar or barrel; continuing the process uniformly until the barrel or jar is filled, which may be kept in a cool place for several years, without impairing its flavour or strength. This aromatic paste may be distilled at any season of the year, mixing it with about twice its weight of water before you put it into the still. Indeed, in many gardens in Britain a sufficient quantity of rose leaves might be gathered in a couple of years, to verify this recipe for the extraction of Atar of roses. The generality of perfumes are made up of musk, civet, ambergris, cedar, roses, orange flowers, jonquils, jessamines, tuberoses, and other odoriferous flowers and plants; and their use among the Hebrews, and most of the Oriental nations, was common, before they were known to the Greeks and Romans. But as the nervous system is very much affected by the use of these volatile drugs, medical men generally strongly condemn the practice, still so much in fashion, of scenting the clothes, hands, face, &c. with musk, atar of roses, &c.

ATARGATIS, a goddess of the Syrians, represented with the head and breasts of a woman, and the tail of a fish. Both the Syrians and Egyptians abstained from eating fish, which they seem to have held in singular dread and abhorrence, and when the Egyptians had to represent any thing as odious, or to express hatred by hieroglyphics, they painted a fish. A deity of the name of Dagon was worshipped under the form of a monster, which had the head and arms of a man, and the tail of a fish. This appears to have been the symbol of the sun in Pisces, and was considered as the principle of fecundity; hence Dagon seems to have been employed to signify the "corn and fruits of the earth." No sign appears to have been considered of more malignant influence than Pisces. The astrological calendar describes the emblems accompanying

this constellation as chiefly indicative of violence and death ; yet the month of February, when the sun was in Pisces, was called Adar ; perhaps in honour of the moon, which was adored by the title Adra Daga, or the, "glorious fish."

**ATCIEVEMENT**, or **ACHIEVEMENT**, in Heraldry, the arms of a person or family, marshalled in order ; with quarterings by alliance, mottos, scrolls, crest, mantle, helmet, &c.

**ATHAMANTA**, spignel.

**ATHANASIA**, goldilocks.

**ATHANASIAN CREED**, the exposition of faith composed by Hilary, bishop of Arles, about the year 430, and which was received at Rome about the year 1014, as a summary of the orthodox faith, and a condemnation of all heresies.

**ATHWART**, in Navigation, across the line of the course ; *athwart the forefoot*, the direction of a cannon ball from one ship across another, to intercept the latter, and oblige her to shorten sail, and heave to, that the former may come near enough and examine her. *Athwart hause*, the situation of a ship when she is driven by wind or tide, or any other accident, across the fore part of another ship.

**ATLAS**, in matters of literature, a book of maps, either celestial, as Dr. Jamieson's atlas ; or terrestrial, as Arrow-smith's atlas.

**ATRIPLEX**, orach, or arach.

**ATROPA**, deadly nightshade, whose horrid black berries and root are the rankest poisons.

**ATTACHMENT**, in Law, the apprehending of a person by virtue of a writ. An attachment is issued out of a higher court than a writ, and may lie against the body and goods.

**ATTAINDER**, in Law, the immediate inseparable consequence of sentence of death being pronounced upon a criminal : or when a person flees from justice, which is tacitly confessing his guilt, the judgment of outlawry is the attainder, for the person is stained, *attinctus*, or blackened, by his own act.

**ATTITUDE**, in Painting and Sculpture, the gesture of a figure or statue ; or such a disposition of their parts as serves to express the action and sentiments of the person represented.

**ATTORNEY AT LAW**, one put in the place of another person, to manage his matters in law. The attorneys are a regular corps, admitted to the execution of their duties by the superior courts of Westminster Hall, and are in all points officers of the respective courts into which they are admitted. The Attorney-general, a great officer appointed by the king's letters patent, prosecutes for the crown in matters criminal. His proper place in court is under the judges, on the left of their clerk : usually, however, he sits within the bar in front of the court.

**ATTRACTION**, the tendency which all bodies have to approach each other, is distinguished into the attraction of cohesion, and the attraction of gravitation. The attraction of cohesion takes place between bodies, only when they are at very small distances from each other. By this attraction, possessed by the minute parts of matter, bodies preserve their form, and are prevented from falling to pieces. To prove the attraction of cohesion, take two pieces of lead with flat surfaces ; scrape them clean with a knife, squeeze them together, and they will adhere so firmly as to be separated with difficulty. And if you wet two bits of glass with water, they also will adhere firmly. Two globules of quicksilver placed near each other, will run together, and become one drop or ball.

*A Table of cohesive Powers of different Solids.*—To estimate the absolute cohesion of solid bodies, Professor Musschenbroeck, applied weights to separate them according to their length. The pieces of wood he used were parallelopipedons, whose side was  $\frac{7}{100}$ ths of an inch. The metal wires used were  $\frac{1}{16}$ th of a Rhinland inch in diameter. They were drawn asunder by the following weights :

|             | lbs. |              | lbs. |
|-------------|------|--------------|------|
| Fir .....   | 100  | Copper ..... | 299½ |
| Elm .....   | 950  | Brass .....  | 360  |
| Alder ..... | 1000 | Gold .....   | 500  |
| Oak .....   | 1150 | Iron .....   | 450  |
| Beech ..... | 1250 | Silver ..... | 370  |
| Ash .....   | 1250 | Tin .....    | 49½  |
| Lead .....  | 29½  |              |      |

**Capillary Attraction**—is accounted a species of cohesion. It is called capillary, from the tubes which draw the water above its level being small as hairs. And the suspension of fluids in capillary tubes is owing to the attraction of the ring contiguous to the upper surface of the fluid. The height to which the fluid rises is inversely as the diameter of the bore. *Experiments*: Take a small glass tube open at both ends, dip it in water, and the water will rise in the tube higher than its level in the basin : the water will rise the higher, the smaller the bore of the tube is. Take two pieces of glass, five or six inches square, join any two of their sides, separate the opposite sides with a small piece of wood, so that the surface may form a small opening, and immerse them about an inch deep in a basin of coloured water : then the water will rise between the glasses, and form a very beautiful curve. Upon the same principle it is that a piece of sugar, or a sponge, draws up water or any other fluid. All vegetables are but bundles of capillary tubes ; and whether we consider earth, water, salt, and oil, as the food of plants, that food must be formed by water into an emulsion, capable of being acted upon by capillary attraction ; unless we suppose the juice, or food, to rise in those tubes by some law of hydraulics. As all the roots are but assemblages of these tubes, there can be little doubt but their attraction supplies the plant or tree with its first food ; though other causes, no doubt, assist in carrying it to the tops of the tallest trees, such as dilatation and contraction, by the successive heat and cold of day and night ; the muscular action of vascular rings round the tubes, irritated to contraction by the stimulant sap, &c. The interior bark conducts the nourishment supplied by the earth. Leaves on one side draw nutrition also from the air, and perspire on the other ; light probably does the rest. It is probably owing to the various degrees of cohesion, that some bodies are hard and others soft ; that some are in a solid, others in a fluid state. For when attraction prevails in bodies, they become solid ; when fire prevails, they become gas ; hence fluidity seems a medium between both. As it is by the attraction of cohesion that the parts of bodies are kept together, this attraction is overcome when a body is broken. Hence the reason of soldering metals, gluing wood, &c. Hence, also, when the particles, or molecule, of which a body is composed, so adhere the one to the other, that they cannot be separated without effort, we say of such a body that it is solid ;—such are metals, stone, wood, &c. Hence, also, such substances as are composed of particles adhering very slightly, and which, yielding to any small effort, are easily moved among each other, we term fluids, such as water, beer, air, &c. These properties may result from the different figures of the particles, and the greater or less degree of attraction thereupon. Elasticity may arise from the particles of a body, when distended, not being amply drawn into each other's attraction ; as soon, therefore, as the force which acts upon it ceases, they restore themselves to their former position. Density, strictly speaking, denotes the closeness of particles, and we use the word here as a term of comparison, expressing the proportion or quantity of matter in one body, to the quantity in another. Repulsion is a force supposed to extend to a small distance round bodies, and prevent them from coming in actual contact. The repelling force of the particles of a fluid is small, and therefore, if a fluid be divided, it readily unites again. But if a hard substance be broken, the parts cannot be made to adhere, unless they be moistened or melted according to their nature. Water repels most bodies till they are wet. A small sewing needle will swim in a basin of water. Drops of water will roll on the leaves of many vegetables without wetting them. If a ball of light wood be dipped in oil, and afterwards dropped into water, the water will be repelled from the wood, and will form a channel round it. Density, therefore, is directly as the quantity of matter, and inversely as the magnitude of the body.

*The Attraction of Gravitation.*—Gravity is that force by which all the masses of matter tend towards each other, and which they exert at all distances. It is by this attraction that the heavenly bodies are retained in their several places, by their action on each other, and it is also by this that a stone dropped from a height falls to the surface of the earth. It is one of the laws of nature, that every particle of matter gravitates towards every other particle. The planets and comets all gravitate towards

the sun, and towards each other, as well as the sun towards them, and that in proportion to the quantity of matter in each. All terrestrial bodies tend towards the centre of the earth, consequently bodies fall every where perpendicular to its surface, and on opposite sides in opposite directions. As gravity acts upon all bodies in proportion to their quantities of matter, it is this attractive force that constitutes their weight. In all places equidistant from the centre of the globe, the force of gravity is equal. The force of gravity is greatest at the earth's surface, from whence it decreases both upwards and downwards. Upwards the force decreases as the square of the distance from the centre increases; but below the surface of the earth the force of gravity decreases, so that at the distance of half a semidiameter from the centre, it is but half what it is at the surface; at one-third of the semidiameter, one-third; and so on for any other assumed distances. Gravity and weight are, in particular circumstances, synonymous terms. We say such a piece of lead weighs a pound, but if by any means it could be carried 4000 miles above the surface of the earth, it would only weigh four ounces; and provided it could be removed 8000 miles above the earth, which is three times the distance from the centre that the surface is, it would weigh only one-ninth of a pound. Again, since the force of gravity downwards decreases as the distance from the surface increases, 16 ounces would weigh, at one-half the distance from the centre to the surface, only eight ounces, and so on for one-third, &c. Hence, a piece of metal, &c. weighing on the surface of the earth one pound, will

|                                   |                           |
|-----------------------------------|---------------------------|
| At the centre weigh .....         | 0                         |
| 1,000 miles from the centre ..... | $\frac{1}{4}$ of a pound. |
| 2,000 .....                       | $\frac{1}{2}$             |
| 3,000 .....                       | $\frac{3}{4}$             |
| 4,000 .....                       | 1                         |
| 8,000 .....                       | $\frac{1}{4}$             |
| 12,000 .....                      | $\frac{1}{9}$             |

**ATTRIBUTES**, in Theology, the several qualities or perfections of the Divine nature: in Logic, the predicates of any subject, or what may be affirmed or denied of any thing: in Painting and Sculpture, symbols added to several figures, to intimate their particular office and character. Thus, the *eagle* is an attribute of Jupiter; the *peacock*, of Juno; a *club*, of Hercules; a *trident*, and chariot with sea-horses, of Neptune; of Hope, an anchor; of Faith, a cross; &c.

**ATWOOD'S MACHINE**, (figure 119,) illustrates the doctrines of accelerated motion, by subjecting to experimental examination the quantity of matter moved, the measure of the force which moves it, the space described from quiescence, the time of description, and the velocity acquired. The theory of this instrument depends upon principles usually exhibited in dynamics.

1. *Of the Mass moved.*—In order to observe the effects of the moving force, which is the object of any experiment, the interference of all other forces should be prevented: the quantity of matter moved, therefore, considering it before any impelling force has been applied, should be without weight; for although it be impossible to abstract the natural gravity or weight from any substance whatever, yet the weight may be so counteracted as to be of no sensible effect in experiments. Thus, in the instrument constructed to illustrate this subject experimentally, AB represent two equal weights affixed to the extremities of a very fine and flexible silk line: this line is stretched over a wheel or fixed pulley *abcd*, moveable round an horizontal axis: the two weights, AB, being precisely equal and acting against each other, remain in equilibrium; and when the least weight is superadded to either, (setting aside the effects of friction,) it will preponderate. When AB are set in motion by the action of any weight *m*, the sum *A+B+m* would constitute the whole mass moved, but for the inertia of the materials which must necessarily be used in the communication of motion: these materials consist of, 1. The wheel *abcd*, over which the line sustaining A and B passes. 2. The four friction wheels, on which the axle of the wheel *abcd* rests: the use of these wheels is to prevent the loss of motion, which would be occasioned by the friction of the axle, if it revolved on an immoveable surface. 4. The line by which the bodies A

and B are connected, so as when set in motion to move with equal velocities. The weight and inertia of the line are too small to have sensible effect on the experiments; but the inertia of the other materials just mentioned constitutes a considerable proportion of the mass moved, and must be taken into account. Since, when A and B are put in motion, they must necessarily move with a velocity equal to that of the circumference of the wheel *abcd*, to which the line is applied; it follows, that if the whole mass of the wheels were accumulated in this circumference, its inertia would be truly estimated by the quantity of matter moved: but since the parts of the wheels move with different velocities, their effects in resisting the communication of motion to A and B by their inertia will be different; those parts which are furthest from the axis resisting more than those which revolve nearer, in a duplicate proportion of those distances. If the figures of the wheels were regular, from knowing their weights and figures, the distances of their centres of gyration from their axes of motion would become known, and consequently an equivalent weight, which being accumulated uniformly in the circumference *abcd*, would exert an inertia equal to that of the

wheels in their constructed form. But as the figures are wholly irregular, recourse must be had to experiment, to assign that equivalent quantity of matter, which being accumulated uniformly in the circumference of the wheel *abcd*, would resist the communication of motion to A in the same manner as the wheels. In order to ascertain the inertia of the wheel *abcd* with that of the friction-wheels, the weights AB being removed, the following experiment was made: A weight of thirty grains was affixed to a silk line, (the weight of which was not so much as  $\frac{1}{4}$ th of a grain, and consequently too inconsiderable to have sensible effect in the experiment;) this line being wound about the wheel *abcd*, the weight 30 grains by descending from rest communicated motion to the wheel, and by many trials was observed to describe a space of about  $38\frac{1}{2}$  inches in 3 seconds.

Fig. 120.

From these data the equivalent mass or inertia of the wheels will be known from this rule: Let a weight, P, (fig. 120,) be applied to communicate motion to a system of bodies by means of a very slender and flexible line going round the wheel *SLDIM*, through the centre of which the axis passes, (G being the common centre of gravity, R the centre of gravity of the matter contained in this line, and O the centre of oscillation.) Let this weight descend from rest through any convenient space *s* inches, and let the observed time of its descent be *t* seconds; then if *l* be the space through which bodies descend freely by gravity

in one second, the equivalent weight sought =  $\frac{W \times R \times S \times O}{S^2} =$

$\frac{P \times t^2 l}{s} - P$ . Here we have *p* = 30 grains, *t* = 3 seconds,

$l = 193$  inches,  $s = 38.5$  inches; and  $\frac{P \times l}{s} = P = \frac{30 \times 9 \times 193}{385}$

$- 30 = 1323$  grains, or  $2\frac{3}{4}$  ounces. This is the inertia equivalent to that of the wheel  $abcd$ , and the friction-wheels together; for the rule extends to the estimation of the inertia of the mass contained in all the wheels. The resistance to motion, therefore, arising from the wheels' inertia, will be the same as if they were absolutely removed, and a mass of  $2\frac{3}{4}$  ounces were uniformly accumulated in the circumference of the wheel  $abcd$ . This being premised, let the boxes A and B, fig. 119, be replaced, being suspended by the silk line over the wheel or pulley  $abcd$ , and balancing each other: suppose that any weight  $m$  be added to A, so that it shall descend, the exact quantity of matter moved, during the descent of the weight A, will be ascertained, for the whole mass will be  $A + B + m + 2\frac{3}{4}$  oz.

In order to avoid troublesome computations in adjusting the quantities of matter moved and the moving forces, some determinate weight of convenient magnitude may be assumed as a standard, to which all the others are referred. This standard weight in the subsequent experiments is  $\frac{1}{4}$  of an ounce, and is represented by the letter  $m$ . The inertia of the wheels being therefore  $= 2\frac{3}{4}$  ounces, will be denoted by  $11m$ . A and B are two boxes, constructed so as to contain different quantities of matter, according as the experiment may require them to be varied; the weight of each box, including the hook to which it is suspended,  $= 1\frac{1}{2}$  oz., or according to the preceding estimation, the weight of each box will be denoted by  $6m$ ; these boxes contain such weights as are represented by fig. 122, each of which weighs an ounce, so as to be equivalent to  $4m$ ; other

weights of  $\frac{1}{2}$  oz.  $= 2m$ ,  $\frac{1}{4}$   $= m$ , and aliquot parts of  $m$ , such as  $\frac{1}{8}$ ,  $\frac{1}{16}$ , may be also included in the boxes, according to the conditions of the different experiments hereafter described.

If  $4\frac{1}{2}$  oz. or  $19m$ , be included in either box, this, with the weight of the box itself, will be  $25m$ ; so that when the weights A and B, each being  $25m$ , are balanced in the manner above represented, their whole mass will be  $50m$ , which being added to the inertia of the wheels  $11m$ , the sum will be  $61m$ . Moreover, three circular weights, such as that which is represented at fig. 122, are constructed; each of which  $= \frac{1}{4}$  oz. or  $m$ : if one of these be added to A and one to B, the whole mass will now become  $63m$ , perfectly in equilibrio, and moveable by the least weight added to either, (setting aside the effects of friction,) in the same manner precisely as if the same weight or force were applied to communicate motion to the mass  $63m$ , existing in free space and without gravity.

2. *The moving Force.* Since the natural weight or gravity of any given substance is constant, and the exact quantity of it easily estimated, it will be convenient here to apply a weight to the mass A as a moving force: thus, when the system consists of a mass  $= 63m$ , according to the preceding description, the whole being perfectly balanced, let a weight  $\frac{1}{4}$  oz. or  $m$ , such as is represented in fig. 123, be applied on the mass A; this will communicate motion to the whole system: by adding a quantity of matter  $m$  to the former mass  $63m$ , the whole quantity of matter moved will now become  $64m$ ; and the moving force being  $= m$ , this will give the force which accelerates the descent of A  $= \frac{m}{64m}$ , or  $\frac{1}{64}$  part of the accelerating force

by which the bodies descend freely towards the earth's surface.

By the preceding construction, the moving force may be altered without altering the mass moved; for, suppose the three weights  $m$ , two of which are placed on A, and one on B, to be removed, then will A balance B. If the weights  $3m$  be all placed on A, the moving force will now become  $3m$ , and the mass moved  $64m$  as before, and the force which accelerates

the descent of A  $= \frac{3m}{64m} = \frac{3}{64}$  parts of the force by which

gravity accelerates bodies in their free descent to the surface. Suppose it were required to make the moving force  $2m$ , the mass moved continuing the same. In order to effect this, let the three weights, each of which  $= m$ , be removed; A and B will balance each other; and the whole mass will be  $61m$ : let  $\frac{1}{2}m$  fig. 123, be added to A, and  $\frac{1}{2}m$  to B, the equilibrium will still be preserved, and the mass moved will be  $62m$ ; now let  $2m$  be added to A, the moving force will be  $2m$ , and the mass moved  $64m$  as before; wherefore the force of acceleration  $= \frac{2}{64}$  part of the acceleration of gravity. These alterations in the moving force may be made with great ease and convenience in the more obvious and elementary experiments, there being no necessity for altering the contents of the boxes A and B; but the proportion and absolute quantities of the moving force and mass moved may be of any assigned magnitude, according to the conditions of the proposition to be illustrated.

3. *Of the Space described.*—The body A, fig. 119, descends in a vertical line; and a scale about 64 inches in length graduated into inches and tenths of an inch is adjusted vertically, and so placed that the descending weight A may fall in the middle of a square stage, fixed to receive it at the end of the descent: the beginning of the descent is estimated from 0 on the scale, when the bottom of the box A is on a level with 0. The descent of A is terminated when the bottom of the box strikes the stage, which may be fixed at different distances from the point 0; so that by altering the position of the stage, the space described from quiescence may be of any given magnitude less than 64 inches.

4. *The Time of motion,* is observed by the beats of a pendulum, which vibrates seconds; and the experiments, intended to illustrate the elementary propositions, may be easily so constructed, that the time of motion shall be a whole number of seconds: the estimation of the time, therefore, admits of considerable exactness, provided the observer takes care to let the bottom of the box A begin its descent precisely at any beat of the pendulum; then the coincidence of the stroke of the box against the stage, and the beat of the pendulum at the end of the time of motion, will shew how nearly the experiment and the theory agree together. There might be various mechanical devices thought of for letting the weight A begin its descent at the instant of a beat of the pendulum W: let the bottom of the box A, when at 0 on the scale, rest on a flat rod, held in the hand horizontally, its extremity being coincident with 0; by attending to the beats of the pendulum, and with a little practice, the rod which supports the box A may be removed at the moment the pendulum beats, so that the descent of A shall commence at the same instant.

5. *Of the Velocity acquired.*—It remains only to describe in what manner the velocity acquired by the descending weight A, at any given point of the space through which it has descended, is made evident to the senses. The velocity of A's descent being continually accelerated, will be the same in no two points of the space described. This is occasioned by the constant action of the moving force; and since the velocity of A at any instant is measured by the space which would be described by it, moving uniformly for a given time with the velocity it had acquired at that instant, this measure cannot be experimentally obtained, except by removing the force by which the descending body's acceleration was caused. In order to shew in what manner this is affected practically, let us again suppose the boxes A and B  $= 25m$  each, so as together to be  $= 50m$ ; now let  $m$ , fig. 121, be added to A, and an equal weight  $m$  to B, these bodies will balance each other, and the whole mass will be  $63m$ . If a weight  $m$  be added to A, motion will be communicated, the moving force being  $m$ , and the mass moved  $64m$ . In estimating the moving force, the circular weight  $= m$  was made use of as a moving force: but for the present purpose of shewing the velocity acquired, it will be convenient to use a flat rod, the weight of which is also  $= m$ . Let the bottom of the box A be placed on a level with 0 on the scale, the whole mass being as described above  $= 63m$ , perfectly balanced in equilibrio. Now let the rod, the weight of which  $= m$ , be placed on the upper surface of A; this body will descend along the scale precisely in the same manner as when the moving force was applied in the form of a circular weight. Suppose the mass A, (fig. 121.) to have descended by

constant acceleration of force of  $m$ , for any given time, or through a given space: let a circular frame be so affixed to the scale, contiguous to which the weight descends, that A may pass centrally through it, and that this circular frame may intercept the rod  $m$ , by which the body A has been accelerated from quiescence. After the moving force  $m$  has been intercepted at the end of the given space or time, there will be no force operating on any part of the system, which can accelerate or retard its motion: this being the case, the weight A, the instant after  $m$  has been removed, must proceed uniformly with the velocity which it had acquired that instant: in the subsequent part of its descent, the velocity being uniform, will be measured by the space described in any convenient number of seconds. Among other uses of the instrument, is the experimental estimation of the velocities communicated by the impact of bodies elastic and non-elastic; the quantity of resistance opposed by fluids, as well as for various other purposes. The properties of retarded motion are a part of the present subject, and may be necessary to shew in what manner the motion of bodies resisted by constant forces are reduced to experiment by means of the instrument above described, with as great ease and precision as the properties of bodies uniformly accelerated. A single instance will be sufficient: Thus, suppose the mass contained in the weights A and B, fig. 121, and the wheels to be  $61m$ , when perfectly in equilibrio; let a circular weight  $m$  be applied to B, and let two long weights or rods, each  $= m$ , be applied to A, then will A descend by the action of the moving force  $m$ , the mass moved being  $64m$ : suppose that when it has described any given space by constant acceleration, the two rods  $m$  are intercepted by the circular frame above described, while A, is descending through it, the velocity acquired by that descent is known; & when the two rods are intercepted, the weight will begin to move on with the velocity acquired, being now retarded by the constant force  $m$ ; and since the mass moved is  $62m$ , it follows that the force of retardation will be  $\frac{1}{2}$  part of that force whereby gravity retards bodies thrown perpendicularly upwards. The weight A will therefore proceed along the graduated scale in its descent with an uniformly retarded motion, and the space described, times of motion, and velocities destroyed by the resisting force, will be subject to the same measures as in the examples of accelerated motion above described. In the foregoing descriptions, two suppositions have been assumed, neither of which is mathematically true: but it may be easily shewn that they are so in a physical sense; the errors occasioned by them in practice being insensible.

Fig. 121.

1. The force which communicates motion to the system has been assumed constant; which will be true only on a supposition that the line, at the extremities of which the weights A and B, fig. 119, are affixed, is without weight. In order to make it evident that the line's weight and inertia are of no sensible effect, let a case be referred to, wherein the body A descends through 48 inches from rest by the action of the moving force  $m$ , when the mass moved is  $64m$ ; the time wherein A describes 48 inches is increased by the effects of the line's weight by no more than  $\frac{312}{10000}$ th parts of a second; the time of descent being 3.9896 seconds, when the string's weight is not considered, and the time when the string's weight is taken into account  $= 4.0208$  seconds; the difference between which is wholly insensible by observation.

2. The bodies have also been supposed to move in vacuo, whereas the air's resistance will have some effect in retarding their motion: but as the greatest velocity communicated in these experiments cannot much exceed that of about 26 inches in a second, (suppose the limit 26.2845,) and the cylindrical boxes being about  $1\frac{1}{2}$  inches in diameter, the air's resistance can never increase the time of descent in so great proportion as that of 240:241; its effects therefore will be insensible in experiment. The effects of friction are almost wholly removed by the friction-wheels; for when the surfaces are well polished and free from dust, &c. if the weights A and B be balanced in perfect equilibrio, and the whole mass consists of  $63m$ , according to the example already described, a weight of  $1\frac{1}{2}$  grain, or at most 2 grains, being added either to A or B, will communicate motion to the whole; which shews that the effects of friction will not be so great as a weight of  $1\frac{1}{2}$  or 2 grains. In some cases, however, especially in experiments relating to retarded motion, the effects of friction become sensible; but may be very readily and exactly removed by adding a small weight of 1.5 or 2 grains to the descending body, taking care that the weight added is such as is in the least degree smaller than that which is just sufficient to set the whole in motion, when A and B are equal, and balance each other before the moving force is applied.—The foregoing article is taken nearly verbatim from Dr. Gregory's Mechanics; and the instrument may be purchased for £28, at Harris's, 50, High Holborn.

AUGUST, the eighth month of the year, when we have in season—of Meat: beef, mutton, veal, lamb, buck, venison, &c. Poultry: pullets, fowls, chickens, green geese, turkey poults, ducklings, leverets, rabbits, pigeons, pheasants, wild ducks, wheatears, plovers. Fish: cod, haddock, flounders, plaice, skate, thornback, mullets, mackarel, herrings, pike, carp, eels, lobsters, crawfish, prawns, oysters. Vegetables: carrots, turnips, potatoes, radishes, onions, garlic, shalots, scorzonera, salsific, peas, beans, kidney beans, mushrooms, artichokes, cabbages, cauliflowers, sprouts, beets, celery, endive, pinocha, parsley, lettuce, salads, thyme, marjoram, sweet herbs, savoy. Fruit: peaches, nectarines, plums, cherries, apples, pears, grapes, figs, filberts, mulberries, strawberries, gooseberries, currants, melons, pineapples.

*The Botanical Kalendar for August.*—Many seeds and herbaceous vegetables ripen in this month, and most of the culinary crops raised in the open garden, are now in perfection. Insects, especially the winged tribes of butterflies, abound, and the gardener should destroy them, or collect them for specimens. Numbers of beautiful insects may thus be gathered, even while at work. The young martins begin to congregate; bees kill their drones; numerous birds resume their spring notes; the goatsuckers and young owls hoop and make a noise in the evenings. Melilot, yellow succory, burdock, tobacco, wild clary, meadow rice, plowman's spikenard, mallows, hollyhocks, lobelias, crocuses, &c. are in flower. Bread corns ripen, and the earlier varieties of all the kernel fruits ripen. Sow turnips for a main crop early in this month, salads, radishes, parsley, spinach, carrots, endive, chervil, for winter and spring crops; cauliflowers to stand over winter, in sheltered borders and under frames. Propagate by slips and cuttings; transplant leeks and perennials; hoe, thin, weed, and stir winter crops; clear off all crops the moment they are done with; gather pickling cucumbers and ripe seeds. Plant strawberries; prune, regulate, and train summer shoots of wall trees and espaliers. Mat up all fruits on north walls, intended to be preserved till late in

autumn. Gather gooseberries, currants, and all ripe fruit. Plant evergreens, repair lawns, destroy ferns, nettles, and weeds about park scenery and fences. Take up bulbs, transplant biennials, &c.

**AULA REGIS**, a court established by William the Conqueror, in his own hall, and composed of the great officers of state. The 11th article of Magna Charta regulates this court, which is now established in Westminster Hall. See **KING'S BENCH**.

**AULIC COUNCIL**, composed of the great officers of the German empire, always follows the emperor's court, but ceases on his death; whereas the imperial chamber of assize is perpetual, and represents not only the deceased emperor, but the whole Germanic body. **AULIC**, in the Sorbonne, &c. is an act which a young divine maintains, upon being admitted a doctor of divinity. It commences by an harangue of the chancellor, addressed to the young doctor, after which he receives the cap, and presides at the aulic or disputation.

**AURIGA**, in Astronomy, the Waggoner or Charioteer, a mere type or scientific symbol of that beautiful fable which is given us of Phaeton; or, more properly, he may be the attendant of Phœbus at that remote period when Taurus opened the year. The boundaries and contents of this constellation are these:—North by Camelopardalis, east by Lynx, Herschel's Telescope, and Gemini; south by Taurus, and west by Perseus. Auriga contains 66 stars, one of the 1st magnitude, two of the 2d magnitude, nine of the fourth, &c. The declination generally is  $45^{\circ}$  north, and its right ascension  $75^{\circ}$ . A large portion of this constellation is always above the horizon to the British isles, and consequently to all places in corresponding latitudes. The Charioteer's head passes vertically over England and Ireland. The most remarkable star in this constellation, and indeed in this quarter of the firmament, is Capella, of the 1st magnitude, situated on Auriga's left, or western shoulder; its north declination is  $45^{\circ} 47' 18''$ , and its right ascension  $75^{\circ} 51' 3''$ , or 5 hours 3 minutes in time. Capella culminates for the first day of each month in the year, as follows; and by adding 12 hours to the culminating of this or any other star, we determine the time it is on the meridian under the pole. Meridian altitude,  $84^{\circ} 16' 18''$  north.

**AURORA BOREALIS**, or *Northern Twilights*, or streamers, may be defined an electrical phenomena, or aerial electricity, which is seen generally in the winter time, and in frosty weather and clear evenings, in the Hyperborean regions of the skies. This meteor assumes every variety of tint that embellishes the iris or rainbow, but wears generally a fiery and purple hue. Its appearance is indeed now so generally known, even in this country, that a more particular description is not requisite: but it may be just observed, that as we only see the extremities of this brilliant phenomenon, we can have but a faint idea of its real splendour in the arctic regions, where it appears in perfection, and proves a great solace to the inhabitants amidst the gloom of the long winter nights. In some parts of Siberia, particularly, this beautiful meteor is constantly exhibited from October to Christmas, and its radiating beams in those parts are remarkably bright.

Captain Ellis, who wintered on the western coast of Hudson's Bay in North America, observes, that no sooner does the sun disappear in those regions, than the aurora borealis diffuses a thousand different lights and colours over the whole concavity of heaven, with such resplendent beauty, that even the full moon cannot eclipse their lustre. It was for a long time a matter of doubt whether this meteor made its appearance in the southern hemisphere; but Mr. Foster, who went round the world with Captain Cook, ascertained the fact, Feb. 17, 1773, in lat.  $58^{\circ}$  south, though it appeared with phenomena somewhat different from ours. Concerning the cause of the aurora borealis, many conjectures have been formed; but that which seems to be supported by the most specious reasoning ascribes its origin to electricity. It is supposed, that most of the

extraordinary meteors and appearances in the skies, related as prodigies by historians, *e. g.* battles, and the like, may be probably enough reduced to the class of *auroræ boreales*. In certain states of the atmosphere these phenomena have sometimes assumed the colour of blood, and made a dreadful appearance. At these times the rustic sages became prophetic, and terrified the gazing spectators with the dread of wars, pestilence, and famine: even persons more enlightened supposed them to be portentous of great events, and timid imaginations shaped them into aerial conflicts.

Captain Franklin enumerates aurora Borealis, at one time, in form of a bright arch, extending across the zenith, in a north-west and south-east direction,—at another, it was extremely brilliant, its coruscations darting at times over the whole sky, and assuming various prismatic colours, of which violet and yellow were predominant,—again, its appearances were greatly diversified, and its motion extremely rapid, its coruscations occasionally concealed stars of the first magnitude in passing over them; once a stream of light illumined the under surface of some clouds as it passed along:—these appearances were visible in the winter. In the spring the aurora was very brilliant and variable; at one time exhibiting illumined beams issuing from the horizon in the north, east, and west points, and directed towards the zenith; in a few seconds these disappeared, and a complete circle was displayed, bounding the horizon at an elevation of  $15^{\circ}$ . There was a quick lateral motion, in the attenuated beams of which this zone was composed. Its colour was pale yellow, with an occasional tinge of red. On another occasion, the aurora borealis appeared from north-west to south-east, in an arch across the zenith, which afterwards gave place to a beautiful corona borealis.

In the month of Jan. 1821, the aurora appeared with more or less brilliancy on 28 nights, and for many days together the resplendent moon whirled in circles round the heavens, shining with undiminished lustre, and scarcely disappearing below the horizon during the twenty-four hours.

But Captains Franklin and Parry, and Dr. Richardson, who have added to our already accumulated facts relative to this curious phenomenon, have thrown no light on its theory. Now it is known that the luminous beams of this meteor are all cylindrical, and, over a certain extent of country, parallel to one another. And if these cylindrical beams are magnetic, and parallel to the dipping needle at the places over which they appear, then is the aurora borealis a purely magnetic phenomenon, whose beams are governed by the earth's magnetism. And this is the more probable, as the distance of these beams from the earth is nearly equal to their length; the rainbow-like arches being about 150 miles above the earth's surface.

Lieutenant Back, the brave companion of Captain Franklin, relates that, in the same journey to the Polar sea, he imagined more than once, whilst listening attentively in the silence of midnight on the wilds of the American lakes, and gazing on the fantastic beauties of the aurora borealis, he heard a rustling noise, like that of autumnal leaves stirred by the wind. This, however, he thinks was but illusion. The aurora was very sluggish and dim, otherwise he has little doubt he should have ascertained this yet undecided fact. One of the partners of the North West company affirmed, however, that on one occasion amidst these solitudes, he saw the coruscations of the aurora so vivid and low, that the Canadians fell on their faces, fearing they should be killed: he himself threw away his gun and his knife, that he might not attract the flashes, which were within two feet of the earth, flitting along with incredible swiftness, and moving parallel to its surface, making a loud rustling noise like the waving of a flag in a strong breeze. On another occasion these lights rose about north-west, divided into three bars, diverging at equal distances, as far as the zenith, and then converging till they met in the opposite horizon; there were some flashes emitted at right angles to the bars. At another time the coruscations were so bright as to discover eight wolves prowling about the voyagers. Heavy storms were at some places generally anticipated by the activity of the aurora borealis; though not invariably so in other parts of the country.

And analogous to this are those luminous arches so beautifully described by Thomson as

— Silent from the north

A blaze of meteors shoots; ensweeping first  
The lower skies, they all at once converge  
High to the crown of heaven, and all at once  
Relapsing quick, as quickly reascend,  
And mix, and thwart, extinguish and renew,  
All ether coursing in a maze of light.

In March, 1774, a very beautiful luminous arch was seen at Buxton. It was white, inclining to yellow; and its breadth in the crown apparently equal to that of the rainbow. As it approached the horizon, each leg became gradually broader. It was stationary, and free from any sensible coruscations. Its direction was from north-east to south-west; and its crown or most elevated part not far from the zenith. This phenomenon lasted about half an hour. The grandest spectacle of this kind, seen in Great Britain, was observed at Leeds, on the 12th of April, 1783, between nine and ten at night. A broad arch of a bright pale yellow, with an apparent breadth of about  $15^\circ$ , arose in the heavens, and passed considerably south of the zenith; by its varied density, it appeared to consist of small columns of light, with a sensible motion. After about ten minutes, innumerable bright coruscations shot out at right angles from its northern edge, elongating themselves till they had nearly reached the northern horizon. As they descended, their extremities were tipped with an elegant crimson, like that produced by the electric spark in an exhausted tube. After some time this beautiful northern light ceased to shoot, and, forming a range of bright yellow clouds, extended horizontally about the fourth of a circle; its greatest portion, which darted from this arch northwards, as well as the cloud-like and more stationary aurora, became so dense as to hide the stars from view. The moon was eleven days old, and shone brightly during this scene, but did not eclipse the splendour of these coruscations. The wind was in the north, a little to the east. A similar phenomenon was observed at Leeds on the 26th of the same month. From a mass or broad column of light in the west, issued three luminous arches, each of which made a different angle with the horizon. They had not been viewed many minutes when they were rendered invisible by a general blaze of aurora borealis, which possessed the space just before occupied by these arches.

**AURUM**, Gold. This most precious of all the metals is usually found in a perfectly pure state, possessing a fine rich yellow colour, and a degree of ductility altogether incredible. By far the most copious supplies occur in alluvial soils, situated along the foot of large ranges of mountains, from which it is apparently washed down by the rivers. It occurs likewise, though in smaller quantities, in veins and beds diffused through granite, gneiss, and other primitive rocks; also in porphyry and sand-stone; and it is generally accompanied with quartz and iron pyrites. Alluvial gold is found in the district of Leadhills in Scotland; and it is reported that, in the time of queen Elizabeth, the metal was there collected to the amount of £100,000. It appears also in Glen Turret, in Perthshire, some parts of Cornwall, and in Ireland, near Arklow, in the county of Wicklow. In all those places, however, it presents itself rather as an object of curiosity than of any real value. The same may be said of the veins which occur in primitive rocks in Salzburg, the Tyrol, Transylvania, and at Edelfors, in Sweden, as well as of the golden sands poured down by the Danube, Rhine, Tagus, and other European rivers. Africa is much more prolific of this valued metal. All the streams which flow from the great mountain-ranges in the centre of that continent appear to impregnate their sands with gold. It is found most copiously in Bambouk, Manding, Wangara, and the countries behind the Gold coast. A large quantity is also collected in the mountains behind Mosambique. The islands of Sumatra, Borneo, and Celebes, in the East Indies, contain large stores of alluvial gold, the working of which has been so much improved by the industry of the Chinese, as to render those regions nearly independent of supply from the west. Nothing on the globe, however, can equal the abundance in which the gold occurs throughout the vast regions of South

America. The Mexican gold is chiefly alluvial, but partly found in primitive mountains, and mixed with silver, in the mines of that metal. The situation of the Peruvian gold is nearly similar, but the mines do not pay the expense of working, and the chief riches here, as elsewhere, is obtained by washing. The ample supply of gold which is drawn from Brazil is entirely alluvial, deposited along the foot of that great range of mountains which forms the western frontier of that settlement. Humboldt calculates the entire annual produce of the Spanish colonies at 25,000lbs. troy, and that of the Portuguese at somewhat above 20,000. Gold occurs in three other forms, called by Werner brass yellow, grayish yellow, and electrum, or argentiferous native gold. These occur in different parts of Europe, but in such small quantity as not to deserve much consideration here. The ductility and malleability of gold is so great, that its limits are unknown. The weight of a single grain of fine gold leaf will cover 57 square inches. Calculating the specific gravity of the metal with this admeasurement, we find, that 282,000 of these leaves put together would only be an inch thick. It is nevertheless evident that gold is capable of much greater extension, as the gold-beaters are obliged to alloy the gold with copper, to make it hard enough to pass over the irregularities in the skins, which would otherwise pass round them. It is likewise proved by the silver-gilt wire used for lace-making, which is drawn from an ingot of silver previously gilded. Calculating the length and circumference of the wire thus drawn, it is found that the weight of a grain of gold thus employed, has spread itself over a surface of twelve times greater extent than is done by the gold-beaters in making it into leaves; therefore it follows, if the gold could be made into leaves as thin as the covering upon the silver wire, that it would take 3,384,000 leaves to make an inch in thickness.

**AURUM MUSIVUM**, used by the japanners, and for varnished works, as snuff-boxes, coaches, &c. has all the beautiful appearance of gold in powder. Amalgamate twelve parts of the purest tin with three parts of mercury; the amalgam is then triturated in a stone mortar with seven parts of flowers of sulphur and three parts of sal ammoniac. The mixture is next put into a matrass, and the whole exposed to a gentle sand-heat, until no more white fumes arise. When, upon this, the heat is somewhat raised, cinnabar sublimes, together with some oxygenated muriate of tin: while at the same time, the remaining tin and sulphur unite, forming the aurum musivum, exhibiting a golden yellow and flaky and scaly matter, of a metallic lustre. The main point in this process is the proper regulation of the fire: when too strong, the operation does not succeed; and instead of aurum musivum, the common sulphuret of tin is obtained.

**AUSTRAL**, the same as *southern*; thus we say, *Australis Corona*, *Australis Piscis*, for Southern Crown, and Southern Fish. See **CORONA** and **PISCIS**.

**AUTOMATON**, a seemingly self-moving machine; or one so constructed, by means of weights, levers, pulleys, springs, &c. as to move for a considerable time, as if it were endued with animal life. And according to this description, clocks, watches, and all machines of that kind, are automata. It is said that Archytas of Tarentum, four hundred years before Christ, made a wooden pigeon that could fly; that Archimedes also made similar automata; that Regiomontanus made a wooden eagle that flew forth from the city, met the emperor, saluted him, and returned; also that he made an iron fly, which flew out of his hand at a feast, and returned again after flying about the room; that Dr. Hooke made the model of a flying chariot, capable of supporting itself in the air. Many curious and surprising automata have been witnessed in the present age: thus, we have seen figures that could write, and perform many other actions in imitation of animals: M. Vaucanson made a figure that played on the flute; the same gentleman also made a duck, which was capable of eating, drinking, and imitating exactly the voice of a natural one; and, what is still more surprising, the food it swallowed was evacuated in a digested state, or considerably altered on the principles of solution; also the wings, viscera, and bones, were formed so as strongly to resemble those of a living duck; and the actions of eating and drinking shewed the strongest resemblance, even to the muddling the water with its bill. M. le Droz, of Neufchatel, has

also executed some very curious pieces of mechanism: one was a clock, presented to the king of Spain, which had, among other curiosities, a sheep that imitated the bleating of a natural one, and a dog watching a basket of fruit, that barked and snarled when any one offered to take it away; besides a variety of human figures, exhibiting motions truly surprising. The automaton chess-player is yet more surprising. This wonderful piece of mechanism, the invention of M. de Kemplin, an Hungarian gentleman, has for many years lain dormant. It was brought to England in the year 1817, and exhibited in the great room, Spring Gardens, London, and in other places, to the admiration and satisfaction of thousands. We shall here give a description of its mechanism and operations. The room, where it is exhibited, has an inner apartment, within which appears the figure of a man, as large as life, dressed after the Turkish fashion, sitting behind a chest three and a half feet in length, two feet in breadth, and two feet and a half in height, to which it is attached by a wooden seat. The chest is placed upon four castors; and, together with the figure, may be moved to any part of the room. On the plain surface, formed by the top of the chest, in the centre, is a raised immovable chess-board, upon which the figure has its eyes fixed; its right arm and hand being extended on the chest, and its left arm holding a Turkish tobacco-pipe. The exhibitor begins by wheeling the chest to the entrance of the apartment within which it stands, and in face of the spectators. He then opens certain doors in the chest, two in front, and two at the back, at the same time pulling out a long shallow drawer at the bottom, which contains the chess-men, a cushion for the arm of the figure to rest upon, and some counters. Two lesser doors, and a green cloth screen, contrived in the body of the figure, and its lower parts, are likewise opened, and the Turkish robe which covers them is raised; so that the construction both of the figure and chest internally is displayed. In this state the automaton is moved round for the examination of the spectators; and to banish all suspicion that any living thing is concealed within any part of it, the exhibitor introduces a lighted candle into the body of the chest and figure, by which the interior of each is, in a great measure, rendered transparent, and the most secret corner is shewn. Here it may be observed, that the same precaution to remove suspicion is used, if requested, at the close as at the commencement of a game of chess with the automaton. The chest is divided, by a partition, into two unequal chambers. That to the right of the figure is the narrowest, and occupies scarcely one-third of the body of the chest. It is filled with little wheels, levers, cylinders, and other machinery used in clock-work. That to the left contains a few wheels, some small barrels with springs, and two quarters of a circle placed horizontally. The body and lower parts of the figure contain tubes, which seem to be conductors to the machinery. After a sufficient time, during which each spectator may satisfy his scruples and his curiosity, the exhibitor re-closes the doors of the chest and figure, and the drawer at bottom; makes some arrangements in the body of the figure; winds up the works with a key inserted into a small opening on the side of the chest; places a cushion under the left arm of the figure, which now rests upon it; and invites any individual present to play a game of chess. In playing a game, the automaton makes choice of the white pieces, and always has the first move. These are small advantages towards winning the game, which are cheerfully conceded. It plays with the left hand, the right arm and hand being constantly extended on the chest, behind which it is seated. This slight incongruity proceeded from absence of mind in the inventor, who did not perceive his mistake till the machinery of the automaton was too far completed to admit of the mistake being rectified. At the commencement of a game, the automaton moves its head, as if taking a view of the board; the same motion occurs at the close of a game. In making a move, it slowly raises its left arm from the cushion placed under it, and directs it towards the square of the piece to be moved. Its hand and fingers open on touching the piece, which it takes up, and conveys to any proposed square. The arm then returns with a natural motion to the cushion, upon which it usually rests. In taking a piece, the automaton makes the same motions of the arm

and hand to lay hold of the piece, which it conveys from the board; and then, returning to its own piece, it takes it up, and places it on the vacant square. These motions are performed with perfect correctness; and the dexterity with which the arm acts, especially in the delicate operation of castling, seems to be the result of spontaneous feeling, bending at the shoulder, elbow, and knuckles, and cautiously avoiding to touch any other piece than that which is to be moved, nor ever making a false move. After a move made by its antagonist, the automaton remains for a few moments inactive, as if meditating its next move; upon which the motions of the left arm and hand follow. On giving check to the king, it moves its head as a signal. When a false move is made by its antagonist, which frequently occurs through curiosity to observe in what manner the automaton will act, (as, for instance, if a knight be made to move like a castle,) the automaton taps impatiently on the chest with its right hand, replaces the knight on its former square, and, not permitting its antagonist to recover his move, proceeds immediately to move one of its own pieces, thus appearing to punish him for his inattention. The little advantage in play which is hereby gained, makes the automaton more a match for its antagonist; and seems to have been contemplated by the inventor as an additional resource towards winning the game. —It is of importance that the person matched against the automaton should be attentive, in moving a piece, to place it precisely in the centre of its square; otherwise, the figure, in attempting to lay hold of the piece, may miss its hold, or even sustain some injury in the delicate mechanism of the fingers. When the person has made a move, no alteration in it can take place; and if a piece be touched, it must be played somewhere. This rule is strictly observed by the automaton. If its antagonist hesitate to move for a considerable time, it taps smartly on the top of the chest with the right hand, which is constantly extended upon it, as if testifying impatience at his delay. During the time that the automaton is in motion, a low sound of clock-work is heard, which ceases soon after its arm returns to the cushion, and then its antagonist may make his move. The works are wound up at intervals, after ten or twelve moves, by the exhibitor, who is usually employed in walking up and down the apartment in which the automaton is shewn; approaching the chest however, from time to time, especially on its right side.

**AUTUMN**, the third season of the year: this begins at the descending equinox, which, in the northern hemisphere, is when the sun enters the sign *Libra*, about the twenty-second of August, and ends about the same day in December.

**AUTUMNAL Equinox**, the time when the sun enters the descending point of the ecliptic, where it crosses the equinoctial.

**AUTUMNAL Point**, the point of the ecliptic answering to the autumnal equinox.

**AUTUMNAL Signs**, are the signs *Libra*, *Scorpio*, *Sagittarius*, through which the sun passes during autumn.

**AVIARY**, a place set apart for rearing and feeding birds, which should be so large as to afford the birds some scope to fly about, and if turfed, there will be no appearance of dirt. Good stout small net, doubled, makes a good fence for an aviary; but wire is much better.

**AVOIDANCE**, in the Canon Law, is when a benefice becomes void of an incumbent, which happens either in fact, as by the death of the person; or in law, as by cession, deprivation, resignation, &c. In the first of these cases the patron must take notice of the avoidance at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron in order to prevent what is termed an elapse.

**AVOIRDUPOIS**, the weight for the larger and coarser commodities; such as groceries, lead, &c. Apothecaries buy by avoirdupois, but sell by troy weight. The proportion of a pound avoirdupois to a pound troy is as 17 to 14.

**AVOWEE**, one who has a right to present to a benefice. He is so called in contradistinction to those who only have the lands to which the advowson belongs, for a term of years, or by virtue of intrusion or disseisin.

**AVOWRY**, in Law, is when a person distrained sues out a replevin; for then the distrainer must avow and justify his plea, for distraining which is called his avowry.

**AXIOM**, a self-evident truth, or a proposition, the truth of which is perceived at first sight. Thus, that a whole is greater than a part; that a thing cannot be, and not be, at the same time; and that from nothing, nothing can arise; are self-evident truths, or axioms. Axiom is also an established principle in some art or science. Thus, it is an axiom in geometry, that things which are equal to the same thing, are equal to each other; that if to equal things, equal things be added, the wholes will be equal, &c.

**AXIS**, in Astronomy, an imaginary right line, supposed to pass through the earth, sun, planets, satellites, &c. and about which they perform their respective diurnal rotations. The earth and planets, in their progress through the annual orbit, move in such a manner that the axis of each always keeps parallel to itself, or points to the same parts of the heavens. The axis of the earth is inclined to the ecliptic in an angle of nearly  $66\frac{1}{2}^{\circ}$ , a position which is well adapted for promoting the fertility of the earth, and rendering it habitable. Dr. Keill has pointed out many advantages which result from this inclination of the axis, particularly in ripening the fruits of the earth; and he has proved the truth of much that was advanced by Kepler to the same effect. Among other curious particulars, Keill has shewn, that all who live beyond  $45^{\circ}$  of latitude, and have greatest need of the sun's heat, have more of it during the whole year than if the equator and ecliptic coincided; whereas they who live between the equator and  $45^{\circ}$  of latitude, and are rather too much exposed to the sun than too little, have, on account of the present inclination, less of the sun's heat than if the earth were in the position of a right sphere.

**AXIS** of the *Horizon*, *Equator*, &c. is a right line drawn through the centre of the respective circle, perpendicular to its plane.

**AXIS**, in Geometry, the straight line in a plane figure, about which it revolves, to produce or generate a solid. Thus, if a semicircle be moved round its diameter at rest, it will generate a sphere, whose axis is that diameter. And if a right-angled triangle be turned about its perpendicular at rest, it will describe a cone, whose axis is that perpendicular.

**AXIS** is yet more generally used for a right line conceived to be drawn from the vertex of a figure to the middle of the base. So the

**AXIS** of a *Circle* or *Sphere*, is any line drawn through the centre, and terminated at the circumference, on both sides.

**AXIS** of a *Cone*, is the line from the vertex to the centre of the base.

**AXIS** of a *Cylinder*, is the line from the centre of the one end to that of the other.

**Transverse AXIS**, in the *ellipse* and *hyperbola*, is the diameter passing through the two foci, and the two principal vertices of the figure. In the hyperbola it is the shortest diameter, but in the ellipse it is the longest.

**Conjugate AXIS**, or **Second AXIS**, in the *ellipse* and *hyperbola*, is the diameter passing through the centre, and perpendicular to the transverse axis. It is the shortest of all the conjugate diameters.

**AXIS** of a *Curve Line*, is still more generally used for that diameter which has its ordinates at right angles to it, when that position is possible.

**AXIS**, in Mechanics, a certain line about which a body may turn. Axes are of various kinds; as,

**AXIS** of a *Balance*, the line upon which it moves or turns.

**AXIS** of *Rotation*, the line about which a body really revolves, when it is put in motion. The impulse given to a homogeneous sphere, in a direction which does not pass through its centre, will cause it to revolve constantly round the diameter, which is perpendicular to a plane passing through its centre, and the line of direction of the impressed force. New forces acting on all its parts, and of which the result passes through its centre, will not change the parallelism of its axis of rotation. Thus it is, that the axis of the earth remains always nearly parallel to itself in its revolution round the sun, without its being necessary to suppose, with Copernicus, an annual motion of the poles of the earth round those of the ecliptic. If the body possess a certain figure, its axis of rotation may change every instant. The determination of these changes,

whatever may be the forces acting on the bodies, is one of the most interesting problems of mechanics respecting hard bodies, on account of its connexion with the precession of the equinoxes, and the libration of the moon. The solution of this problem has led to a curious and very useful result; namely, that in all bodies there exist three axes perpendicular to each other, round which the body may turn uniformly when not solicited by external forces. On this account, these axes are properly called principal axes of rotation.

**AXIS** of *Oscillation*, is a line parallel to the horizon, passing through the centre, about which a pendulum vibrates, and perpendicular to the plane in which it oscillates.

**AXIS** in *Peritrochio*, one of the five mechanical powers, consisting of a peritrochium or wheel, and moveable together with it about its axis. The power is applied at the circumference of the wheel, and the weight is raised by a rope that is gathered up on the axis while the machine turns round. The power may be conceived as applied at the extremity of the arm of a lever, equal to the radius of the wheel; and the weight as applied at the extremity of a lever, equal to the radius of the axis; only those arms do not meet at one centre of motion as in the lever, but in place of this centre we have an axis of motion, viz. the axis of the whole machine.

**AXIS**, in Optics: **Optic axis**, or **visual axis**, is a ray passing through the centre of the eye, or falling perpendicularly on the eye.

**AXIS** of a *Lens*, or *Glass*, is the axis of the solid of which the lens is a segment. Or the axis of a glass, is the line joining the two vertices or middle points of the two opposite surfaces of the glass.

**AXIS** of a *Magnet*, is a line passing through the middle of a magnet lengthwise, in such a manner as that, however the magnet is divided, provided the division is made according to a plane in which such line is found, the magnet will be cut or separated into two loadstones; and the extremes of such lines are called the poles of the magnet.

**AZIMUTH**, an Arabic term in Astronomy, signifying an arc of the horizon intercepted between the meridian of the place, and the vertical circle passing through the centre of an object, and is equal to an angle of the zenith, formed by the said meridian and vertical circle, which is measured by the fore-mentioned arc. The Azimuth is reckoned eastward in the morning, and westward in the afternoon, and is usually estimated to the north or south, as it is nearer to one or other of those points: thus, if it be found that the vertical circle which passes through the zenith, intersects the horizon exactly between the east and the south, then the star's azimuth is said to be  $45^{\circ}$  eastward of the south; or it is the complement to the eastern or western amplitude.

To find the *Azimuth*, at the *Time of the Equinox*, trigonometrically, Say,

As radius is to the tangent of the latitude,

So is the tangent of the altitude of the sun or star

To the cosine of the azimuth from the south.

To find the azimuth of a sun or star at any other time, the reader may consult any elementary treatise on astronomy.

**Magnetical AZIMUTH**, an arch of the horizon contained between the azimuth circle of the celestial object and the magnetical meridian; or it is the apparent distance of the object from the north or south point of the compass. This is found by observing the object with an azimuth compass, when it is about  $10^{\circ}$  or  $15^{\circ}$  high, either in the forenoon or afternoon.

**AZIMUTH Compass**, fig. 125, is a compass used at sea for finding the sun's magnetical azimuth; or, more properly, to take the bearing of any celestial object, when it is in or above the horizon, in order to find from the magnetical azimuth, or amplitude, the variation of the needle. The object is viewed through the upright slits or sights, and the bearing is read off on the card, which is divided into degrees, &c.

**AZIMUTH Circles**, called also vertical circles, are great circles of the sphere, intersecting each other in the zenith and nadir, and cutting the horizon at right angles.

**AZIMUTH Dial**, is a dial whose stile, or gnomon, is at right angles to the plane of the horizon.

**AZURE**, in a general sense, the blue colour of the sky; in Painting, a fine blue colour extracted from cobalt and lapis lazuli; but the colour extracted from the latter, is called ultramarine. See COLOURS.

**AZURE**, in Heraldry, the blue colour in the arms of any person below the rank of a baron. In the escutcheon of a noble-

man it is called sapphire, and in that of a sovereign prince Jupiter. In Engraving, this colour is expressed by lines drawn horizontally. This colour may signify justice, perseverance, and vigilance; when compounded with

|         |                          |               |
|---------|--------------------------|---------------|
| Or,     | } <i>it signifies,</i> } | Cheerfulness. |
| Argent, |                          | Vigilance.    |
| Gules,  |                          | Readiness.    |
| Ver,    |                          | Enterprise.   |
| Pur,    |                          | Goodness.     |
| Sab,    |                          | Sorrow.       |

## B.

### B A C

**BAC**, in Navigation, a praam or ferry boat; in Brewing, a beer cooler, a large shallow tub; in Distillery, fermenting tubs, are called bacs. And a bac-maker is a cooper, who makes liquor-bacs, underbacs, coolers, mashtubs, working tuns, &c.

**BACCHARIS**, ploughman's spikenard.

**BACK PAINTING**, the method of painting mezzotinto prints, painted on plate or crown glass with oil colours, thus:—the print and glass are to be of one size: the print is soaked in water two hours or longer, till thoroughly moistened; then put between two sheets of clean paper to be dried; the glass is warmed gently, and covered with Strasburgh turpentine: the plate laid on it, and rubbed down closely. Then the whole of the paper is rubbed off with the palm of the hand, but the print, like a thin film, is left upon the glass, and set by to dry. When dry it is varnished with white transparent varnish, and then coloured, or painted with oil-colours, tempered very stiffly; the shadows of the engraving being generally sufficiently deep for the picture.

**BACK-STAFF**, an instrument invented by captain Davis for a sea quadrant, and is so named because the back of the observer is turned towards the sun when using the instrument.

**BACK-STAYS**, are long ropes extending from the top-mast heads to both sides of the ship, where they are extended to the channels. Their use is to second the efforts of the shrouds in supporting the mast when strained by a weight of sail. They are usually distinguished into breast back-stays, after back-stays, and shifting back-stays; the first being intended to sustain the mast when the ship sails upon a wind; or, in other terms, when the wind acts upon a ship sideways; the second is to enable her to carry sail when the wind is farther aft; and the third kind take their name from being shifted or changed from one side to the other, as occasion requires. There are also back-stays to the top-gallant-masts.

**BACON, ROGER**, a Franciscan friar, born near Ilchester in Somersetshire, in 1214, and died in 1294. This bright luminary of the thirteenth century, was also a great linguist and grammarian, well versed in the theory of perspective and optics, knew the use of convex and concave glasses, and is said to have been the inventor of gunpowder, at least so far as related to its explosive power: he also understood the erroneous principle of the calendar, and assigned the cause, and proposed the remedy: he possessed great knowledge in the medical art, and was an able mathematician, metaphysician, and theologian. His great learning, however, subjected him to the persecution of his ignorant brethren, who accused him of having dealings with the devil, and he was in consequence confined for ten years, during which time he is said to have prosecuted his studies with the same ardour as before, and with the greatest possible success.

**BACON, FRANCIS**, Baron of Verulam, Viscount of St. Alban's, and Lord High Chancellor of England under James I. was born in 1560, and died in 1626; was one of those extraordinary geniuses, who, by giving a new direction to the study of philosophy, have most contributed to the advancement of the

### B A L

sciences. He clearly perceived the imperfection of the philosophy of the old school, and pointed out the only means of reforming it, by proceeding from facts to theories, and by means of experiments to the discovery of the laws of nature. The baron was not, however, immaculate in his office of chancellor; he was impeached for bribery and corruption, found guilty by his peers, and fined £40,000. Alas! that the "prophet of arts" should have stooped to receive gifts for the discharge of his duties!

**BAIL**, is used in our common law to signify the freeing or setting at liberty a person arrested or imprisoned for any action, either civil or criminal, on surety taken for his appearance at a certain place and on a particular day. And the object of bail is to satisfy the condemnation and costs in the action, or render the defendant to prison. In criminal cases, every defendant is not bailable, as for treason, murder, manslaughter, &c.

**BALANCE**, in Mechanics, a peculiar application of the lever, in order to determine the difference or equality of weights in heavy bodies, and consequently their masses or quantity of matter. There are various kinds of balances; the principal of which, however, are the Common balance, the Bent Lever balance, the Roman balance, and the Swedish or Danish balance. Balances also receive other denominations, according to the circumstances under which they are employed, or the principles on which they act, as Assay balance, Hydrostatic balance, &c.

*The Common BALANCE, or Scale.* This instrument is too well-known to need any particular description; it consists of a lever A C, with equal arms, at the extremity of each of which is attached a scale, as D and E, and, before loading it with any weights, the whole ought to preserve a perfect equilibrium; and this equilibrium must arise from an exact distribution of the weight of each arm and scale of the balance, as well as from the equal length of the former; for on this depends the accuracy of its action. The following obser-

ations have been made, with regard to the accuracy of the balance:—"It should rest in a horizontal position when loaded with equal weights. It should have great sensibility; that is, the addition of a small weight in either scale should disturb the equilibrium, and make the beam incline sensibly from the horizontal position. It should have great stability; that is, when disturbed, it should quickly return to a state of rest. That the first requisite may be obtained, the beam must have equal arms, and the centre of suspension must be higher than the centre of gravity. Were these centres to coincide, the beam, when the weights were equal, would rest in any position, and the addition of the smallest weight would overset the

# BALANCES.

*Hydrostatic Balance.*

*Roman Balance.*

Fig. 6.

Fig. 5.

*Bentlever Balance.*

balance, and place the beam in a vertical situation, from which it would have no tendency to return. The sensibility, in this case, would be the greatest possible; but the other two requisites, of level and stability, would be entirely lost. The case would be even worse, if the centre of gravity were lower than the centre of suspension, as the balance, when deranged, would make a revolution of no less than a semicircle. When the centre of suspension is higher than the centre of gravity, if the weights be equal, the beam will be horizontal; and if they be unequal, it will take an oblique position, and will raise the centre of gravity of the whole, making the momentum on the side of the lighter weight equal to that on the side of the heavier, so that an equilibrium will again take place. The second requisite is the sensibility of the balance, or the smallness of the weight by which a given angle of inclination is produced. If  $a$  be the length of the arm of the balance, and  $b$  the distance between the centre of suspension and the centre of gravity,  $P$  the load in either scale, and  $W$  the weight of the beam, the

sensibility of the balance is as  $\frac{a}{b(2P + W)}$ ; it is therefore

greater, the greater the length of the arm, the less the distance between the two centres, and the less the weight with which the balance is loaded. Lastly, The stability, or the force with which the state of equilibrium is recovered, is proportional to  $(2P + W)b$ , the denominator of the preceding fraction. The diminution of  $b$ , therefore, while it increases the sensibility, lessens the stability of the balance. The lengthening of  $a$  will, however, increase the former of these quantities, without diminishing the latter. The above formulæ are of great practical utility, because by means of them, one balance may be made, having exactly the same sensibility and stability with another; it is only required that the ratio of the lengths of the arms should be the same with that which is compounded of the ratios of the distances of the centres of gravity and suspension, and of the weights of the beams.—A balance made by Ramsden for the Royal Society, is capable of weighing ten pounds, and turns with half a grain, or a millionth part of the weight. The descriptions of balances, given by mechanical writers, are generally defective, as they do not give the values of  $a$ ,  $b$ , and  $W$ , the quantities on which the merit of the balance depends, and by the knowledge of which, similar instruments might be constructed. In some of the nicest balances,  $b$  is made variable by means of a small moveable weight."

**Compound BALANCE**, is a combination of several balances employed in weighing very heavy bodies, as anchors, great guns, &c.

**Bent Lever BALANCE**. See Plate, *Balances*, fig. 1. This instrument operates by a fixed weight  $C$  at the end of the bent lever  $ABC$ , supported on its axis  $B$ , in the pillar  $IH$ , having a scale  $E$  suspended from the other extremity of the lever at  $A$ . Draw the horizontal line  $KBG$  through  $B$ , the centre of motion, on which from  $A$  and  $C$  let fall the perpendiculars  $AK$ ,  $CD$ ; then if  $BK$  and  $BD$  are reciprocally in proportion to the weights at  $A$  and  $C$ , they will be in equilibrio; but if not, the weight  $C$  will move upwards or downwards along the arc  $FG$ , till that ratio be obtained. If the lever be so bent, that when  $A$  coincides with the line  $GK$ ,  $C$  coincides with the vertical  $BH$ , then as  $C$  moves from  $F$  to  $G$ , its momentum will increase, while that of the weight in the scale  $E$  will decrease; hence the weights in  $E$  corresponding to different positions of the balance, may be expressed on the graduated arc  $FG$ , and the whole used in the same way as the steel-yard.

**Hydrostatic BALANCE**, (Plate, fig. 2,) an instrument used for determining the specific gravity of bodies, whether fluid or solid: there are various constructions given to this instrument, but the following appears to be of all others the most accurate.  $VCG$ , is the stand or pillar of this hydrostatic balance, which is to be fixed in a table. From the top  $A$  hangs, by two silk strings, the horizontal bar  $BB$ , from which is suspended, by a ring  $i$ , the fine beam of a balance  $b$ ; which is prevented from descending too low on either side by the gently springing piece  $xyz$ , fixed on the support  $M$ . The harness is annulated at  $o$ , to shew distinctly the perpendicular position

of the examen, by the small pointed index fixed above it. The strings by which the balance is suspended, passing over two pulleys, one on each side the piece at  $A$ , go down to the bottom on the other side, and are hung over the hook at  $v$ ; which hook, by means of a screw  $P$ , is moveable about one inch and a quarter, backward and forward, and therefore the balance may be raised or depressed so much. But if a greater elevation or depression be required, the sliding piece  $S$ , which carries the screw  $P$ , is readily moved to any part of the square brass rod  $VK$ , and fixed by means of a screw. The motion of the balance being thus adjusted, the rest of the apparatus is as follows:— $HH$  is a small board, fixed upon the piece  $D$ , under the scales  $d$  and  $e$ , and is moveable up and down in a low slit in the pillar above  $C$ , and fastened at any part by a screw behind. From the point in the middle of the bottom of each scale, hang, by a fine hook, brass wires  $ad$  and  $ac$ . These pass through two holes  $m$ ,  $m$  in the table. To the wire  $ad$  is suspended a curious cylindric wire  $rs$ , perforated at each end for that purpose: this wire  $rs$  is covered with paper, graduated by equal divisions, and is about five inches long. In the corner of the board at  $E$  is fixed a brass tube, on which a round wire  $hl$  is so adapted as to move neither too tight nor too free, by its flat head  $l$ . Upon the lower part of this moves another tube  $Q$ , which has sufficient friction to make it remain in any position required: to this is fixed an index  $T$ , moving horizontally when the wire  $hl$  is turned about, and therefore may be easily set to the graduated wire  $rs$ . To the lower end of the wire  $rs$  hangs a weight  $L$ ; and to that a wire  $pn$ , with a small brass ball  $g$ , about one-fourth of an inch diameter. On the other side, to the wire  $ac$ , hangs a large glass bubble  $B'$  by a horse-hair. Let us first suppose the weight  $L$  taken away, and the wire  $pn$  suspended from  $S$ , and, on the other side, let the bubble  $B'$  be taken away, and the weight  $F$ , suspended at  $c$ , in its room. This weight  $F$  we suppose to be sufficient to keep the several parts hanging to the other scale in equilibrio; at the same time that the middle point of the wire  $pn$  is at the surface of the water in the vessel  $O$ . The wire  $pn$  is to be of such a size, that the length of one inch shall weigh four grains. Now it is evident, since brass is eight times heavier than water, that for every inch the wire sinks in the water, it will become half a grain lighter and half a grain heavier for every inch it rises out of the water: consequently, by sinking two inches below the middle point, or rising two inches above it, the wire will become one grain lighter or heavier. Therefore, if when the middle point is at the surface of the water in equilibrio, the index  $T$  be set to the middle point  $a'$  of the graduated wire  $rs$ , and the distance on each side  $a'r$  and  $a's$  contains 100 equal parts; then, if in weighing bodies the weight is required to the hundredth part of a grain, it may be easily had by proceeding in the following manner. Let the body to be weighed be placed in the scale  $d$ . Put a weight into the scale  $e$ ; and let this be so determined, that one grain more shall be too much, and one grain less too little. Then the balance being moved gently up or down, by the screw  $P$ , till the equilibrium be nicely shewn at  $o$ ; if the index  $T$  be at the middle point  $a'$  of the wire  $rs$ , it shews that the weights put into the scale  $e$  are just equal to the weight of the body. By this method we find the absolute weight of the body: the relative weight is found by weighing it hydrostatically in water, as follows:—Instead of putting the body in the scale  $e$ , as before, let it hang with the weight  $F$ , at the hook  $c$ , by a horse-hair, as at  $B$ , supposing the vessel  $N$  of water were away. The equilibrium being then made, the index  $T$  standing between  $a'$  and  $r$ , at the 36th division, shews the weight of the body put in to be 1095, 36 grains. As it thus hangs, let it be immersed in the water of the vessel  $N$ , and it will become much lighter: the scale  $e$  will descend till the beam of the balance rests on the support  $z$ . Then suppose 100 grains put into the scale  $d$  restore the equilibrium precisely, so that the index  $T$  stand at the 36th division above  $a'$ ; it is evident that the weight of an equal bulk of water would, in this case, be exactly 100 grains. After a like manner, this balance may be applied to find the specific gravity of liquids, as is easy to conceive from what has been already said. The weight of a cylinder, of the fluid whose base is  $EF$  and altitude  $AG$ , will disturb the equilibrium. See GRAVITY, *Specific*.

**Roman BALANCE, or Steel-Yard, (Plate, fig. 3.)** A B represents an instrument of this kind: *a* the trutina, or handle, on which the beam turns; *k* a ring on which the balance may be suspended on a nail or hook; *f* the hook on which the substance to be weighed, is hung; *c* a collar or guard, by which the hook is fastened to the beam; *h* a swivel; *i* the counterpoise. If now the body to be weighed be fastened to the hook *f*, and the whole suspended by the ring *k*, the division on which the counterpoise is placed to maintain an equilibrium in the balance, will shew the weight of the body required; the weight of the counterpoise *i* being known, and the large divisions 1, 2, 3, &c. equal to the distance between the centre of the balance and the screw which fastens the guard *C* to the shorter arm of the balance. When the body to be weighed is heavier than the divisions on the longer arm will indicate, the balance is turned the lower side upwards, and suspended on the other ring *b*, by which means the divisions become shorter, because the distance between the trutina *d*, and the screw on which the guard *e* moves, is less: the divisions on this side of the figure extending to 17, whereas they only extend to six on the other. The steelyard itself, and its whole apparatus, should be in equilibrium when suspended on the ring *k* or *b*.

The **Danish BALANCE**, is a kind of steelyard in common use in many parts of Europe, and is of very simple construction, consisting of a batten of hard wood, having a heavy lump *K*, as in the annexed figure, at one end, and a swivel hook *b* at the other.

The goods to be weighed are suspended on the hook, and the whole is carried in a loop of whipcord *F*, in which it is slid backward and forward till the goods are balanced by the weight of the other end. The weight of the goods is estimated by the loop on a scale of divisions, effected by a method purely geometrical:—Let *AC* (figures 1 and 2,) be the distance between the point *A*, from which the body whose weight is to be determined is suspended, and *C* the centre of gravity of the balance when the weight *W* is not attached to it.

From the point *C* draw an indefinite line *CD*, making an angle *ACD* with the line *AC* on which the divisions of the balance are to be marked, and through *A* draw another right line *AN* parallel to *CD*. Set off any equal distances *CE*, *EF*, *FG*, *GH*, *HI*, &c. along the line *CD*; and upon *AN*, set off the distance *AB* equal to one of the equal distances, as *CE*, upon *CD*. From *B* as a fixed point draw lines *BE*, *BF*, *BG*, *BH*, &c. to the several points of division on *CD*; and they will intersect the line *AC*, in the points 1, 2, 3, 4, 5, &c. where the subdivision marks ought to stand in the balance, figure 1. The numbers 1, 2, 3, 4, &c. fig. 2, denote so many times the actual weight of the balance and its knobs, independent of the adventitious weight *W*. Thus if the unloaded balance weigh 6 lbs, the distances marked 1, 2, 3, 4, 5, &c. in fig. 2, would correspond to the subdivision marks 6, 12, 18, 24, 30, &c. in fig. 1. The truth of this construction may be easily shewn thus: Let *w* be the weight of the balance and knob, and *W* that of the body which is to be ascertained by the instrument. Then, when the point of suspension is that marked 1, fig. 2, we have in the triangles *AB1*, *1CE*, the sides *AB* and *CE* equal, also angle *BA1* = *1CE*, and *B1A* = *E1C*; therefore these triangles are both equiangular and equilateral; consequently, *A1* = *1C*, and, by the nature of the lever, and the centre of gravity, *W* = *w*. Again, in like manner when the point of suspension is 2, the triangles *AB2*, *2CF*, are equiangular; and since *FC* = *2AB*, we have *C2* = *2A2*, and *W* = *2w*. So also the triangles *AB3*, *3CG*, are equiangular; whence be-

cause *CG* = *3AB*, *C3* = *3A3*, and *W* = *3w*, and so on, through the whole division.

This balance (says Dr. Gregory,) has been described more on account of its curiosity than actual utility; for in ascertaining large weights it would be extremely cumbersome and difficult to manage. In the determination of weights not exceeding twenty or thirty pounds, it might, however, be rendered very manageable; for it might be about the length of an exciseman's rod, or a walking stick, having a knob of lead at one end; and in this case the divisions near the knob might be so numerous as to enable a person to weigh accurately to quarters of pounds, if not to ounces: the rod might be moved to and fro upon a chair-back, or the edge of a trussel; and thus this instrument might often be more conveniently used than a spring steelyard.

**Fidler's BALANCE**, as here represented, was made for the Royal Institution, and does not differ much from those constructed by Ramsden and Troughton.

The middle column *A* can be raised at pleasure by the nut *B*, and supports the round ends of the axis in the forks at its upper extremity, in order to remove the pressure on the sharp edges of the axis within the forks. *C* and *D* are pillars which occasionally support the scales, and may be elevated or depressed, by turning the nut *E*. The screw *F* raises or depresses a weight within the conical beam, for the purpose of regulating the position of the centre of gravity; and the graduated arc *G* measures the extent of the vibrations.

An *Improvement on this Balance*, is represented below, where *DC* is a micrometer screw, fixed to the arm *FA*, so

that when it is turned round by the nut *D*, it neither approaches to nor recedes from the centre of motion *F*. The screw *DC* works in a female screw, in the small weight *n*, and by revolving in one direction carries this weight from *S* to *R*, and thus gives the preponderance to the scale *G*. The recession of the weight *n* from the centre *F* is measured, as in the common micrometer; and a weight *x* placed in the scale suspended at *A*, will be in equilibrio with *n*, placed at any distance *Sn*,

$$\text{when } x = \frac{Sn \times n}{FA}.$$

**Proney's BALANCE Support, (Plate, fig. 4.)** for balances of all dimensions, is calculated to render the operations for which these instruments are used more expeditious and convenient, without diminishing their accuracy.

"Several experiments," says he, "in which I was engaged during the course of the last winter, put me under the necessity of contriving a support which might be applied promiscuously to every kind of balance, whether provided with a suspending handle or not, and which, without detriment to its accuracy, should afford me commodious means of successively raising and lowering it. It is well known how embarrassing and laborious the operation of weighing is, when performed with balances supported by the hand; though this is often only the smallest inconvenience with which their use is attended.

"Various artists have contrived supports, commodious in

their use, and ingenious in their principle; but as each of these supports can only be adapted to a single balance, they become so expensive as to be out of the reach of the majority of artists and experimentalists. I think, therefore, I shall do them an acceptable service by publishing, in compliance with the request of several eminent chemists, the description of a support, which, besides the advantage of being adapted for all kinds of balances, possesses that of being constructed at a small expense, either in wood or metal.

"A triangular foot of brass *Aa, a, a*, (figs. 4, 5, representing the elevation and section of my apparatus,) has its three extremities *a, a, a*, firmly screwed down upon a table or horizontal plane. Into the part *A* of this foot is screwed a cylindrical rod, *AB*, which may be of any arbitrary length: it may even be convenient to have two of these of different lengths, in order that they may be changed, when we wish to employ the machine for very large balances. Those which I have made use of are, the one half a metre, and the other one metre (39·4 inches) in length.

"A vertical pulley, *P*, is placed at the top of the stem *AB*, in such a manner that the same vertical plane passes through the axis of the rod, and through the horizontal axis of the pulley; the block or collar *CD* of this pulley has at its lower part a tube *CB*, into which enters, with a gentle friction, the superior extremity of the rod *AB*; a screw, *E*, serves to keep the pulley in a fixed position.

"Another pulley, *P*, fig. 5, is fixed at the bottom of the rod *AB*, in such a position that the tangent or cord of the pulleys *P* and *P* is parallel to the axis of the rod *AB*.

"A cord *KtpHGPF*, to the end of which is suspended on the outside of the vertical table *K* a small weight *h*, passes through a hole *t* made in the foot *a*, rolls over the pulleys *p* and *P*, and is attached at *F* to a piece *m m' nq*, which has the form of a fork, and to which are suspended (as I shall shortly explain) the balance, the weights, and the substances that are to be weighed. *Fm* is a button, which being screwed at the top of the fork, receives the end of the cord, and by means of a knot made on it sustains the fork.

"The tail or handle of this fork is of a prismatic form at the part *m' n*; this prismatic part enters a groove *ff* made at the extremity *N* of the horizontal piece *NO*, so that it can slide freely in this groove either upwards or downwards, its course being, however, limited at *m'*, where it is stopped by the enlarged handle of the fork, and at *n* by the greater width produced by the separation of the two branches of the fork.

"The piece *NO*, which is hollow, and intersected at *O* by the stem *AB*, can slide along and turn round this stem: when it is brought to its proper height, it is secured by means of the screw *V*, and it is then necessary, first, that it should be at such a height, that, when the stop *m* rests on the side of the groove *ff*, or when *NO* can move no further down, the scale of the balance shall be in contact with the table or horizontal plane, in order that we may afterwards be able to raise it the whole height of *fn*; secondly, that the cord *FF* be in one and the same vertical plane with *HG*.

"The groove at *N* ought to be situated in such a manner that the axis of the prismatic part of the tail of the fork, and the cord *FF*, shall always be in the same vertical plane, or in a parallel line with the axis of the stem *AB*.

"These dispositions being made, let us imagine the two branches *nq* of the fork to be perforated with holes of different diameters, in order to receive horizontal pins (*gg*) of different sizes; and we shall have all that is requisite for the ordinary operations of weighing, performed in the air with balances, the beams of which are suspended from above.

"In fact, whatever kind of balance we use, we are to introduce the extremity of its suspending handle into the fork *nq*, and insert into the round hole, which the handle of the balance always has at its superior extremity, any one of the pins that will enter with ease; we then apply the piece *ON* in such a manner as to fulfil the conditions above laid down for the position of this piece; after which, it is to be fixed by the screw *V*. This being done, the scales of the balance are to be charged, which being in contact with the table, or horizontal plane, can have no motion. When the scales are charged, we lay hold of the small ball *k*, and draw the cord which suspends

it so as to raise the balance very slowly: if the scales be not in equilibrio, the cord is to be loosened till they rest again upon the table, and so successively.

"A counterpoise, *Q*, suspended to the cord *FG*, ought to preserve the equilibrium with the weight of the balance. By means of this precaution it comes to pass, that the common centre of gravity of all the forces supported by the pulley *P*, falls in all cases upon the axis of the stem *AB*, which thus has no tendency to bend.

"If we wish now to use a hydrostatic balance, we adapt to the stem *AB* a small board *O' N'* which, by means of a

cylindrical hole at *O'*, may slide along the rod *AB*, and be fixed at any arbitrary height by a screw at *V'*. Another piece, or board *K' K'*, is placed upon *V' N'*, in such a manner that the holes *TT* correspond with the centre of the scales, under which are placed the hooks intended for holding the substances suspended in the water, and *K' K'* is fixed upon *V' N* by means of screws *V'*.

"These arrangements being made, let the piece *N' O'* and the board *K' K'*, be placed in such a manner that, first, the whole height of the balance be placed between this piece and the board, and that scales *LL* be in contact with the board *K' K'*, their centres corresponding with holes made in *TT*. Secondly, that *K' K'* be sufficiently elevated to enable us to place under it the vessels *WW*, filled with water, and conveniently to immerse, in one of these vessels, the substances which we wish to weigh hydrostatically.

"According to the common practice, these substances are suspended by a very thin wire; but by placing, after my method, two vessels, and suspending to the two scales wires of equal diameter, the one of which supports the substance that is to be weighed, and the other merely in part immersed, the magnitude of the diameter will have no influence upon the accuracy of the operation; for, let us suppose the apparatus to be adjusted in such a manner that at first the two wires were in equilibrio with each other, (which may easily be obtained by varying the height of the water in the vessels,) these two wires will still be in equilibrio, when the beam *F F'* being elevated, will remain in its horizontal position: whence it follows, that if one of the wires have suspended from it a substance immersed in the water, and we place in the opposite scale, and consequently out of the water, a weight adequate to keep the equilibrium with the immersed substance, for a horizontal position of the beam, the equilibrium will still be maintained, whatever may be the elevation or depression of the beam, provided it continue in a horizontal position; for the lengths of the wires, either above or below the surface of the water, being equal, the difference between the specific weight of the water and that of the metal will operate equally upon both extremities of the beam. It is evident that this advantage will not be obtained if we employ only the wire to which the substance is suspended, and that the equilibrium, established for a certain elevation and a horizontal position of the beam, will not apply to other elevations of the beam by preserving it in the horizontal position.

"It is to be remarked, that my method compensates not only for the excess of the specific weight of the wires over that of the water, but also for that which depends upon the adhesion of the fluid to the wires, and the covering of water which they carry along with them.

"All that has been said hitherto applies only to balances that are provided with suspended handles; but, in order to render this support absolutely universal in its use, it was necessary that it should be possible to adapt it to a beam which had nothing but its centres; for which purpose I contrived an apparatus, which is suspended, like those of a common balance, to the fork *nq*, and which may receive the centres of any beam. The engravings in the plate represent it provided with this apparatus, the construction of which is as follows.

"A piece *ss'* fig. 6, has a screwed hole bored into it at *s'*, into which the screw *dd* is inserted half its length. Another hole, made at *s*, in a perpendicular direction to the first, receives the pin *gg*, to which all the inferior apparatus is suspended. This hole *s* supplies the place of that which is found at the upper extremity of the suspending handle of balances.

"The two other vertical pieces *r, r*, (fig. 6 and 7,) have at their upper part cylindrical holes not screwed, in which the screw *dd* can turn freely. These superior parts are placed at an arbitrary distance, and retained in their situation by means of four nut-screws *u, u, u, u*, each of the pieces being fastened between two of these nut-screws. A cylindrical rod *hh* traverses the inferior parts of these pieces *r, r*, and is fixed there by means of nut-screws, in such a manner that the superior and inferior points of the piece *rr* are invariably at the same distance.

"Each of these pieces *r, r* has, upon the surface which is perpendicular to the direction of *dd* and *hh*, a groove *ee*, and a circular aperture *X*, having at its lower part a small bracket of polished steel *aa*, intended to support one of the centres of the beam. Into the upper part of the grooves *ee* a rule *e'e'* is introduced, which must enter with tightness, and which, with the pieces *dd* and *hh*, give such a solidity to the apparatus, that the adjustment of its parts cannot be in the smallest degree deranged. The remainder of the groove which is not occupied by *e'e'*, ought to be of a length somewhat greater than that of the largest cock or index adapted to the beams which we shall have to use.

"The method of using the apparatus which I have just described is very simple. The beam which we intend to employ is placed between the two branches *r, r*, which are removed from each other till the centres can be brought opposite to the circular holes *X*; the pieces *r, r* are then brought together in such a manner that the centres enter these holes *X*, and so as still to leave some room for motion between these pieces and the body of the beam, in order that the oscillations of the balance may be perfectly free. The pieces *r, r*, are brought parallel with each other, and the adjustment of the apparatus is rendered perfectly firm, by means of nut-screws, by the small cylindrical rod *hh*, and by the rule *e'e'*. The apparatus being adjusted in this manner, it is suspended to the fork *ng*, by inserting the pin *gg* into the hole *s*, and the balance is used in the manner that has already been explained. We know the equilibrium to be established, and the beam to be horizontal, when the index *yy* divides the breadth of the space *ee* into two equal parts; but, in order to ascertain the circumstances with greater accuracy, I have attached to the rule *e'e'* a plummet *e'i*, by means of which we may distinguish the slightest deviations of the index from the perpendicular direction."

**BALANCE** of a *Clock*, or *Watch*, is that part which by its motion regulates and determines the beats. The circular part of it is called the *rim*, and its spindle the *verge*; there belong to it also two pallets or nuts, that play in the fangs of the crown-wheel: in pocket watches, that strong stud in which the lower pivot of the verge plays, and in the middle of which one pivot of the crown-wheel runs, is called the *potence*: the wrought piece which covers the balance, and in which the upper pivot of the balance plays, is the *cock*; and the small spring in the new pocket watches is called the *regulator*.

The motion of a balance, as well as that of a pendulum, being reciprocating, while the pressure of the wheels is constantly in one direction, it is obvious that some art must be used to accommodate the one to the other. When a tooth of the wheel has given the balance a motion in one direction, it must quit it, that it may get an impulsion in the opposite direction. The balance or pendulum thus escaping from the tooth of the wheel, or the tooth escaping from the balance, has given to the general construction the name of *scapement* among our artists. See **SCAPEMENT**.

Dr. Gregory observes, that some of the most important propositions relative to watch balances may be concisely stated as follows: 1. The balance of a watch is analogous to the pendulum in its properties and use. The simple balance is a circular annulus, equally heavy in all its parts, and concentric with the pivots of the axis on which it is mounted. This

balance is moved by a spiral spring called the balance spring, the invention of Mr. Hook.

2. The pendulum requires a less maintaining power than the balance. Hence the natural isochronism of the pendulum is less disturbed by the relatively small inequalities of the maintaining power.

3. The elastic force of the spring which impels the circumference of the balance is directly as the tension of the spring; that is, the weights necessary to counterpoise a spiral spring's elastic force, when the balance is wound to different distances from the quiescent point, are in the direct ratio of the arcs through which it is wound.

4. The vibrations of a balance, whether through great or small arcs, are performed in the same time. For the accelerating force is directly as the distance from the point of quiescence: hence, therefore, the motion of the balance is analogous to that of a pendulum vibrating in cycloidal arches.

5. The time of the vibration of a balance is the same as if a quantity of matter, whose inertia is equal to that by which the mass contained in the balance opposes the communication of motion to the circumference, described a cycloid whose length is equal to the arc of vibration, described by the circumference, the accelerating force being equal to that of the balance.

6. The times of vibration of different balances are in a ratio compounded of the direct subduplicate ratios of their weights and semidiameters, and the inverse subduplicate ratio of the tensions of the springs, or of the weights which counterpoise them, when wound through a given angle.

7. The times of vibration of different balances are in a ratio compounded of the direct simple ratio of the radii and direct subduplicate ratio of their weights, and the inverse subduplicate ratio of the absolute forces of the springs at a given tension.

8. Hence the absolute force of the balance spring, the diameter and weight of the balance being the same, is inversely as the square of the time of one vibration.

9. The absolute force or strength of the balance spring, the time of one vibration, and the weight of the balance, being the same, is inversely as the square of the diameter.

10. The weight of the balance, the strength of the spring, and time of vibration, being the same, is inversely as the square of the diameter.—Hence, a large balance, vibrating in the same time with the same spring, will be much lighter than a small one.

11. If the rim of the balance be always of the same breadth and thickness, so that the weight shall be as the radius, the strength of the spring must be as the cube of the diameter of the balance, that the time of vibration may continue the same.

12. The momentum of the balance is increased better by increasing its diameter than its weight.

13. The longer a detached balance continues its motion, the better.

14. The greater the number of vibrations performed by a balance in a given time, the less susceptible is it of external agitations.

15. Slow vibrations are, to a certain extent, preferable to quick vibrations: but there is manifestly a limit; for if the vibrations be too slow, the watch will be liable to stop.

16. A balance should describe as large arches as possible, as suppose 240°, 260°, 300°, or an entire circle.—First, because the momentum of the balance is thus increased; and therefore the inequalities in the force of maintaining power bear a less proportion to it, and of consequence will have less influence. 2dly. The balance is less susceptible of external agitations. 3dly. A given variation in the extent of the vibrations produces a less variation in the going of the machine. But care must be taken that in these great vibrations, the spring shall neither touch any obstacle, nor its spires touch each other in contracting.

17. The time of the vibration of the balance is increased by heat, and diminished by cold.—First, because the length of the spiral spring is increased by heat, and therefore its force diminished; and the contrary by cold. 2dly. The diameter of the balance is increased by heat, and therefore also the time of vibration; and the contrary by cold.

18. That balance is the most perfect, which, without the compensation of a thermometer, is most subject to the influence of heat and cold. Because the obstructions from oil and friction act as a compensation to the expansion or contraction of the

spring and balance; therefore that balance which is most affected is most free from the influence of oil and friction.

19. The errors in the going of a watch, arising from the change of temperature, may be corrected by varying the length of the balance spring. Nevertheless, as it is extremely difficult to form an isochronal spiral, any variation in its length is dangerous, because we shall thus probably lose that point which determines its isochronism.

20. The errors in the going of a watch, occasioned by the variation of temperature, may be corrected by varying the diameter of the balance.

This may be effected by a peculiar contrivance, which has obtained the name of the *expansion balance*, being composed of two different metals which possess different degrees of expansibility, as brass and steel, for instance; of which two metals it has been observed, that the increase of dimensions by expansion, in like elevations of temperature, is nearly as 2 to 1. For, according to Smeaton's experiments, the corresponding expansions of hard steel and brass wire are as 147 and 232, the expansions being occasioned by a change from a medium temperature to that of 180° of Fahrenheit's thermometer. One of the most approved constructions of an expansion balance, is exhibited in the figure annexed, and is thus generally described: The outer part of the rim is brass, and the inner part steel. After this compound rim is brought to its figure by turning, it is cut through in three places A, B, C, which sets one end of each third part of the periphery at liberty to move outwards when the temperature is diminished, or inwards when it is increased. D, E, F, are three similar and equal masses of metal, fitted upon the circular bars in a proper manner to admit of their being fixed at any required distance from the extremity, where the motion is most considerable. G, H, I, are three screws, the heads of which may be set nearer to, or further from, the centre, and serve as weights to effect the adjustments for position and rate. The peculiar advantage of this balance may be explained as follows: when an increase of heat diminishes the elastic force of the pendulum spring K, the outer brass rim being lengthened more than the steel, must throw the weights D, E, F, nearer to the axis, and diminish the effect of the inertia of the balance, which consequently is as speedily carried through its vibration as before. And, on the contrary, when cold weather adds to the elastic force of the spring, the same weights are also thrown further out, and prevent the acceleration which would have followed. The exact adjustment of the weights is found by trial of the going of the machine: if it gain by heat, the weights do more than compensate, and must be moved further from the extreme ends of the circular compound bars; but if the gain be produced by cold, the spring predominates, and the weights will accordingly require to be set further out.

**BALCONY**, in Architecture, a projection in the front of a house or other building, supported by pillars or consoles, and encompassed with a balustrade or rail.

**BALING OF SHIPS**. An apparatus for this purpose has lately been invented by J. Dennett of Newport, Isle of White, with a view of assisting sailors in baling vessels when the pumps from accident get out of order. We confess we have too high an opinion of Buchanan's pump, the chain pump, and several other hydraulic engines, to fancy the apparatus before us will ever become very general; but such as the invention is, we give it the reader, with the following description:

A and B are parts of the hatchways of the upper and lower decks. CC is a long rebated slide, in an inclined position, reaching from a little above the coamings of the upper deck to the ballast in the hold, and attached to the lower hatchway by a block, D. E is a square bucket, made to slide on the rebate of CC; its bottom is a flap valve, so that when it slides down into the water it opens, the bucket fills instantly, and closes upon being drawn up full of water,

To prevent the bucket from being pulled higher up than is requisite to discharge the water, a knot is worked in the rope which stops the block at L. The block L is made fast to any yardarm, and the upper end of the rope K is secured to the same, or elsewhere, just length enough to let the bucket reach the foot of the slide.

**BALL**, in the Military art, comprehends all sorts of bullets for fire-arms, as cannon balls, which are made of cast-iron; musket bullets, which are cast from lead. See GUNNERY.

**BALL and SOCKET**, an instrument made of brass, with a perpetual screw, or so as to move horizontally, vertically, or obliquely, and is generally used for the managing of surveying or astronomical instruments.

**BALL**, in a popular sense, is any spherical body, whether natural or artificial.

**Fire BALLS**, in Meteorology, are luminous bodies generally appearing at a great height above the earth, and sometimes amazingly vivid and brilliant. See METEOR.

**BALLAST**, a certain portion of stone, iron, gravel, or such like materials, deposited in a ship's hold, when she has either no cargo, or too little to bring her sufficiently low in the water, and is used to counterbalance the effect of the wind upon the masts, and give the ship a proper stability, that she may be enabled to carry sail without danger of overturning. The art of ballasting consists in placing the centre of gravity so as neither to be too high, nor too low, too far forward, nor too far aft, and that the surface of the water may nearly rise to the extreme breadth a-midships, and thus the ship will be enabled to carry a good sail, incline but little, and ply well to windward. *Shingle Ballast*, is ballast of coarse gravel.

**BALLISTA**, a machine used by the ancients for shooting darts; which resembles our crossbow. The annexed figure represents one of these engines used in sieges; 2,2 the base of the ballista; 3,4, upright beams; 5,6, transverse beams; 7,7, the two capitals which cannot be seen in this transverse figure; 9,9, two posts or supports for strengthening the transverse beams; 10,10, two skains of cords fastened to the capitals; 11,11, two arms inserted between the two stands, or parts of the skains; 12, a cord fastened to the two arms; 13, darts which are shot by the ballista; 14,14, curves in the upright beams, and in the concavity of the cushions, are fastened in order to break the force of the arms, which strike against them with great force when the dart 15 is discharged; 16, the arbor of the machine, in which a groove or canal perfectly straight is formed, and in which the darts are placed in order to be shot by the ballista; 17 the nut of the trigger; 19, a hook by which

the chord is drawn towards the centre, and the ballista cocked ; 20, a stage or table, on which the ballista is in part sustained.

Vegetius informs us, that the ballista discharged darts with such rapidity and power, that nothing could resist their force ; and Athenæus adds, that Agistratus made one, of little more than a cubit and a half, which shot darts 500 yards.

**BALISTA**, was formerly also the name given to the cross-staff.

**BALLISTIC PENDULUM**, an ingenious machine, invented by Robins, for ascertaining the velocity of military projectiles, and consequently the force of fired gunpowder. It consists of a large block of wood MN, suspended vertically by a strong horizontal iron axis at S, to which it is connected by a firm iron stem. Now, to determine the velocity with which a ball is projected, the pendulum is so situated that the ball impinges directly against it, and causes it to vibrate through a certain arc, which being accurately observed, the velocity of projection is thence computed. Dr. Hutton made many experiments of this kind, by discharging cannon-balls at various distances from the pendulum ; from which is deduced a complete series of the resistances of the air to balls passing through it, with all degrees of velocities from 0 to 2000 feet per second.

**BALLOON, AIR.** See AEROSTATION.

*Le Ballon Aerostatique*, the Air Balloon, was placed among the constellations by M. de Lalande, a few years back. It is immediately south of the Zodiacal Goat, west of the Southern Fish, north of Microscopium, and east of Sagittarius.

**BALLOTADE**, in the Manage, the leap of a horse between two pillars, or upon a straight line, made with justness of time, with the aid of the hand and the calves of the leg, so that when his forefeet are in the air, he shews nothing but the shoes of his hind feet without jerking out.

**BALLUSTRADE**, a series or row of ballusters, joined by a rail, serving as well for a rest to the elbows, as for a fence or enclosure to balconies, staircases, altars, &c.

**BALM**, a well-known plant, that thrives well in light rich soil, and increases freely by dividing the root. It grows well under the shade of trees, and is a handsome ornament to every flower-garden or cottage. In a fresh state, balm smells something like a lemon, and has a weak rough aromatic taste. On distilling the herb with water, it impregnates the first runnings pretty strongly with its grateful flavour. Prepared as tea, it makes a grateful diluent drink in fevers ; and in this way it is commonly used, either by itself, or tempered with lemon juice.

*The Balsam of Tolu*, from a region on the north coast of South America near the isthmus of Panama, is a resinous fluid, obtained from a tree of the same name by incisions in the trunk, and is useful in medicine both as a tincture and a syrup ; it has an agreeable flavour resembling balm, and, made into lozenges, appeases the irritation occasioned by severe coughing.

**BAMBOO**, a plant, which sometimes grows forty feet high. Its young shoots and roots make an Indian pickle ; its light graceful knotted stalk serves, not only in the East for the construction of houses, but for furnishing them with almost every utensil. Tables, chairs, bedsteads, bedding, barrows, fences, sacking, cordage, oakum, candle-wicks, paper, whips, &c. are

made from bamboo in China. In Malabar, the bamboos are trained over iron arches, and when they have assumed the curve of the mould, are used for roofs to palanquins, and sell at five or six hundred rupees a set. Might not thousands of cottagers in our own country make money by training the willow, the ash, the hazel, and many other trees and shrubs, into similar arches, for innumerable purposes in common life ?

*The Chinese BAMBOO HABIT*, to save shipwrecked persons from drowning, consists of four pieces of bamboo, about a man's length, placed horizontally and at right angles, in parallel pairs, and tied firmly at the four corners ; the opening being

just sufficient to allow the head and shoulders to get through, as represented in the figure, and then tied securely to the body of the person using it. Deal will make this habit equally well.

**BANANA**, a valuable West India plant, whose leaves are six feet long and one foot broad, and the fruit about five inches long, and in shape resembling a cucumber, with a soft luscious pulp, is frequently introduced in desserts, or formed into small loaves, by squeezing out the juice, and leaving it to dry.

**BANGLE EARS**, an imperfection in a horse, remedied by placing his ears in such a manner as you would have them stand : Bind them with two little boards so fast that they cannot stir, and then clip away all the empty wrinkled skin close by the head.

**BANGUE**, a species of opiate, in great use throughout the East for drowning care and inspiring joy, is extracted from the leaf of a kind of wild hemp, that grows in the countries of the Levant. The leaves are dried in the shade, ground to powder, and made into pills or conserves, or taken as a powder. The Turks take this deleterious drug and opium as substitutes for wine, which is forbidden by the Koran to all true Mussulmans.

**BANIAN TREE**, the arched Indian Fig, or God Tree, so named, perhaps, because the Hindoos plant it near their temples, or where no temple exists : the tree itself is made use of

for that purpose. The branches of this famous tree descend, take root, and in time are converted into great trunks, so that a whole tree, with all its props, may cover a space of 2000 feet in circumference.

**BANN**, proscription or banishment for a crime proved; hence, to put a prince under the *bann* of the empire, is, by sound of trumpet, to declare him divested of all his dignities.—*Episcopal BANN* is a fine paid to the bishop by those guilty of sacrilege, or other crimes.—*The Papal BANN* is excommunication.—In Military affairs, a proclamation by beat of drum or sound of trumpet.

**BANQUET**, in Fortification, a platform or bank of earth, upon which soldiers stand within the parapet, to fire upon an enemy in the ditch or covert way.

**BARBACAN**, or **BARBICAN**, an outer defence or fortification to a city or castle, especially a fence to the city or walls. See **CASTLE**. A fort at the entrance to a bridge, &c.

**BARBE**, in Military Tactics, means to fire the cannon over the parapet, instead of firing through the embrasures or port-holes.

**BARBLES**, or **BARBS**, knots of superfluous flesh growing inside the mouths of cattle, and which are cut or burned off, to enable the animals to eat their food.

**BARILLA**, is the Spanish name of a plant, from the burnt ashes of which is produced a salt called *kali* or *soda*, hard solid masses of a bluish tinge, very heavy, sonorous, dry to the touch, corrosive to the taste, and strongly saline, employed chiefly in the manufacture of glass and soap.

**BARK**, in Botany, the skin or covering of plants, shrubs, and trees: as oak bark, which is used in tanning; Jesuit's bark, (*cinchona*), in physic; as also mace, alder, and walnut tree bark, in dyeing; other barks are used in spiceries, as cinnamon, *cassia lignea*. Cork bark is a valuable and useful product. In India and the South Sea islands, cloth is fabricated from the bark of trees.

**BARK STOVE**, or *Moist Stove*, is a hothouse containing a pit or mass of bark, earth, sand, or other matter, in which the pots containing the plants are plunged, or the plants themselves planted. This house is heated from below, or by the fermentation of the bed of materials, as well as by the atmosphere of the house; and it is used solely for raising and cultivating flowers. The bark-stove floriculture house at Frogmore is truly magnificent. Such houses should be built east and west, though those of the botanic gardens of Dublin and Liverpool are placed with their gables to the south. Loddige's immense palmhouse at Hackney is glazed on all sides.

**BARLEY**, a well-known grain or corn, used for making malt, meal, bread, or soups; and sugar boiled in barley water is barley sugar, which is rolled on a stone anointed with oil of sweet almonds, and formed into twisted sticks. Whiskey, made of malt, is distilled by a very common chemical process. The malt is dried, mashed, boiled, and from the liquor thus made, the alcohol, or pure spirit, is distilled. Proof spirit consists of half water and half pure spirit; that is, such as when poured on gunpowder, and set on fire, will burn all away, and permit the powder to take fire and flash, as in open air. But if the spirit be not so highly rectified, there will remain some water, which will make the powder wet, and unfit to take fire. Proof spirit of any kind weighs seven pounds twelve ounces per gallon.

**BARM**, Yeast, first used by the Celtes in making bread. See **BREAD**.

**BAROMETER**, an instrument to measure the elasticity of air, consists of a hollow glass cone, filled with mercury, and hermetically sealed at the end, so that no air be left in it, as represented in the following figure. When it is set upright, the mercury descends down the tube, into the bubble, which has a little opening at the top, that the air may have free ingress and egress. At the top of the tube there must be a perfect vacuum. The instrument is fixed in a frame, and hung perpendicular against a wall. Near the top, on the frame, is placed a scale of inches, shewing how high the mercury is in the tube, above the level of it in the bubble, which is generally from 28 to 31 inches, but mostly about 29 or 30. Along with the scale of inches, there is also placed a scale of such weather as has been observed to answer the several heights of the quicksilver. In dividing the scale of inches, care must be taken to make proper allowance for the rising or falling of the quicksilver in the bubble, which ought to be about half full when it stands at 29½, which is the mean height; for, whilst

the quicksilver rises an inch, it descends a little in the bubble; and that descent must be deducted, which makes the divisions be something less than an inch. These inches must be divided into tenth parts, for the more exact measuring the weight of the atmosphere: for the pillar of mercury in the tube is always equal to the weight of a pillar of the atmosphere of the same thickness; and, as the height of the quicksilver increases or decreases, the weight of the air increases or decreases accordingly. The tube must be near 3 feet long, and the bore not less than ¼ or ⅓ of an inch in diameter, or else the quicksilver will not move freely in it.

The real cause of the suspension of the mercury in the tube, and of water in pumps, is now generally admitted to be the atmospheric pressure, and repeated observations which have been made, connected with this subject, discover that the column of mercury varies considerably in its height, at different times, and this variation has been observed to be followed by changes of the weather. This, in the infancy of meteorological

science, led to farther and more accurate observations, and various alterations and improvements were suggested in the construction of the barometer, or *weather-glass*.

The constructions of this instrument are now exceedingly varied and numerous, much beyond what our limits will admit of enumerating; we must, therefore, content ourselves with describing the most popular and general forms, and refer the reader who wishes for farther information to the article **BAROMETER**, in Rees's Cyclopaedia, where he will find a detailed account of nearly all the forms and uses to which this instrument has been applied.

**Common BAROMETER**.—This is represented in the figure above, such as it was invented by Torricelli. A B is a glass tube open at one end, and hermetically sealed at the other, A, having its diameter about one-third or one-fourth of an inch, and its length thirty-three or thirty-four inches: this is filled with purified mercury so justly as not to have any air over it, nor any bubbles adhering to the sides of the tube, which is best done by means of a small paper or glass funnel, with a capillary tube. The orifice of the tube, filled after this manner, so as to overflow, is then closely pressed by the finger, so as to exclude any air between it and the mercury; this done, invert the tube, and immerse the finger and end, thus stopped, into a bason of like purified quicksilver, and in this position withdraw the finger, and the mercury will descend in the tube to some place, as E, between twenty-eight and thirty-one inches above the surface of the mercury in the bason at F; these being the limits between which it always stands near the surface of the earth or sea. Instead, however, of the detached vessel C D, the modern barometer tubes are curved at the bottom, and terminate in a bulb, which ought to be as big as it can be conveniently made, in order that the variation in the altitude of the mercury in the tube may affect, as little as possible, the depth of that in the bulb.

The barometer tubes, under either of the above forms, are now to be enclosed in a wooden case or frame, to prevent their being broken, and the vessel or bulb, though open to the air, must be secured from dust; and thus far the construction will be completed.

Next, measure from the surface of the mercury at F, 28 inches to G, and 31 inches to H; dividing the spaces between them into inches and tenths, which are marked on a scale placed against the side of the tube; and these tenths are again subdivided into hundredth parts of an inch, by means of a sliding index carrying a *vernier* or *nonius*. In the common barometers called *weather-glasses*, the lowest limit at G is marked *stormy*, and the highest point, H, is marked on one side *very dry* for summer, and on the other, *very hard frost* for winter. To the next half-inch below the highest point are annexed *set fair* on the one side, and *set frost* on the other. At the height of 30 inches, *fair* is marked on one side, and *frost* on the other. At the height of 29½ inches is marked *changeable*, both for summer and winter; and at 29 inches, *rain* on one

side, and snow on the other. At  $28\frac{1}{2}$  inches, *much rain* on one side, and *much snow* on the other; the lowest division being marked *stormy*, as we have before observed.

The barometer is advantageously employed in measuring the heights of mountains; and for every 103 feet perpendicular that the instrument is carried up a mountain, the mercury falls  $\frac{1}{10}$ th of an inch; 103 feet of air being equal to  $\frac{1}{10}$ th of an inch of mercury on the surface of the earth: that is, to one degree in the scale of the barometer. Thus, on the top of Snowden, in Wales, the mercury sinks 3.67 inches, therefore that mountain is 3720 feet high.

A thermometer should always be attached to the barometer, and by the side of it a scale of correction, to shew how much to add or subtract from the height of the mercury in the barometer, for the degree of temperature; for it is evident, that the mercury in the tube will be affected by heat and cold in the same manner as the thermometer, and, on that account, it will not shew the true weight of the atmosphere. For, by numerous experiments it has been found, that air expands about  $\frac{1}{435}$ th part of its bulk for every degree of heat, and contracts the same for every degree of cold, and consequently, the result obtained from the above formula must be increased or diminished by as many times  $\frac{1}{435}$ th part of itself, as the temperature in degrees exceeds, or is less than,  $31^{\circ}$ . Hence we have another rule for measuring altitudes by the barometer, *viz.*

Observe the height of the mercury at the bottom of the object to be measured, and again at its top; as also the degree of the thermometer in both these situations; and half the sum of these two last may be accounted the mean temperature. Then multiply the difference of the logarithms of the two heights of the barometer by 10,000, and correct the result by adding or subtracting so many times its  $\frac{1}{435}$ th part, as the degrees of the mean temperature are more or less than  $31^{\circ}$ ; and the last number will be the altitude in fathoms.

*Example.*—If the heights of the barometer at the bottom and top of a hill are 29.37 and 26.59 inches respectively, and the mean temperature  $26^{\circ}$ , what is the height?

$$\text{Log. } 29.37 = 1.467904$$

$$\text{Log. } 26.59 = 1.424718$$

$$\text{Difference of Logs.} = 0.043186$$

$$\text{Multiply by } 10000$$

$$431.86$$

Now  $31^{\circ} - 26^{\circ} = 5^{\circ}$  temperature below  $31^{\circ}$ ; therefore  $\frac{5}{435}$  of  $431.86 = 4.96$ ; consequently  $431.86 - 4.96 = 426.90$  fathoms, the altitude of the hill.

This requires, however, certain modifications, on account of the difference in low and elevated situations, the expansion of the column of mercury, and other circumstances, which the limits of our article will not admit of investigating. Before M. de Luc began his experiments with the barometer, a mean of the two temperatures shewn by the thermometer attached to the barometer, and the height of the barometer, at the bottom and top of a hill, were thought sufficient for determining its altitude. De Luc, however, found that an additional or detached thermometer was also necessary; and this has been since confirmed by the experiments of General Roy and Sir G. Shuckburgh. The formulæ for the height in fathoms, according to the two latter observers, are as follow:

ROY.

$$\{10000 l = .468 d\} \times \{1 + (f - 32^{\circ}) .00245\}$$

SHUCKBURGH.

$$\{10000 l = .440 d\} \times \{1 + (f - 32^{\circ}) .00243\}$$

Where  $l$  = diff. of logs. of the heights of barometer,  
 $d$  = diff. of degrees Fahrenheit's thermometer,  
 $f$  = mean of the two temperatures shewn by the detached thermometer exposed for a few minutes to the open air in the shade of the two stations.

The sign — takes place when the attached thermometer is highest at the lower station, and the sign + when it is lowest at that station.

*Example.*—Find the height of a mountain, from the following observations taken at the foot and summit:

|                                                                  | Barom. | Attach. Therm. | Detach. Therm.     |
|------------------------------------------------------------------|--------|----------------|--------------------|
| Lowest station, 29.862                                           | .....  | $68^{\circ}$   | ..... $71^{\circ}$ |
| Highest station, 26.137                                          | .....  | $63^{\circ}$   | ..... $55^{\circ}$ |
| Here we have, $d = 5^{\circ}$ , difference detached thermometer. |        |                |                    |
| And..... $f = 63^{\circ}$ , mean of attached thermometer.        |        |                |                    |
| Log. 29.862 = 1.475119                                           |        |                |                    |
| Log. 26.137 = 1.417256                                           |        |                |                    |

$$\text{Difference of Logs.} = 0.057863 = l.$$

Then, by the first formula,

$$f - 32^{\circ} = 31^{\circ}, \text{ and } 1 + (31 \times .00245) = 1.07595$$

$$10000 l = 10000 \times .057863 = 578.63$$

$$.468 d = .468 \times 5 = 2.34$$

$$576.29$$

$$\text{Multiply by } 1.07595$$

$$620 \text{ fathoms,}$$

the altitude sought; the decimals being rejected as unimportant.

Ramsden's engraved table gives the height = 3730 feet, or 621 $\frac{1}{2}$  fathoms. This table is on a slip of paper, a foot long and about  $3\frac{1}{4}$  inches wide; the logarithmic differences, from 25 to 31 inches, are given to 500ths of an inch, and the corrections for the thermometer at both stations found by inspection.

It may be observed, that in determining altitudes by the barometer, it is best to make the observations at the upper and lower stations at one and the same time, as nearly as can be; but great care must be taken that the two barometers, and also the thermometers, are alike; that is, they should precisely agree when together in all states of the air. It is also necessary that the specific gravity of the mercury be well ascertained, because it is not equally pure in all barometers; which is the principal reason why different results have been so frequently obtained, from observations made with different barometers at the same stations. Other circumstances, not generally known, may contribute to such disagreement; thus, Mr. Ramsden proved, by experiment, that the quicksilver in barometer tubes, made of different sorts of glass, will be suspended at different heights.

In the following Table, for measuring the altitude of any mountain, the first column expresses its height in feet or miles; the second, the height of the quicksilver; and the third, the descent of the quicksilver in the barometer; and this at a mean density of the air.

| Feet. | High. Barom. | Descent. | Feet. | High. Barom. | Descent. |
|-------|--------------|----------|-------|--------------|----------|
| 0     | 29.500       |          |       |              |          |

*The Table continued, in Miles.*

| Miles. | High. Barom. | Descent. | Miles. | High. Barom. | Descent. |
|--------|--------------|----------|--------|--------------|----------|
| 0      | 29.50        |          |        |              |          |
| 0.25   | 28.21        | 1.29     | 3.25   | 16.57        | 12.93    |
| 0.50   | 26.98        | 2.52     | 3.50   | 15.85        | 13.65    |
| 0.75   | 25.80        | 3.70     | 3.75   | 15.16        | 14.34    |
| 1      | 24.70        | 4.80     | 4      | 14.50        | 15.00    |
| 1.25   | 23.62        | 5.88     | 4.25   | 13.87        | 15.63    |
| 1.50   | 22.60        | 6.90     | 4.50   | 13.27        | 16.23    |
| 1.75   | 21.62        | 7.88     | 4.75   | 12.70        | 16.80    |
| 2      | 20.68        | 8.82     | 5      | 12.15        | 17.35    |
| 2.25   | 19.78        | 9.72     | 5.25   | 11.62        | 17.88    |
| 2.50   | 18.93        | 10.57    | 5.50   | 11.12        | 18.38    |
| 2.75   | 18.11        | 11.39    | 5.75   | 10.64        | 18.86    |
| 3      | 17.32        | 12.18    | 6      | 10.18        | 19.32    |

Another sort of barometer shews the ascent and descent of the mercury at the bottom, as A B C (annexed figure) a recurve tube, close at the top, where the bucket C is, and open at the end A. The length of C B is 32 or 33 inches, and of A B 6 or 7. The bucket C should contain about as much as the end A B; and the bucket and end C B must be quite filled with mercury, as far as B, a little beyond the turn. The wider the bucket C is, the better. The scale set to the end A B must be graduated downwards; for the mercury falls in this, when it rises in the other sort. This being placed against a wall, will shew the height of the mercury, as in the common ones; and this way is more commodious, as it saves the labour of clambering up upon chairs to see it, as one must do, in the common sort, to see the index exactly.

A barometer may also be made of water, (as in the lower figure,) which is a water-barometer. A B is a glass tube open at both ends, and cemented close in the mouth of the bottle E F, and reaching very near the bottom; then, warming the bottle at the fire, part of the air will fly out; then the end A is put into a vessel of water mixed with cochineal, which will go through the pipe into the bottle as it grows cold. Then it is set upright; and the water may be made to stand at any point C, by sucking or blowing at A. And, if this barometer be kept to the same degree of heat, by putting it in a vessel of sand, it will be very correct for taking small altitudes; for a little alteration in the weight of the atmosphere will make the water at C rise or fall in the tube very sensibly; but if it be suffered to grow warmer, the water will rise too high in the tube, and spoil the use of it; so that it must be kept to the same temperature.

If a barometer was to be made of water put into an exhausted tube, after the manner of quicksilver, it would require a tube 36 feet long or more; which could hardly find room within doors; but then it would go 14 times more exact than quicksilver; because, for every inch the quicksilver rises, the water would rise 14, from whence every minute change in the atmosphere would be discernible. And the water-barometer, above described, will shew the variation of the air's gravity as minutely as the other, if the bottle be large, to hold a great quantity of air.

*The Diagonal BAROMETER* acts on the same principle as the common barometer above described, except that the upper end of the tube is bent at about an angle of  $45^\circ$  from the vertical, whereby the scale of variations is increased in about the ratio of 3 to 2; or more accurately, in the ratio of the diagonal

of a square to the length of its side. If the upper end be bent in a greater angle, the scale of variation will be so much the more increased; but in practice, it is not found convenient to have the angle much exceeding  $45^\circ$ .

*The Horizontal BAROMETER*, consists of a tube bent at right angles, having a pretty wide cylindrical part at the upper end of the vertical leg, which is hermetically sealed, the horizontal leg being open, where, however, the mercury cannot run out, being opposed by the pressure of the atmosphere, the variations of which are indicated by a scale attached to that branch of the instrument.

*The Marine BAROMETER* of Dr. Hooke, is intended to be used on shipboard, being contrived so as not to be affected or injured by the motion of the vessel. It consists of a double thermometer, or two tubes half filled with spirits of wine; the one sealed at both ends, with a quantity of air included; the other sealed at one end only. The former of these is affected only by the temperature of the air; but the other, both by the external temperature, and by the variable pressure of the atmosphere. Hence, considering the spirit thermometer as a standard, the excess of the rise or fall of the other, beyond the former, will shew the increase or decrease of the pressure of the atmosphere. The marine barometer is a very useful instrument for indicating any change in the state of the weather.

*The Pendant BAROMETER* is rather pretty than useful, and consists of a conical tube placed vertically, its upper and smaller extreme is hermetically sealed, and its larger and lower end open: it has no vessel or cistern, its conical figure supplying that defect; for when filled like the rest, there will be as much mercury sustained as is equivalent to the weight of the atmosphere; and as that varies, the same mercury takes up a different part of the tube, and so becomes of a different weight.

*The Portable BAROMETER* is so constructed, that it may be carried from one place to another without damage or derangement. The end of the tube is tied up in a leathern bag, not quite full of mercury, which being pressed by the air, forces itself into the tube, and keeps suspended at its proper height. This bag is usually enclosed in a box, through the bottom of which passes a screw, by means of which the mercury may be forced to the upper end of the tube, and prevented from breaking it by dashing against the top, an accident very likely to happen without this precaution.

*The Reduced BAROMETER* is only three inches long, and serves the purpose of a manometer, in shewing the dilations of the air in the receiver of an air-pump, for which purpose it is now commonly employed.

*The Wheel BAROMETER*, as here represented, was invented by Dr. Hooke, about the year 1668, and is meant to render the alterations in the air more sensible. Here the barometer tube has a large ball, A B, at top, and is bent up at the lower or open end, where an iron ball, G, floats on the surface of the mercury in the tube, to which is connected another ball, H, by a cord hanging freely over a pulley, turning an index, K L, about its centre. In this instrument the variations of the mercury take place in the lower part of the tube; for the height of the mercury being always the difference between its upper and lower surface, and as in this instrument, in consequence of the great diameter of the ball, the mercury can rise but very little in the upper part, it follows that the most obvious variation must take place in the lower branch. Now, when the quicksilver rises in the part F G, it raises the ball G, and the other ball H descends and turns the pulley, with an index round a graduated circle, from N towards M and P, and the contrary way when the mercury and ball sink in the bent part of the tube. Hence the scale is easily enlarged ten or twelve-fold, being increased in proportion to the axis of the pulley, to the length of the index K L. But

then it must be observed, that the friction of the pulley and axis greatly obstructs the free motion of the quicksilver. This imperfection in wheel barometers has been in a great measure obviated by introducing two pulleys, moving on friction wheels.

Various other barometers might here be enumerated, as constructed by Descartes, Huygens, De la Hire, Boyle, Orme, Caswell, Rowning, &c. many of them, however, now out of use, are purposely omitted.

*Phenomena of the BAROMETER.*—The phenomena of the barometer, considered as a weather-glass, have been very differently stated and explained by various writers; and they are so precarious, that it is extremely difficult to form any fixed and general rules concerning them. Although the barometer never fails to indicate a storm, or any great change of weather, for some hours before it occurs; yet its variations afford no indications that are absolutely certain, with respect to those less considerable changes, to which the weather is subject in our variable climate. With certain restrictions they afford some ground for probable conjecture; and these restrictions are to be determined merely by the sagacity of long-continued observation and experience. Strictly speaking, the height of the mercury in the barometer has no immediate and necessary connexion either with rain or fair weather. That its variable height is the immediate consequence of the variable pressure of the atmosphere, is a fact that admits of no doubt; but the causes of this variable pressure have not yet been fully and satisfactorily ascertained; and how far the state of the weather, in all its minute and sudden changes, depends upon it, is a question that is still to be determined. The mercury is commonly highest in winter and lowest in summer; it is least variable at the solstices, and most variable at the equinoxes. The principal observations that have been made on the variations of this instrument, are summed up in the following particulars:—

1. The more considerable elevations and depressions of the mercury in the barometer happen at a very short interval of time, in places very remote from each other. This correspondence was observed by Mr. Derham, in 1699, between the heights of the mercury at Upminster in Essex, and Townly in Lancashire; and afterwards by M. Maraldi, between the variations at Paris and Genoa, at the distance of nearly four degrees of latitude, who adds, during these variations, different winds prevailed at these places. But Mr. Kirwan observes, that where there is a considerable difference of longitude, the like agreement is not found.

2. The deviations of the mercury from its mean annual altitude are far more frequent and extensive in the neighbourhood of the poles than in that of the equator. At Petersburg, in 1725, the mercury once stood at the amazing height of 31.59 inches, if we may credit Mr. Consett; and yet it has been so low as 28.14 inches. In the northern parts of France, the variations are greater than in the southern: at Naples, they scarcely exceed one inch. In Peru, under the equator, and at the level of the sea, they amount only to two or three tenths of an inch; but in other parts, within a few degrees of the line, on the approach of the rainy season, or of hurricanes, the barometer falls an inch or more.

3. The variations without the tropics, are greater and more frequent in the winter, than in the summer months.

4. The variations are considerably smaller in very elevated situations than on the level of the sea. Thus M. Bouguer observed, that on the coast of Peru the variations extended to  $\frac{1}{2}$  of an inch; at Quito, elevated 9374 feet above the sea, they comprehend only 0.087ths of an inch. Saussure made similar observations in Savoy, as did M. Lambert in Switzerland.

5. The mean height of the barometer on the level of the sea, in most parts of the globe hitherto examined, is about 30 inches: M. Bouguer, under the line, observed it at 29.908 inches; but as his barometer was not purged of air by fire, it stood lower than it should have done. Sir G. Shuckburgh, on a mean of several observations on the coasts of Italy and England, found it at 30.04 inches, when the temperature of the mercury was 55°, and that of the air 62°. The mean height of the barometer in London, upon an average of two observations in every day of the year, kept at the house of the Royal Society, for many years past, is 29.88; the mean temperature or height of the

thermometer, according to the same, being 58°. The greatest height observed by Sir G. Shuckburgh, Dec. 26, 1778, in London, was 30.948 inches, the thermometer being at 47°; and, reduced to the heat of 50°, it was 30.957; and this, he says, is the greatest height which, as far as he has been able to collect, it has ever been known to stand at in any country, where observations have been made and recorded, since the first invention of this instrument. In the proximity of the poles, says Mr. Kirwan, the annual mean heights of the barometer differ much more from the standard than in the more southern parts of our hemisphere.

In estimating the connexion of the variation of the barometer with the weather, particular rules have been given by different philosophers; our limits, however, will only allow of stating those of Dr. Halley and Mr. Patrick, which are as follow:—

*Dr. Halley's Rules for judging of the Weather.*—1. In calm weather, when the air is inclined to rain, the mercury is commonly low.

2. In serene, good, and settled weather, the mercury is generally high.

3. Upon very great winds, though they be not accompanied with rain, the mercury sinks lowest of all, according to the point of the compass the wind blows from.

4. The greatest heights of the mercury are found upon easterly or north-easterly winds, other circumstances alike.

5. In calm frosty weather, the mercury commonly stands high.

6. After very great storms of wind, when the mercury has been very low, it generally rises again very fast.

7. The more northerly places have greater alterations of the barometer than the more southerly, near the equator.

8. Within the tropics, and near them, there is little or no variation of the barometer, in all weathers. For instance, at St. Helena it is little or nothing, at Jamaica  $\frac{1}{10}$ ths of an inch, and at Naples the variation hardly ever exceeds an inch; whereas in England it amounts to 2 $\frac{1}{2}$  inches, and at Petersburg to 3 $\frac{1}{2}$  nearly.

Dr. Beal, who followed the opinion of M. Pascal, observes, that, *ceteris paribus*, the mercury is higher in cold weather than in warm; and in the morning and evening usually higher than at mid-day: that in settled and fair weather the mercury is higher than either a little before or after, or in the rain; and that it commonly descends lower after rain than it was before it. And he ascribes these effects to the vapours with which the air is charged in the former case, and which are dispersed by the falling rain in the latter. If it chance to rise higher after rain, it is usually followed by a settled serenity. And that there are often great changes in the air, without any perceptible alteration in the barometer.

*Mr. Patrick's Rules for judging of the Weather.*—These are esteemed the best of any general rules hitherto made:

1. The rising of the mercury presages, in general, fair weather; and its falling, foul weather, as rain, snow, high winds, and storms.

2. In very hot weather, the falling of the mercury indicates thunder.

3. In winter, the rising presages frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw. But in a continued frost, if the mercury rises, it will certainly snow.

4. When foul weather happens soon after the falling of the mercury, expect but little of it; and on the contrary, expect but little fair weather when it proves fair shortly after the mercury has risen.

5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes, then expect a great deal of wet, and probably high winds.

7. The unsettled motion of the mercury denotes uncertain and changeable weather.

8. You are not so strictly to observe the words engraven on the plates, as the mercury's rising and falling; though in general it will agree with them. For if it stands at much rain, and

then rises up to changeable, it presages fair weather; though not to continue so long as if the mercury had risen higher. And so, on the contrary, if the mercury stood at fair, and falls to changeable, it presages foul weather; though not so much of it as if it had sunk lower.

Upon these rules of Mr. Patrick the following remarks are made by Mr. Rowning: That it is not so much the absolute height of the mercury in the tube that indicates the weather, as its motion up and down: wherefore, to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is actually rising or falling; to which end the following rules are of use:

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides, it is a sign that the mercury is then rising.

2. But if the surface be concave, or hollow in the middle, it is then sinking. And,

3. If it be plain, or rather a very little convex, the mercury is stationary: for mercury being put into a glass tube, especially a small one, naturally has its surface a little convex, because the particles of mercury attract one another more forcibly than they are attracted by glass. Farther,

4. If the glass be small, shake the tube; then if the air be grown heavier, the mercury will rise about half a tenth of an inch higher than it stood before; but if it be grown lighter, it will sink as much. And, it may be added, in the wheel or circular barometer, tap the instrument gently with the finger, and the index will visibly start forwards or backwards, according to the tendency to rise or fall at that time. This proceeds from the mercury's sticking to the sides of the tube, which prevents the free motion of it till it be disengaged by the shock: and therefore, when an observation is to be made with such a tube, it ought to be first shaken; for sometimes the mercury will not vary of its own accord, till the weather is present which it ought to have indicated.

**BAROSCOPE**, an instrument for shewing the weight of the atmosphere, frequently confounded with barometer: they are not, however, precisely the same; the one being intended only to shew that the air has weight, whereas the other measures that weight, and determines its true quantity.

**BARREL**, an English vessel or cask, which contains 36 gallons beer measure, and 32 gallons ale measure. The barrel of beer, vinegar, or liquor preparing for vinegar, ought to contain 34 gallons, according to the standard of the ale quart. Barrel is also used as a measure in various commodities; thus,

|                                 |                          |
|---------------------------------|--------------------------|
| Barrel of Essex butter is ..... | 106 lb.                  |
| Barrel of Suffolk butter.....   | 256 lb.                  |
| Barrel { of herrings holds..... | 32 gallons wine measure. |
| and contains about....          | 1000 herrings.           |
| Barrel of salmon holds .....    | 42 gallons.              |
| Barrel of soap is .....         | 256 lb.                  |

**BARREL**, in Machinery, is also applied to any thing hollow and cylindrical, as the barrel of a pump, of a gun, of a watch, &c.

**BARROW**, ISAAC, a very eminent mathematician and divine of the 17th century, was born at London in October, 1630, and died in May, 1677, in the 47th year of his age. He was the preceptor and friend of the celebrated Newton, by whom only, says Dr. Pemberton, he was surpassed in genius and invention. Barrow was the author of a great number of works both on theology and mathematics.

**BARRY**, in Heraldry, is when an escutcheon is divided barwise, or from side to side, into any number of compartments, with tinctures interchangeably disposed.

**BARTER**, is the exchanging of one commodity for another, and forms a rule in the commercial part of arithmetic; is nothing more than simple proportion, or the rule of three, and serves to teach us not to sustain loss in the exchange of goods.

**Rule 1.**—Find the value of that commodity whose quantity is given; then find what quantity of the other, at the rate proposed, you may have for the same money.—2. When one has goods at a certain price, ready money, but in bartering advances it to something more, find what the other ought to rate his goods at, in proportion to that advance, and then proceed as before.

**Example 1.** What quantity of chocolate, at 4s. per lb. must be delivered in barter for 2 cwt. of tea, at 9s. per lb.?

|                              |
|------------------------------|
| cwt.                         |
| 2                            |
| 112                          |
| 224                          |
| 9                            |
| 4)2016 the value of the tea. |

504 lb. of chocolate must be delivered in barter for 2 cwt. of tea at 9s. per lb.

**Example 2.** A and B barter; A hath 20 cwt. of prunes, at 4d. per lb. ready money, but in barter will have 5d. per lb. and B hath hops worth 32s. per cwt. ready money; what ought B to rate his hops at in barter, and what quantity must be given for the 20 cwt. of prunes?

|                                  |                |      |       |
|----------------------------------|----------------|------|-------|
| lb.                              | d.             | d.   | s.    |
| 1 cwt. = 112                     | As 4 : 5 :: 32 |      |       |
| 20                               |                |      | 5     |
| 40                               | 2240           |      | 4)160 |
| 12                               | 5              |      |       |
| —                                | c. q. lb.      | 40s. |       |
| 48(0)1120(0(23 1 9 $\frac{1}{2}$ | Answer.        |      |       |
| 96                               |                |      |       |
| 160                              |                |      |       |
| 144                              |                |      |       |
| 16 = 1 qr. 9 $\frac{1}{2}$ lb.   |                |      |       |

**BASALTES**, in Natural History, a heavy hard stone, chiefly black or greenish, consisting of prismatic crystals, the number of whose sides is uncertain. This mineral always stands upright in columns, and the British dominions present the noblest specimens in the known world of columnar basalt; amongst which, the Giant's Causeway, in Ireland, stands

*Giant's Causeway.*

conspicuous. It consists of three piers of basalt columns, which extend some hundred feet into the sea, surrounded by precipitous rocks, from 200 to 400 feet high, in which there are several striking assemblages of columns, some vertical, some bent or inclined, and some horizontal, and as it were driven into the rock. Bengore, which bounds the Causeway on the east, consists of alternate ranges of tabular and massive, with columnar basalt. But among the various and grand objects on this coast, Pleskin is perhaps the most striking: it presents several colonnades of great height and regularity, separated from each other by tabular basalt; and at Fairhead, the north-east cape of Ireland, and forming the east side of Ballycastle Bay, there is a range of columns of from ten to twenty feet diameter, and between 200 and 300 feet high, supported upon a steep declivity, and offering to the mariner at sea the spectacle of a terrace, which towers nearly 600 feet above the waves that roll beneath. Among the Hebrides of Scotland the isles of Ulva, Gometra and Staffa, and Mull, exhibit massive and columnar basaltes, which abounds in black oxide of iron, and bears a strong resemblance to lava, yet the lava of Mount Etna, in the year 1649, ran into the sea for two leagues and a

half without having the least appearance of being converted into basaltes.

*Chemically analyzed Basaltes and Lava give the following results.*

| Basaltes 100 parts, contain   | Lava 100 parts, contain       |
|-------------------------------|-------------------------------|
| Siliceous earth .....parts 50 | Siliceous earth .....parts 49 |
| Argillaceous ..... 15         | Argillaceous ..... 35         |
| Calcareous ..... 8            | Calcareous ..... 4            |
| Magnesia ..... 2              | Iron ..... 12                 |
| Iron ..... 25                 |                               |
| 100                           | 100                           |

The basaltes of Staffa contains 50 parts of flint; the lava of Catanea Mount Etna, 51 parts; the whinstone of Salisbury Craig near Edinburgh, 46 parts of flint; that of the Calton Hill Edinburgh, 50; and the lava of Sta. Veneve, Etna, 50 $\frac{1}{2}$  parts flint in every 100 parts. These analogies are very singular in these marbles; which have been considered by some as crystallizations from water.

**BASE** of a **FIGURE**, in Geometry, denotes the lowest part of its perimeter; in which sense the base stands opposed to the *vertex*, which denotes the highest part.

**BASE** of a *right-angled triangle*, is properly the hypotenuse, though it is generally used to denote one of the sides about the right angle, the other side being called the perpendicular; this, however, depends totally upon the position of the figure, as, properly speaking, that side which is lowest, or on which the figure stands, is the base; and for this reason that side on which a solid body stands is called the base of a solid.

**BASE** of a *Conic Section*, is a right line in the parabola and hyperbola, formed by the common intersection of the cutting plain and the base of the cone.

**BASE**, in Surveying, is a line measured with the greatest possible exactness, on which a series of triangles are constructed, in order to determine the position of objects and places.

**BASKERVILLE, JOHN**, an eminent artist in letter founding and printing, was born at Woverley in Worcestershire, in 1706, and after bringing the printing of books to its greatest perfection, in Birmingham, he died, without issue, in 1776.

**BASSOON**, a musical instrument of the wind sort, blown with a reed, furnished with eleven holes, and used as a bass in a concert of hautboys, flutes, &c. To render this instrument more portable, it is divided into two parts, whence it is also called a baggot. Its diameter at bottom is nine inches, and its holes are stopped like those of a flute.

**BASTION**, in Fortification, a large mass of earth, faced usually with sods, sometimes with brick, standing out from a

rampart, whereof it is a principal part. The bastion consists of the face, flank, curtain, and gorge, as marked in the figure.

**BATH**, a receptacle of water in which to plunge, wash, or bathe the body; and the water may be either hot or cold, natural or artificial, of fresh water or of salt. In this country we have hot natural baths at Bath, Bristol, Buxton, and Matlock, which are all beneficial in diseases of the head, palsies, cutaneous diseases, scurvy, obstructions, &c. The Russians cure all diseases by hot baths; and now, in Britain, vapour baths, as Captain Jekyll's, (see the next figure,) are becoming very common. The Captain's bath is also a portable machine,

and he carries it about with him, we believe, whenever he removes from his residence in Somersetshire to London.

**BATHING**, immersing the body in hot or cold water, or in steam, made as it were a part of the existence of the ancients. But when the vapour is passed through a cloud of burning perfumes, the bather is extended freely on a couch, and a servant kneads the whole body without causing the slightest pain, and then rubs the skin with a fine glove, till it becomes soft and smooth like silk; it is then indeed that one experiences a universal comfort, and health resulting from cleanliness: the bath adds both to the happiness and longevity of its votaries.

**BATTALION**, a small body of infantry, arranged in form of battle, and ready to engage an enemy. It consists of from 500 to 1200 men, armed with firelocks, swords, and bayonets, divided into 13 companies, one of which is the grenadier company. Some regiments consist of one battalion, others of 2, 3, 4, or 6 battalions.

**BATTERING RAM**, or **ARIES**, an ancient military engine, employed for destroying the walls of fortified places, of which there were three different sorts; the first rude and plain, the others artificial and compound. The first seems to have been nothing more than a great beam, having a heavy head of iron, which the soldiers bore in their arms, and with one end of it assailed the walls by main strength: this of course was worked at a great expense of labour, and without producing any remarkable effect. The second sort, as described by Josephus, consisted of a very heavy beam, headed with iron as above, and suspended in the middle from another strong beam supported

on two posts, which being erected under the walls of the place, was swung backwards and forwards by the soldiers, till, by the repeated shocks thus given, the wall was totally demolished; this machine was sometimes covered by a screen, in order to

protect the soldiers from the assaults of the enemy. The above figure represents the second kind of battering-ram suspended; 2, the ram; 3, the form of its head, fastened to the enormous beam, by three or four bands of iron, four feet in breadth. At the extremity of each of these bands, (4) was a chain (5) of the same metal, one end of which was fastened to a hook, (6) and at the other extremity of each of these chains was a cable firmly bound to the last link. These cables ran the whole length of the beam, to the end of the ram, (7) where they were all bound together as fast as possible with small ropes. To the end of these cables another was fixed, composed of several strong cords, plaited together, to a certain length, and then running single (8). At each of these several men were placed to balance and work the machine. 10, the chain or cable by which it hung to the cross beam (11) fixed on the top of the frame: 12, the base of the machine. The unsuspended ram differed from this, only in the manner of working it; for instead of being slung by a chain or cable, it moved on small wheels, on another large beam.

Plutarch informs us, that Marc Antony, in the Parthian war, used a ram of 80 feet long; and Vitruvius says that they were sometimes 106, and even 120 feet long, and weighed 100,000 pounds; at least this is said to have been the weight of that employed by the emperor Vespasian. These battering rams, by their own weight, and by the action of the men who impelled them, excited a force which in some cases exceeded the utmost effect of our battering cannon. Desaguliers (Lectures, vol. i. p. 65) has demonstrated, that the momentum of a battering ram, 28 inches in diameter, 180 feet long, with a head of cast iron of one ton and a half, the whole ram weighing, with its iron hoops, 41,112 pounds, and moved by the united strength of 1000 men, would only be equal to that of a ball of 36 pounds weight shot point blank from a cannon. And Atwood, comparing the effect of the battering ram, having its metal extremity equal to a twenty-four pounder, with a cannon ball of 24 pounds weight, observes, that in order to their producing the same effect in penetrating a wall or making a breach in it, the weight of the ram must exceed that of the cannon ball in the proportion of the square of 1700, the velocity of the ball, to the square of the velocity with which the battering ram could be made to impinge against the wall, expressed in feet. Estimating this at ten feet in a second, the proportion of the weights will be that of about 2,890,000 to 100, or 28,900 to 1; and therefore the weight of the battering ram must be 346 ton. In this case the ram and the cannon ball, moving with the velocities of 10 and 1700 feet in a second, would have the same effect in penetrating any obstacle; but as the weight of the ram was probably never so great as the above supposition states it to have been, the force of a cannon ball to make a breach in walls must exceed that of the ancient aries; but the momentum of this, or the impetus by which it communicated a shock to the whole building, was far greater than the utmost force of cannon balls; for if the weight of the battering ram were no more than 170 times greater than that of a cannon ball, each moving with its respective velocity, the momenta or forces of both would be equal; but as the weight of this ancient machine was certainly much greater than 170 times that of our heaviest cannon balls, their momentum or impetus to shake or overturn walls and demolish buildings, was much superior to that which is exerted by the modern artillery. And since the strength of fortifications will, in general, be proportioned to the means which are used for their demolition, the military walls of the moderns have been constructed with less attention to their solidity and massy weight, than the ancients thought to be a necessary defence against the aries; that sort of cohesive firmness of texture which resists the penetration of bodies, being now more necessary than in ancient times. The ram was frequently used in the fourteenth century. Sir Christopher Wren employed it in demolishing the walls of the old church of St. Paul, previously to his building the present structure; and found no machine so well adapted to this purpose.

**BATTERY**, in the Military Art, a parapet, thrown up to cover or protect from the enemies' shot, the gunners, and men employed about the guns. In this bank or parapet are cut holes or embrasures, through which the cannon are projected to be fired.

**BATTERY**, in Law, is beating another person unlawfully, for which the remedy is, as for assault, by action of trespass *vi et armis*, as the lawyers term it; wherein the jury will give adequate damages.

**BATTERY**, in Electricity, is a combination of coated surfaces of glass, commonly jars, so connected together that they may be charged at once, and discharged by a common conductor. Dr. Franklin constructed a battery consisting of eleven panes of large sash glass, coated on each side, and connected in such a manner, that the whole might be charged together, and with the same labour as one single pane; and by bringing all the giving sides into contact with one wire, and all the receiving sides with another, he contrived to unite the force of all the plates, and to discharge them at once. Dr. Priestley describes a still more complete battery: this consists of 64 jars, each 10 inches long, and 2½ inches in diameter, all coated within an inch and a half of the top, forming in the whole about 32 square feet of coated surface. A piece of very fine wire is twisted about the lower end of the wire of each jar, to touch the inside coating in several places; and it is put through a pretty large piece of cork, within the jar, to prevent any part of it from touching the side, by which a spontaneous discharge might be made. Each wire is turned round so as to make a loop at the upper end; and through these loops passes a pretty thick brass rod with knobs, each rod serving for one row of the jars; and these rods are made to communicate together by a thick chain laid over them, or as many of them as may be wanted. The jars stand in a box, the bottom of which is covered with a tin plate; and a bent wire touching the plate passes through the box, and appears on the outside. To this wire is fastened any conductor designed to communicate with the outside of the battery; and the discharge is made by bringing the brass knob to any of the knobs of the battery. When a very great force is required, the size or number of the jars may be increased, or two or more batteries may be used. The large and powerful battery of Dr. Van Marum, constructed for Tayler's museum at Haarlem, consists of a great number of jars coated as above, to the amount of about 130 square feet; and the effects of it are truly astonishing. The annexed figure represents a battery consisting of

sixteen jars, coated with tinfoil, and disposed in a proper box. The wires, which proceed from the inside of every four of those jars, are screwed, or fastened, to a common horizontal wire E, which is knobbed at each extremity, and by means of the wires F, F, F, the inside coating of 4, 8, or 12, or of all the sixteen jars, may be connected. The inside of the box which contains these jars is lined with tinfoil. On one side of this box there is a hole, through which a strong wire or hook passes, which communicates with the lining of the box, and of course with the outside coatings of the jar. To this hook a wire is occasionally fastened, which connects it with one branch of the discharging rod, B B C A. By means of the battery, electricity is capable of producing the most powerful effects.

**Experiments.**—A very slender wire, as *x*, being made part of the circuit, will, by the discharge of the battery, instantly become red-hot. It sometimes melts into small globules of different sizes. If between two slips of window-glass some gold-leaf be placed, and the slips of glass be pressed firmly together, and the shock from a battery be sent through them, the gold-leaf will be forced into the pores of the glass. If the gold-leaf be put between cards, and a strong charge be passed through them, it will be completely fused. Gunpowder may also be fired by the electrical battery.

**BATTLE**, a general engagement between two armies, in a country sufficiently open for them to encounter, and at the same time, in front. See WAR.

**BAYER, JOHN**, a German astronomer of the 17th century, who published, in 1603, an excellent work entitled "*Uranometria*," being a celestial atlas, or charts of all the constellations: he first distinguished the stars by the letters of the Greek alphabet, and according to the order of the magnitude of the stars in each constellation. This work was republished by the author in 1627, under a new title, *viz.* "*Cœlum stellatum Christianum*:" here he rejected the old figures of the constellations, and inserted others taken from the scriptures: but this innovation was not relished; and accordingly we find, that in the later editions of 1654 and 1661, the ancient figures and names were restored again.

**BEAMS**, in Naval Architecture, strong thick pieces of timber, stretching across the ship from side to side, to support the decks, and retain the sides at their proper distance, with which they are firmly connected by means of strong knees. They are sustained at each end by thick planks in the ship's side called clamps, upon which they rest.

*Midship BEAM*, the longest beam in a ship, being lodged in the midship frame, or between the widest frame of timbers. At about two-thirds of the height from the keel to the lower deck, are laid a range of beams to fortify the hold and support a platform called the orlop, which contains the cables and stores of the ship. There are usually twenty-four beams on the lower deck of a ship of seventy-four guns, and to the other decks, additional ones in proportion as the ship lengthens above. It is necessary that the beams should have a greater height in the middle than at the two ends, to carry the water more readily off from the decks, and to diminish the recoil of the guns, which will thereby more easily return to their places.

*Orlop BEAMS*, support the orlop deck, but are chiefly intended to fortify the hold.

*On the BEAM*, implies any distance from a ship on a line with the beams, or at right angles with the keel.

*Before the BEAM*, is an arch of the horizon, comprehended between a line that crosses her length at right angles, and some object at a distance before it; or between the line of the beam and that point of the compass which she stems.

*On the Weather BEAM*, on the weather side of the ship.

**BEAM ends**, a ship is said to be on her beam ends, when she inclines very much on one side, so that her beams approach to a vertical position; hence also a person lying down is said to be on his beam ends.

**BEAM of a Balance**, the horizontal piece of iron from the ends of which the scales are suspended.

**BEAM Compass.** See COMPASS.

**BEAR**, *Great and Little*, in Astronomy, the same as *Ursa Major* and *Ursa Minor*, which see.

**BEARD of a Comet**, the rays which it emits in the direction in which it moves, as distinguished from the tail, or the rays emitted or left behind it as it moves along, being always in a direction from the sun. See COMET.

**BEARING**, in Geography and Navigation, the position of one place with regard to another, as estimated by the points of the compass. Thus a place is said to bear north-east, or north-north-east, &c. meaning, that it lies from your present situation in those directions.

**BEER-DRAWING MACHINES** are contrivances by means of which the beer is drawn from several casks at once, from cocks standing in a frame, in the bar of a tavern, or any convenient place above a cellar. These machines are merely an assemblage of small pumps, either sucking or forcing, whose pipes of communication are attached to the lower parts of the respective casks from which the liquor is drawn. The motion is given to the piston sometimes by levers, at others by cranks; but most frequently by means of a hammer-formed lever moving in a vertical plane.

**BEES.** There is no kind of stock in which a purchaser is so easily deceived as that of a hive of bees. The following are the best criterions by which to judge of its value. If a hive be purchased in the spring, it should never weigh less than fifteen pounds; if in the autumn, never less than thirty; and if it be a stock hive, its weight should be forty pounds, for all old hives contain a certain portion of the *bee bread*. Great care should be taken in weighing a hive, lest the comb should be shaken, and so loosened. The middle of the day is the best time to

choose a hive, and the following points should be strictly attended to:

1. The more numerous the bees which enter the hive with yellow balls or pellicles, the better the hive is.
2. The drones should likewise be numerous.
3. The activity of the bees; for if they saunter about, and then re-enter the hive without taking wing, it is a bad symptom.
4. The courage they display in repelling the strange bees.
5. The number of bees who remain at the entrance of the hive fanning with their wings—the greater the internal population: this circumstance is a strong proof of the excellence of a hive.

6. A swarm should always be put into a new hive.

7. The examination of a stock-hive may be pursued with safety, however courageous the bees may appear, by smoking a little tobacco near the hive. But as it may happen that the unskilful apiarian may be stung, the sting should be immediately extracted, and a little goulard water, or laudanum, or sweet oil, instantly applied to it. The mid-day is a better time for the examination of a hive than the evening; and the editor of this work performed this very operation on the day he penned these observations.

*Internal Appearances of a good Hive.*—1. The hive should be crowded with bees.

2. The combs should be yellow; if of a blackish tint, reject it.

3. The side combs should be filled with honey; this may be known by their being sealed up.

4. A number of queen-bee cells (which resemble inverted cupping cups) is a sign that it is a very old hive; it should therefore be rejected.

5. If an unpleasant odour issue from the hive, it is unhealthy. The smell of a healthy hive resembles that of heated wax, partaking at the same time of the fragrance of honey. Two or three bees should, however, be sacrificed, to ascertain the state of the bees: if the substance in the stomach be of a yellowish colour, and smelling somewhat like honey, the bees are in good health; if, on the contrary, it be blackish, with a fetid smell, the dysentery reigns among them.

6. If dark liquid spots are seen on the board of the hive, it is a bad sign; the dysentery is making ravages within; and if a great number of small particles of wax are also observed, the hive is infested with moths.

7. If the wings of the bees are ragged and torn, the hive is old—have nothing to do with it. The hive should be carefully removed in the evening; the hole of entrance should be stopped up with clay, as well as every other crevice through which a bee could make its escape. Let them settle half an hour before the clay is removed. The hives should stand on separate pedestals a yard apart.

Among the various plans proposed for the cultivation of bees, we shall notice in this place Milton's newly invented double-topped Straw Hive.

Proceed to hive a swarm in the lower part of the hive in the usual way, as in the figure. The board at the top must be kept close, by securing the openings by means of a thumb-screw, so that when first hived, the holes of both boards shall not correspond, and by thus turning the upper board, it will prevent the bees from passing through while hiving. At night, bring the hive into the bee-house, or where you intend it should stand; in about two days after, place on the

glasses, as in the figure, (p. 99,) over their respective openings, and stop them round with mortar; after which, turn the board B to admit the bees to ascend for the purpose of working, cover the glasses with the small upper hive, C, and do not look at them for a few days. Indeed, nothing will then be necessary, but to ascertain when they are filled, which is known by the cell being sealed over, which you may expect in about twenty days after a swarm has been hived.

When you wish to take the honey, and to remove all the glasses, turn the board to exclude the bees; then with a thin knife loosen them from the adapter; leave them thus for about an hour: then carry the glasses, inverted, a short distance

from the hive into the shade; or raise the glasses with a small wedge, and those few bees which remain will readily leave, and return to their original hive. This, if effected early in the season, will afford you the opportunity of immediately replacing the same, or another set of glasses, to be again filled.

If you wish at any time to take only one or two of the glasses, with honey, do not turn the board, but loosen such glasses as you are desirous to remove, with a thin knife, set them on a divider, and replace others in their stead. The middle of a fine day is the best time to remove glasses. It will not be advisable to take any honey from the hive after the end of July, as the remaining part of the season might not prove favourable to the gathering enough for winter support; therefore it will be necessary, about this time, or early in August, to remove all the glasses and turn the board, to finally shut them up. It may be well to mention, that those glasses, only partly filled with combs, should be carefully set aside, to be placed on again the following April; if, however, you find the stock will require feeding, you have only to leave one or more of the glasses with honey for that purpose, which is by far the best mode.

Thus much for the swarm, which we now leave till the following April—the time to again commence working the glasses, as hives are now full of combs and brood: should the season prove favourable, you will work the glasses twice or more, and you may calculate upon equal success every subsequent year; but the first season you cannot expect a swarm to fill the glasses more than once, which will produce you 8lbs of the finest honey.—This method of management will not prevent the bees from swarming.

The honey thus obtained will be of the finest quality, pure, free from the young brood, of remarkably fine fragrance, clear, and very superior to any produced from common hives; it may also be taken at pleasure, without injury to the bees; especially, without being obliged to resort at any time to the painful process of smothering these industrious and valuable insects.

*The Double Cottage Straw Hive.*—This hive, for use, will answer many purposes in the keeping of bees, as you may work either a glass or a small straw hive on the top of it, which gives it an advantage over the common hive, although the method of management is simple, and the price easy.

Prepare this hive for a swarm by spreading mortar round the crown, to carry the adapter to support a glass or small straw hive, as you may work with either. Hive the swarm as usual, taking care to secure the opening at the top; after removing it to its appointed place, let the swarm work for ten days; clear the opening at the top, and affix on either a glass or a small straw hive: the bees will then ascend to work. Stop the upper hive round with mortar to the adapter, and darken it with a common hive; in the course of from fifteen to twenty days examine it, and if full, take the honey thus:—pass a knife or wire between the adapter and small hive, to separate the combs; then remove the small hive of honey on a divider, (a tin or brass plate, twelve inches square,) it will then be immediately necessary to place a small hive on the adapter, or stop the opening till you wish to work another hive. Carry the small hive now on the divider a short distance away, or rather into a darkened room; invert it, and place over it a small empty hive of the same size; keep them steady, and, by

tapping round the bottom hive, the bees, in a few minutes, will ascend to the hive above; carry them to within about two yards of their original stock, shake them out, and they will enter again as usual.

*A Superior Box Hive.*—This box hive consists of three divisions, as shewn in the figure, and is so ingeniously constructed, that you may take the finest honey without destroying the bees; you may also work a glass hive on the top, and inspect the whole of their curious and interesting labours without disturbing them.

When you place a swarm in this hive, shut the slider of the adapter F, tie a small cord round to secure the parts, hive the swarm in the usual manner; at night bring it into your bee-house, or appointed place, open the entrance at the bottom, and remove the cord; if you work a glass hive on the top, place it on the same evening, stop it round, draw back the slider to clear the grating, leave it a few minutes, and the bees will ascend for working. Then raise the two upper divisions,

to enable you to remove the bottom division, and by the compression you oblige the bees to work in the glass hive, which should be darkened with its proper cover G, and left for a few days without being looked at: it will be necessary to replace the unemployed division at the bottom four or five days previous to the removal of the glass of honey; in removing which, shut the slider, and leave it in this state for an hour; then follow those plain directions already laid down for the removal of glass and double-topped straw hives.

If you wish to take more honey from this hive than the glass affords, examine the divisions early in September: if the three are full, viz. the two upper hives of honey, and the bottom of combs, and not otherwise, proceed to remove the fillets of the top division, and pass the brass divider between those parts, where it should remain for an hour; then raise the division with a wedge, and draw back the slider of the adapter to let the bees out, and when clear, which will be in a few minutes, remove this division, and place the adapter to the next division, and by withdrawing the divider it will fit close down; when you have taken out the combs of honey from this division, it should be replaced at the bottom; consequently, every year, or once in two years, you give them as it were a fresh division, as in the annexed figure, or part of a hive to rebuild in, which keeps the bees constantly at work, and the combs in a good state of preservation.

*The Hexagon Box Hive and Straw Hive,* with slider and grating, for working a large glass hive on the top, consists of a box, as represented in the annexed figure, having large glass windows, and supporting a glass hive on the top. When well supplied with bees, this hive affords the pleasing opportunity of viewing the progress of their labours, and exhibits a very interesting and beautiful appearance.

To hive a swarm, shut the slider over the grating, and then proceed as before directed. When a glass hive is to be worked, follow the instructions already given with the superior box hive. The hexagon hive is well calculated to work bees from other hives, particularly the common hive, especially when they are in a state of decay; it is effected merely by with-

drawing the slider clear of the grating, and placing the common hive over it in the evening, taking care to stop the entrance of the former with clay. The bees will of course then enter at the bottom, and when they have worked the bottom hive nearly full, which you ascertain by means of the windows, carefully lift them up, and place under them another hexagon hive; consequently, this colony consists of three hives, and it will not be safe to remove the upper hive, unless the bees have worked combs into the bottom hive, which, if effected at the end of the season, you may safely take the common hive, with its contents.

The flat-topped straw hive, described by Mr. Wildman, is directed to be used in a similar manner, answering the purpose only to a certain extent, as it does not admit of windows, to enable you to know when the bees have finally worked down.

*The Common Hive*, as here represented, is in such general use in this country, that it requires but little observation, except on some essential points, which, to benefit the cultivator, ought to be attended to. First, care should be taken to have the hive made of clean and good straw, and manufactured of a suitable thickness. Secondly, a hive should be chosen in proportion to the size of the swarm: and when you have succeeded in obtaining a good hive, and placed a swarm in it, which should fill it to within a rim or two of the bottom, shelter it from cold winds and rain; for if once the wet penetrates a hive, it affects the combs, and the bees, getting a distaste for their home, will work very slowly, and often desert it altogether. It is not material in what aspect the stock stands, provided the sun shines on the hive once in the course of the day. Well-peopled hives kept dry, will thrive in any situation.

One of those fatal incidents to which this hive is subject, occurs through covering it with a hackle or turf, by which you entice the mouse to make a nest on the top, and ultimately eat its way through the crown of the hive, and destroy both combs and bees. About August, the robbing commences by stranger bees and wasps, which is but little regarded: an important benefit will be derived by destroying the queen wasp, seen about April, which is the mother of thousands; much, therefore, is saved in the preservation of those hives which stand the winter.

In September, your attention should be directed to weigh your stocks; none of those of less than from fifteen to twenty pounds in weight can safely be relied on to stand the winter, without feeding; and stop all hives down to the board with mortar.

*Pasturage, or Bee-Flowers.*—Bees are fond of those places where their favourite flowers are to be found; therefore bee-keepers should encourage the growth of such shrubs and flowers as are known to supply honey and wax in the greatest abundance; in most situations bees do not fly far for food, generally not more than half a mile; they may be observed to return with great precipitation to the hive when rain or a storm approaches. The following are the most favourable for pasturage, and those which blossom early are the most desirable:

*Shrubs, &c.*—All fruit trees, lime trees, furze, broom, heath, sallow or gray willow, rosemary, barberry tree, gooseberry, raspberry.

*Flowers.*—Hyssop, mustard; turnips, cabbage, and white clover, left for seed; beans in bloom, mignonette, lemon thyme, garden and wild thyme, borage, winter savory.

Mignonette, borage, and lemon thyme, are the principal, as they continue long in bloom, and afford the finest honey. Rosemary is also a great favourite, but seldom supplies much honey, unless the weather proves very hot and dry when it is in blossom, yet it is worth cultivating, especially in a southern

aspect, being one of the principal aromatic plants from which the bees in the neighbourhood of Narbonne collect their honey, and it is esteemed the finest in Europe. Fields of beans, white clover, and buck-wheat, are of great benefit. Rivers or streams of water are also very beneficial, as bees make use of a great deal of water.

*Swarming*, or the stock-hive casting part of its inhabitants for a fresh colony, depends on the increase of bees, and a queen being ready to lead them. Their breeding begins sooner or later, according to the forwardness of the spring, the fruitfulness of the queen, and the strength of the hive. When bees carry in farina or pellets on their thighs, it denotes they have commenced breeding, which may be as early as February, and not finish till October; and when their numbers are much increased, they shew the indications of swarming, by their clustering in great quantities below the resting board. They never rise but on a fine day, and sometimes will settle, and for some cause return to the stock, probably for want of a queen being with them. Some hives will cast three times, but mostly only twice. The second cast you may expect within three or four days, and never later than ten days after the first. Should a stock overswarm itself, it will perish, unless strengthened; this may be ascertained by observing the quantity of bees afterwards seen to enter. It is necessary in the swarming season, from April to July, particularly in May and June, to observe the hives on a fine day; in general, the bees issue forth in new colonies, about noon—from nine to about three in the afternoon.

*Hiving.*—Bee-keepers should have spare hives prepared to hive the bees as soon as they have settled; for, should the sun shine hot on the swarm, it may take another flight, and you may possibly lose it. The manner of hiving them must be regulated by the nature of the place on which they settle. The custom of preparing hives varies; a clean new hive only requires the loose straw to be rubbed off with a cloth; if any dressing be used, fennel dipped in boiled ale and sugar will best answer the purpose. Have ready a cloth whereon to place the hive, and a wedge to raise it: if the swarm should settle on a branch, shake the best part of it into the hive, place it on the cloth on the ground, and continue to disturb the swarm where it settled, and the hive being left underneath, they will all go in; or cut the branch off, and gently place it in the hive. Should the bees settle on the ground, place the hive over them; and though bees are not apt to sting at this time, the hiving should be performed quietly. Avoid talking and breathing on them, and if you crush any of them they will resent it; therefore, to prevent accident, invariably put on gloves and a veil, which will give you confidence. All swarms are to be sheltered, and left near to where they settle till the evening; thence to be removed very gently to the appointed place.

*Uniting Swarms, and reinforcing Stocks.*—It is essential, when you have weak swarms of bees, that you should strengthen them. The idea so prevalent, of the greatest number of hives producing the most honey and wax, is erroneous; for great part of the bees are necessarily employed in rearing the young, and therefore the number of those who are occupied in collecting honey is not so great as has been imagined; for every swarm, the least as well as the greatest, is provided with a queen, equal in fecundity to the queen of the larger stock, and as the brood she brings continually demands the labour and attendance of nearly half the bees, this circumstance renders the other moiety, from the smallness of their number, unable to accumulate a large quantity of honey in the short time it mostly abounds, and therefore honey cannot be obtained, in glass hives or otherwise, but from a strongly-peopled hive.

*The Method of Uniting:*—Hive the swarms or casts in the usual way, and in the evening spread a cloth on the ground, near the hive to be reinforced; bring the new swarm, and strike it down flat on the ground. The bees will then fall in a cluster; quickly place over them the stock to be reinforced; in ten minutes they will have united and become as one family, to be removed the same evening to its former situation.

*Another Method of Uniting:*—Each cast or swarm to be hived separately; in the evening, turn the crown of the hive into a pail, and set the other hive exactly over it; in the morning, the bees from the bottom hive will have ascended.

The system of uniting, so very important, is but little practised, and has been overlooked by many cultivators; but we are thoroughly convinced, from experience, that it is absolutely necessary to have hives well peopled, and completely sheltered from wet, which are the principal and main objects to be attended to in the art of bee-keeping; and the advantages of uniting swarms will be found particularly beneficial in working the glasses with the newly-invented double-topped hives.

**Feeding.**—With the aid of feeding, it is perfectly easy to bring any hive of bees through the winter; but to ensure the success of a very light stock, it is essential to keep it also very warm and dry. Feeding is absolutely necessary when you have taken more honey than the hive can afford, by the means of small hives or glasses. Such stocks as are intended to be kept through the winter should weigh twenty pounds or upwards, at the end of September; but casts and late swarms seldom attain this weight, unless two or more should have been united. The composition for feeding consists of moist sugar and new beer, in the proportion of one pound of sugar to a pint of beer, simmered to the consistency of treacle: to be inserted into the hives by means of small troughs, at night, and removed the next morning early. Should a hive be very poor and weak, it is better to feed in larger quantities each time.

**Feeding Machine.**—The annexed improved machine for feeding bees, will suit all descriptions of hives:—Prepare a board a little larger than the bottom of the hive, in the centre of which make an opening about ten inches diameter; then form a frame of half-inch deal, to consist of four sides, each about twelve inches by three inches; make the angles firm with small wooden blocks, to which affix the before-mentioned board. A door should then be made in the side of the frame, sufficiently large to admit a deep plate or a small dish, to contain the food. By the use of this machine, the bees are fed quietly, and protected from the cold weather, and the intrusion of other bees. It is scarcely necessary to observe further, that the door of the machine should face such part of the bee-house as best suits your convenience. The dish of food to be placed under should be covered with a piece of thick paper the size of the plate or dish, pierced in holes, through which the bees will feed; and a quantity of short pieces of straw also put into the dish, will prevent the bees from daubing themselves. They should be fed at night, and the dish only taken away early on the following morning; to do this, you should cover your face and hands. The autumn, and early part of the spring, are times proper to examine if any hives require feeding; but always commence before the stock is in absolute want of food, otherwise the bees will be so poor and weak as to be unable to come down.

**Honey.**—Honey differs much, according to the season of the year when gathered; that obtained in the spring is of much the finest quality; the fragrance and richness of which depends greatly on the pasturage. To judge of the best honey, it should be of a bright pale colour, thick, and a little aromatic. To obtain it from the combs in its pure state, it must be left to run from them without pressing. The properties of honey are much esteemed, and have been noticed by an eminent French physician, Dr. Lemery. in a treatise on foods, in which he says, "Honey heats and strengthens the stomach, is of a lenitive nature—produces nourishment, helps respiration, and is particularly good for those of cold and phlegmatic constitutions."

The newly invented double-topped straw hive, and the other hives described in this article, and every necessary apparatus connected with the apiary, may be obtained at the Repository, 175, Strand; but the following instructions are from Huish's work on bees; and the Huish Hive, which differs entirely from the above, may be had at No. 205, Piccadilly.

Huish's hive is of straw, and resembles a flower-pot inverted, as represented in the annexed figure, with a convex covering of straw also. When the top *a* is removed, several laths are

seen, as in *b*, to which the bees attach their combs, and are prevented from getting up into the top by means of a net which

covers the laths. *c* represents a lath and comb attached to it, which may be easily removed, according to the following instructions for September.

**January.**—The bees begin to shew some small degree of activity in this month, when the weather is fine, if they are well. The snow should be carefully brushed off the tops of the hives, and it will be of service to the bees to turn the hives carefully up when the day is warm, and admit a portion of pure air into them. Bad smells and bad air are as prejudicial as bad food to bees. If the bees shew symptoms of dysentery, salt and port wine should be mixed with their food, or diluted brandy.

**February.**—Bees should be well fed with the following syrup. A pint of ale, a pound of sugar, half an ounce of salt, boiled well, and carefully skimmed: when cold, this mixture will be of the consistence of honey. The stools should be cleaned this month, and sprinkled with salt. The mouth of the hive, which in September was contracted, in order to exclude insects and field mice, should now be enlarged, yet this should only be permitted when the weather is fine; if a fall of snow should again take place, it should be closed,—this should be effected so as to prevent the egress of the bees, but not so as to prevent a circulation of air. A piece of open canvass might be strained over a little frame, and fastened above the hole, which might be raised or lowered at pleasure. In the Huish hives, these slides are of tin. Water should be plentifully supplied in troughs, if no streamlet is at hand, pebbles being placed in it to serve as resting places for the bees.

**March.**—If, as it frequently happens, the bees of a hive appear languid and weak, and the most generous food appears to be thrown away upon them, the queen of that hive is barren, and the cells are devoid of any fecundated eggs of the last season; they should therefore be joined to the next inferior stock in the apiary. To effect this, the top of the hive to which the bees are to be joined, must be cut off, and the combs laid bare; this is a nice operation, for with the greatest care, much damage will incur; the weak hive must then be well plastered to the lower one, and every crevice filled so as to permit no egress to the bees, except through the entrance of the lower hive. The bees should be fed in the evening, and in the morning the surplus should be removed. The mouth of the hive may now be left at its usual size. Stock hives should be purchased this month. The hives should be kept warm, or sheltered. Young bees may now be seen about the entrance of the hive; the old bees may also be observed cleaning them with their proboscis.

**April.**—The business of the hive increases daily, and the sight of the first drone should be considered a holiday, as he is the harbinger of a swarm. New hives should be kept in store, to be at hand when wanted. All superfluous and rough straws should be carefully cleared from the interior of the hives, and holes, if any there are, should be stopped with putty or mortar. Singeing or friction will remove the straws—the former is perhaps the best method. The little speckled butterflies now hover about, to steal into the hives, that they may there deposit their eggs. These should be watched, and destroyed.—The queen wasp often appears this month, and should, if possible, be destroyed. If a hive is attacked either by bees or wasps, the only real way to assist its inhabitants is, by remov-

ing the hive far away in the evening, and putting an empty one in its place. Some hives will swarm in April, but this is considered rather early.

*May.*—The bees now becoming very numerous in a healthy hive, many of them fan at the entrance, to refresh their inmates; besides which, small drops of perspiration may be seen on the board, and an increasing blackness also. The clustering of the bees round the mouth of the hive for two or three days together, sometimes at the mouth of the hive, foretells the swarming; and if bees are carefully watched, two or three may be observed, and sometimes more, wandering about, and examining particular objects.

The most usual time of swarming is between the hours of nine A.M. and two P.M. They never swarm while the day is clouded, or in high winds. Yet a sudden gleam of sunshine will oftentimes tempt them to choose their new habitation, even in inclement seasons. All the clatter made by pokers and shovels is absolute nonsense, and would tend rather to scare the bees than settle them; their flight should be watched, and when once they settle, the hive should, if possible, be held under them—a goose wing is of great service in brushing them off; but if they attach themselves to a twig which can be cut off, this should be done. The hive should be well rubbed inside with strong beer, sugar, and salt, as before described; though it is the opinion of some apiarians, that no such preparation is necessary. A good swarm should weigh six pounds: its weight is easily ascertained by weighing the empty hive first. Should a hive appear destitute of drones, some must be caught as they are about to enter other hives, and at evening they must be placed at the entrance of the hive supposed to be destitute of them.

*June.*—Second swarms take their flight this month; but they give no signs of their departure, and therefore should be well watched. A second swarm is not worth much, but two such swarms together make a good one. The two swarms may be swept into the same hive, and one of the queen bees will be killed by the strongest. But if the proprietor has skill and courage enough to do it, he should kill one of the queen bees himself. Second swarms may be returned to the parent hive in the following manner:—Place the back of a chair parallel with the entrance of the hive, spreading over it a table-cloth, then holding the hive, containing the second swarm, over this, give it a gentle tap or two; the bees will fall on it, and may be gently impelled to their old habitation by a feather or stick. A first swarm commences the construction of the comb in the middle of the hive; the second swarm, at the sides.

*July.*—The hives should be shaded this month from the intense heat of the sun, to preserve the wax, and consequently the honey. Some persons extract some of the comb at this season of the year. A bee entering the hive with honey, is of a cylindrical form, and of a glossy appearance. The bee without honey, is sun-broiled and wrinkled. When the latter appear numerous, and a correspondent proportion of bees without the pellets of wax are also seen, the hive to which they belong is in a decaying state. Those hives in which the drones are first destroyed, are of particular value.

*August.*—In those counties where they suffocate the bees, the operation is carried into effect in this month, upon the supposition, that the little creatures begin to live upon their stock; but this is erroneous: if the season is mild, they find food till October. The common spider commits great devastation this month, and care should be taken to destroy him. The entrance of the hive should also be closed, so as to prevent more than two bees entering at the same time, in order to exclude other robbing bees and wasps. The usual way, however, is, to offer a reward for every wasp not destroyed. The humble-bee may also be considered an enemy, since it consumes four times the quantity of the mellifluous juice of flowers than the hive bee. The hives should not be molested during this month, more than can be helped, or than is necessary for their preservation against the attacks of their enemies.

*September.*—This is the month in which many apiarians take a part of the honeyed store, and the following is the most approved method for effecting this difficult task:—In the first place, no hive should be incommoded by sticks. Presuming that this is not the case, the hive should be carefully turned

up; some tobacco being at hand ready for fumigation, the bees will then lose all their courage, and retreat into the corners of the hive; and if they recover from their stupor, a second application of the tobacco will quiet them. The comb should then be carefully cut out, but sparingly. The middle combs should not be touched. When two weak hives are to be joined, Mr. Huish recommends that both should be stupefied by fumigation, and one of the queen bees carefully discovered and killed, the hive to which she belonged being carefully swept into the other. It is the opinion of some apiarians, that the bees should be assisted in the destruction of the drones. The hive should be carefully examined, the stool cleaned, and strewed with salt. Contract the entrance, and plaster the hive to the stool, to keep out all foreign enemies.

*October.*—Bees should be well fed this month, with the syrup mentioned in February. The tops of the hives should be examined, and protected from all damp and inclemency of the weather. Cleanliness is absolutely necessary to the prosperity of bees. The entrance should be again contracted, so as to admit only one bee.

*November.*—The hives should be carefully attended to, and care should also be taken that they have plenty of food. This may be ascertained by occasionally weighing the hive upon the board on which it stands, and marking the decrease of weight. Great cold will affect the bees, and reduce them to a state of torpor, which will end in death, unless relieved by a removal to a warmer situation. Every scattered benumbed bee should be attended to, collected, and when restored to animation by gentle warmth, should be placed at the mouth of the hive, when it will gladly enter. They should be collected in a handkerchief; not in any glazed substance. The field mouse should be watched, and all other vermin and insects; and the hives, if in an exposed situation, should be fastened by a rope to the stand, lest the wind, which frequently happens, should blow them down.

*December.*—All that the apiarian has to attend to this month, is to keep his hives clear from snow, and confining the bees to their dwelling; and the less they are disturbed in cold weather, the better, since they are kept alive in winter by a reciprocity of animal heat, which is of course diminished if they are compelled to separate, or are shaken.

**BELL METAL**, of which bells are made, is composed of three parts of copper and one of tin. See **FOUNDRY**.

*The Diving Bell.*—To illustrate the principle of this machine, take a glass tumbler, plunge it into water with the mouth downwards; you will find that very little water will rise

into the tumbler; which will be evident, if you lay a piece of cork upon the surface of the water, and put the tumbler over it; for you will see, that though the cork should be carried far below the surface of the water, yet that its upper side is not wetted, the air which was in the tumbler having prevented the entrance of the water; but as air is compressible, it could not entirely exclude the water, which, by its pressure, condensed the air a little.

The first diving-bell of any note was made by Dr. Halley. It is most commonly made in the form of a truncated cone, the smallest end being closed, and the larger one open. It is weighted with lead, and so suspended that it may sink full of air, with its open base

downwards, and as near as may be parallel to the horizon, so as to close with the surface of the water. Mr. Smeaton's diving-bell was a square chest of cast iron, four feet and a half in height, four feet and a half in length, and three feet wide, and afforded room for two men to work in it. It was supplied with fresh air by a forcing pump. This was used with great success at Ramsgate. Other contrivances have been used for diving-bells.

The first diving-bell we read of in Europe was tried at Cadiz, by two Greeks, in the presence of Charles V. and 10,000 spectators. It resembled a large kettle inverted. The first

person who brought the diving-bell into vogue with us was Phipps, the American blacksmith, in the reign of Charles II., and who, from the fortune he acquired from a Spanish ship, to which he went down, laid the honours of the Mulgrave family. The following is the most useful purpose to which the diving-bell has been applied.

*Diving-Bell at Port Patrick.*—The diving-bell, or rather the improved instrument now in use at Port Patrick, is neither more nor less than a square cast-metal frame, about 8 feet high, 22 feet in circumference, and weighing upwards of four tons. This frame is, of course, open below, and at the top are twelve small circular windows made of very thick glass, such as are sometimes seen used on board of ships. These windows are so cemented or puttied in, that not a bubble of water can penetrate; and when the sea is clear, and particularly when the sun is shining, the workmen are enabled to carry on their submarine operations without the aid of candles, which would consume nearly as much air as an equal number of human beings. In the inside of the bell are seats for the workmen, with knobs to hang their tools on; and attached to it is a strong double air-pump, which is a mighty improvement on the old-fashioned plan of sinking barrels filled with air. From this pump issues a thick leathern tube, which is closely fitted into the bell, and the length of which can easily be proportioned to the depth of water. As may be supposed, the bell is suspended from a very long crane, the shaft of which is sunk to the very keel of a vessel, purchased and fitted up for the purpose, and which is, in fact, a necessary part of the diving apparatus. On the deck of this vessel is placed the air-pump, worked by four men, with an additional hand to watch the signals. When about, therefore, to commence operations, the sloop is moved to the outside of the breakwater, the air-pump put in motion, the crane worked, and then go down the aquatic quarrymen. From its weight and shape, the machine must dip perpendicularly; while the volume of air within enables the workmen to breathe, and keeps out the water. On arriving at the bottom, the divers are chiefly annoyed with large beds of sea-weed, although, from the inequalities of the channel at Port Patrick, and the partially uneven manner in which the ledges of the bell occasionally rest on the rocks, it is impossible to expel the water altogether; and this, it is presumed, is the reason why it is dangerous to descend in rough or squally weather, when the heaving and agitated deep would be apt to dash in at the smallest cranny. To guard against the effects of several hours' partial immersion in water, the men are provided with large jack-boots, caps of wool, and coarse woollen jackets. They also observe the precaution of stuffing their ears with cotton, as the constant stream of air which descends from above, occasions, at first, an uneasy sensation, and is even apt to produce deafness. The chief submarine artist came from Holyhead; and out of 180 masons, carpenters, and labourers, only one man, it is said, volunteered to assist him. A respectable and ingenious gentleman, who had been down in the bell, stated, that he felt no inconvenience whatever; but the air-pump workers, among whom were made some minute inquiries, shook their heads at this piece of information, and hinted, that the volunteer-diver had often felt a little queerish, and, for one thing, "had taken his victuals very badly." Here, then, we have two or three men working with perfect ease and safety 20, 25, and sometimes 30 feet below water. In carrying out the new pier, it is necessary to make a bed for the foundation stones, which would otherwise be left at the mercy of the waves—and this, in a word, is the duty of the divers. With picks, hammers, jumpers, and gunpowder, the most rugged surface is made even, and not only a bed prepared for the huge masses of stone which are afterwards let down, but the blocks themselves strongly bound together with iron and cement. The divers, like other quarrymen, when they wish "to blast," take good care to be put out of harm's way. By means of a tin tube, the powder is kept quite dry, and a branch from the larger cavity, hollow and filled with an oaten straw, is lengthened to the very surface of the water before the fuse is lighted. In one or two cases the powder has failed to explode, and it is very teasing for the men, after three or four hours' hard work below water, to be compelled to descend again, for the sole purpose of repeating the blasting process.

**BELLEROPHON**, a name sometimes given to the constellation Pegasus.

**BELLOWS**, an instrument constructed for the purpose of alternately drawing and expelling air. In the common culinary bellows the air rushes in at a hole or holes at the bottom, called feeders, over which is a flapping valve, and is expelled through a conical pipe called the nozzle, by means of a kind of mechanism too well known to require description here.

Dr. Gregory observes, that it is not the impulsive force of the blast that is wanted in most cases, but merely the copious supply of air to produce the rapid combustion of inflammable matter; and the service would, in general, be better performed if this could be done with moderate velocities and extended surface. What are called air-furnaces, where a considerable surface of inflammable matter is acted on at once by the current which the mere heat of the expended air has produced, are found more operative, in proportion to the air expended, than blast-furnaces animated by bellows. There is, indeed, a great impulsive force required in some cases; as, for blowing off the scoriæ from the surface of silver or copper in refining furnaces, or for keeping a clear passage for the air in great iron furnaces. But, in general, we cannot procure this abundant supply of air in any other way than by giving it a great velocity by means of a great pressure or impulse; the air is admitted into a very large cavity, and then forcibly expelled from it through a small orifice.

The method of producing a continual blast by a centrifugal force has been long known. Anacharsis, the Scythian, is recorded as the inventor of bellows. But the first bellows acting upon this principle, of which we have a distinct account, is that invented by M. Teral, in 1729, and represented in the following figure, where A B is a cubical box, with a top rather

arched: to this box is adapted a hollow pyramidal frustum C, at the extremity of which is the tube or nozzle D; the capacity of the pyramid not being separated from that of the box. This box contains an arbor or shaft carrying vanes, as G F, posited horizontally, and which are here placed, as it were, out of the box, that their shape and number may be seen. The ends of the arbor run in a proper collar on each side of the box, and one end, as F, passes through the side of the box, and carries a pulley: over this pulley passes a cord or band, which also runs round part of a wheel H I, situated at some distance from the bellows, and which is turned by the handle M. Thus it will be manifest, that as this handle turns the wheel H I, it will, by means of the band, turn the pulley F and the arbor and vanes, with a velocity which will be to that of the wheel as the radius of the wheel to that of the pulley. Hence the greater diameter of the wheel, and the less that of the pulley, the more rapidly will the exterior air (which enters by small holes h h, into the top of the box,) be driven by the vanes, and compressed into the truncated pyramid c, and thence expelled at D, in a continued blast; which will likewise be the more violent the greater the action at the handle M. This machine, being very simple, is easily constructed, and at a small expense.

Another bellows, furnishing a uniform blast, is described as follows:—One cylinder is made to deliver its air into another cylinder, which has a piston exactly fitted to its bore, and

loaded with a sufficient weight. The blowing cylinder A B C D, (as represented in the figure below,) has its piston P worked by a rod N P, connected by double chains with the arched

head of the working beam N O, moving round a gudgeon at R. The other end O of this beam is connected by the rod O P with the crank P Q of a wheel-machine; or it may be connected with the piston of a steam-engine, &c. &c. The blowing cylinder has a valve or valves E in its bottom, opening inwards. There proceeds from it a large pipe C F, which enters the regulating cylinder G H K I, and has a valve at top, to prevent the air from getting back into the blowing cylinder A B C D. It is evident, that the air forced into this cylinder, G H K I, must raise its piston L, and that it must afterwards descend, while the other piston is rising. It must descend uniformly, and make a perfectly equable blast.

We may observe, however, that if the piston L be at the bottom when the machine begins to work, it will be at the bottom at the end of every stroke, if the *tuyere* T emits as much air as the cylinder A B C D furnishes; nay, it will lie a while at the bottom, for, while it was rising, air was issuing through T. But as this would make an interrupted blast, it is prevented thus: The orifice T must be lessened; yet then there will be a surplus of air at the end of each stroke, and the piston L will rise continually, and at last get to the top, and allow air to escape. But it is possible to adjust circumstances, so that neither shall happen. This is done easier by putting a stop in the way of the piston, and putting a valve on the piston, or on the conducting pipe K S T, loaded with a weight a little superior to the intended elasticity of the air in the cylinder. Therefore, when the piston is prevented by the stop from rising, the shifting valve, as it is called, is forced open, the superfluous air escapes, and the blast preserves its uniformity.

The *Hydraulic Forge BELLOWS*, of Mr. J. C. Hornblower, a very ingenious contrivance, is thus described. This invention is shewn in the following engraving:—A the plunger, or working part of the bellows, 18 inches square within, which receives the air by a valve in the hinder part opening inwards, which at the stroke by the rockstaff E throws it down the tube indicated by the dotted lines, which has a valve opening into the reservoir D, whence it is led to the *tuyere* by the pipe P. Length of the plunger 20 inches, stroke nine inches. Diameter of P three inches; of the nozzle 0.6. The whole is placed in a pit or cistern, having water sufficient to rise to the lower end of the tube where the valve hangs; this tube is the only communication between the upper part and the reservoir D: when as much water is poured in round the working part, over the wash-boards, as will rise within five inches of the upper edge of them, the bellows is ready for use. The little frame-work serves to keep it from rising, and affords a convenient support for the balance and the rockstaff. The area of the pit or cistern ought to be at least twice as much as that of the plunger A.

A very striking difference between the effect of this bellows

and a common leathered 30-inch bellows in the same shop, is the following. The leathered bellows throws considerably more air to the fire, and its nozzle, compared with this, is as .73 to .60 in diameter, but it does not produce so great an effect in bringing on the heat, and the noise of this is so great as almost to drown that of the common one. The only difference in other respects is, that in the hydraulic bellows the pipe goes under eight feet, and the conducting pipe of the other comes down about the same distance from the shop above.

When bellows are made more than usually large, for extensive furnaces, they have been frequently work-

ed by water-wheels. But iron furnaces have, of late, been constructed of such magnitude, that no leather bellows could be made sufficiently capacious; and hence large forcing pumps have been substituted for them. We shall, under the article *FORGE*, describe the Carron engine constructed by Smeaton.

*Hydrostatic BELLOWS*, (as represented in the annexed figure,) is a machine for illustrating the upward pressure of fluids. It

the weights, though the water in the pipe, should not weigh a quarter of a pound. For the narrower the pipe the better, beyond certain limits, provided we may make it long enough, the proportion being always this:

As the area of the orifice or section of the pipe,  
To the area of the bellows' board, E F;  
So is the weight of water in the pipe A G,  
To the weight it will sustain on the board C D.

For the fluid at B, the bottom of the tube, is pressed with a force varying as its altitude A B; and this pressure is communicated horizontally to all the particles in the space F E, and then distributed equally throughout the fluid in the bellows; consequently, the pressure upwards at F E is equal to the weight of a cylinder of the fluid whose base is F E, and altitude A B; while the actual weight of water borne up is only that of the cylinder, whose base is F E, and height B G; and hence no weights laid upon C D that do not exceed the weight of a

cylinder of the fluid, whose base is EF and altitude AG, will disturb the equilibrium.

**BELLOWS**, or *Water Blowing-Engine*, is a machine in which the stream of air is supplied by the flowing of the water, and it has been long employed at the iron works of Poullaouen in France. The shower of water, in its descent through the vertical pipe of the machine, carries down a column of air along with it, (upon the principle of the lateral adhesion of fluids,) in the same manner as a shower of rain on the surface of the sea, produces that temporary blast of wind which the seamen term a *squall*. The effects of this machine in producing a blast of air, are inferior to that of the steam-engine; but in situations which afford a plentiful supply and a sufficient fall of water, it may frequently be employed with advantage.

**BELTS**, *Fascia*, in Astronomy, zones or girdles, surrounding the planet Jupiter, more lucid than the other parts of his body, and terminated by parallel straight lines, being sometimes broader and sometimes narrower, varying both in magnitude and position. Dark spots have frequently been observed in Jupiter's Belts, one of which is permanent, and by means of which the diurnal revolution of this planet has been ascertained. See Phil. Trans. No. 10 and No. 11, vol. lxiii. Some astronomers suppose the belts to be seas, which alternately cover and leave bare vast tracts of this planet; and that the spots are gulfs in those seas, probably as large as our ocean, sometimes full and at others dry. Other hypotheses have been advanced by different astronomers, which, however, are all merely conjectures, and therefore excite but little interest. These belts were first observed at Naples by Zuppi and Bartoli, two jesuits, and afterwards by Campani and Huygens. Cassini observed, also, three dark straight parallel belts on the disc of Saturn; and something of a similar kind has been seen indistinctly on the planet Mars.

**BENDING**, the reducing a body to a curved or crooked form. The bending of boards, planks, &c. is effected by means of heat, whether by boiling or otherwise, by which their fibres are so relaxed, that they may be bent into any figure at pleasure. Bernoulli has a discourse on the bending of springs or elastic bodies, and Amontion gives several experiments on the bending of ropes.

**BENITHNASH**, a name sometimes given to the last star in the tail of Ursa Major.

**BERKELEY**, DR. GEORGE, a celebrated divine and philosopher, was born at Kilarin in Ireland, 1684, and died at Oxford, 1753, in the 69th year of his age. He was author of several works on theology, mathematics, and metaphysics.

**BERNE MACHINE**, (as in the following figure,) for rooting up trees, the invention of Peter Sommer, of Berne, consists of

three parts, the beam, the ram, and the lever. The beam, A B C, No. 1, of which only one side is seen in the figure, is composed of two stout planks of oak, three inches thick at least, and separated by two transverse pieces of the same wood, at A and C, about three inches thick: these planks are bored through with corresponding holes, to receive iron pins, upon which the lever acts between the two sides of the beam, and which is shifted higher and higher as the tree is raised, or rather pushed out of its place: the sides are well secured at the top and bottom by strong iron hoops. The iron pins on which the lever rests, should be an inch and a quarter, and the holes through which they pass, an inch and a half, in diameter. The position of these holes is sufficiently indicated by the figure. The foot of the beam, when the machine is in action, is secured by stakes represented at G, driven into the earth. The ram, D, which is made of oak, elm, or some other strong wood, is capped with three strong iron spikes represented at f, which take fast hold of the tree. This ram is six or eight inches square, and a slit is cut lengthwise through the middle of it, from its lower end at K, to the first ferule a, in order to allow room for the chain g h to play round the pulley K, which should be four inches thick, and nine inches in diameter. This ram is raised by means of the chain g h, which should be about ten feet long, with links four inches and three-quarters in length, and an inch thick. One end of this chain is fastened to the top of the beam at C, while the other, after passing through the lower part of the ram, and over the pulley K, terminates in a ring or link represented in No. 3; the two ears, m, n, of which, serve to keep it in a true position between the two planks of the beam. In this ring, the hook p is inserted: the hook is represented in profile, No. 2, where F is the part which takes hold of the ring. But it must be observed, that the parts of this machine represented in Nos. 2, 3, are drawn on a scale twice as large as the whole engine. The hook F, No. 2, should be made of very tough iron, as well as the handle D, and the arch E C. This handle should be two inches thick at z, where it joins to the hook, and the thickness gradually lessen by degrees up to the arch, which need not be more than half an inch thick. On each side of the pin z is a semicircular notch x y, which rests alternately on the pins when the machine is worked. The hole D, and the arch E C serve to fix a long lever of wood E F, No. 1, by means of two iron pins; and by this contrivance, the lever is either raised or depressed at pleasure, in order to render the working of the machine easy in whatever part of the beam the lever may be placed; for without this contrivance, the extremity of the lever E F would, when the handle is near the top of the beam, be much higher than men standing upon the ground could reach. It must, however, be remembered, that the lever is often shortened by this contrivance, and consequently its power lessened. The machine is worked in the following manner:—It is placed against a tree, in the manner represented in the figure, so that the iron spikes at f may have hold of the tree, and the end of the beam A be supported by stakes represented at G. The iron handle, No. 2, is placed in the opening between the two planks of the beam, and the wooden lever fixed to it by means of the iron pins already mentioned. The hook F takes hold of the chain, and one of the iron pins is thrust into the outer row of holes, by which means the outer notch x will rest on the pin, which will be now the centre of motion; and the end of the lever E, No. 1, being pressed downwards, the other notch y, No. 2, will be raised, and at the same time the chain, and consequently the ram. The other iron pin is now to be thrust into the hole in the inner row, next above that which was before the centre of motion, and the end of the lever E elevated or pushed upwards, the latter pin on which the notch y rests, now becoming the centre of motion. By this alternate motion of the lever, and shifting the pins, the chain is drawn upwards over the pulley K, and consequently the whole force of the engine exerted against the tree: there is a small wheel at L, in order to lessen the friction of that part of the machine. From this account the reader will very easily perceive, that the machine is nothing more than a single pulley compounded with a lever of the first and second order. It must, however, be remembered, that as the push of the engine is given in an oblique direction, it will exert a greater or lesser force against the horizontal roots of the tree,

in proportion to the angle formed by the machine with the plane of the horizon, and that the angle of  $45^\circ$  is the maximum, or that when the machine will exert its greatest force against the horizontal roots of the tree.

**BERNOULLI**, the name of several excellent mathematicians of France and Switzerland.

**BERYL**, a pellucid gem of a bluish green colour, found in the East Indies, Peru, and Silesia. This gem assumes either the pebble or columnar, or crystal form. To imitate beryl, artists add to 20 lbs. of crystal glass made without magnesia, 6 ounces of calcined brass or copper, and a quarter of an ounce of prepared zaffre.

**BIENNIAL PLANTS**, are those which endure two years; as, of esculents, the cabbage, savoy, carrots, parsnips, beet, onion, leek; of flowers, carnation, hollyhock, wallflower, &c.

**BILBOES**, long bars or bolts of iron with shackles sliding on them, and a lock at the end, used to confine the feet of prisoners in a manner similar to the punishment of the stocks. The offender is laid in irons, which are more or less ponderous according to the nature of the offence of which he is guilty.

**BILGE**, or **BILDGE**, that part of a floor in a ship which approaches nearer to an horizontal than to a perpendicular direction, and on which the ship would rest if laid on the ground; hence, when a ship receives a fracture in this place, she is said to be bilged, or bulged. Bilge is also the largest circumference of a cask, or that which extends round by the bung-hole.

**BILGE-water**, the rain or sea-water which occasionally enters the lower apartments of a ship, whence running down to the floor, it remains in the bilge of the ship, till pumped out, by reason of her flat-bottom, which prevents it from going to the well of the pump, and is always (if the ship does not leak) of a dirty colour, and disagreeable smell.

**BILLION**, in Numeration, the sum of a million of millions, or 10000-0000-0000: this term, as well as those of trillion, quadrillions, &c. are introduced for the more readily expressing in words, or enumerating, a number consisting of many figures; but they have been differently employed by different writers; the French mathematicians understanding billion to mean thousands of millions, and the English millions of millions; thus, in Bezout's "Course of Mathematics," and the "Encyclopédie Méthodique," the place of billions is said to be the tenth from the right towards the left, whereas we make it in our arithmetics the thirteenth; and it is singular, that this word is not found in any English dictionary. Mr. Bonnycastle, in his arithmetic, uses the phrase bi-million or billion, tri-million or trillion, which seems to be the probable derivation of these terms; and admitting this, there can be no doubt, from analogy, that bi-million or billion means a million times a million, the same as biquadratic means a quantity produced from the multiplication of two quadratics. The French have, however, decidedly the advantage in point of simplicity.

**BIMEDIAL LINE**, in Geometry, is the sum of two medials. Thus, when two medial lines, commensurable only in power, and containing a rational rectangle, be compounded, the whole shall be irrational with respect to either of the two; and is called, by Euclid, a first *bimedial line*. But if two medial lines, commensurable only in power, and containing a medial rectangle, be compounded, the whole will be irrational; and is called a second *bimedial line*. Euclid, lib. x. prop. 38 and 39.

**BINOCLE**, or **BINOCULAR TELESCOPE**, is a telescope to which both eyes may be applied; and, consequently, the same object observed at the same time with both. It consists of two tubes, with two sets of glasses of the same power, and adjusted to the same axis; which has been said to exhibit objects larger and more distinct than a single or monocular glass. But this is probably only an illusion, occasioned by the stronger impression which two equal images, alike illuminated, make upon the eyes. There are also microscopes of the same construction, but they are very seldom used.

**BINOMIAL**, in Algebra, is a large quantity consisting of two terms or names, and connected by the sign *plus*, *minus*, or *= equal*; thus,  $a + b$ ,  $a - b$ ,  $a = b$ , are all binomials; the difference  $a - b$ , being also frequently called a *residual*; and by Euclid, *apotome*. The terms binomial and residual are said to have been introduced into algebra by Recorde, in 1557;

and they have since been very commonly employed in various ways. Thus we say, *Binomial Curve*, *Equation*, *Surd*, *Theorem*, &c.

**BINOMIAL Theorem**, is a general algebraical expression or formula, by which any power or root of a quantity of two terms is expanded into a series. This is also commonly called the *Newtonian theorem*, or *Newton's binomial theorem*, on account of his being commonly considered as the inventor of it, as he undoubtedly was, at least in the case of fractional and negative indices; which includes all the other particular cases of powers, divisions, &c. This celebrated theorem, as proposed in its simplest form, is this:—Let  $a + b$  be raised to the fourth power.

| The Powers.  | Mode of Expressing them. | Powers Expanded.                                             |
|--------------|--------------------------|--------------------------------------------------------------|
| Square ..... | $(a + b)^2$              | $a^2 + 2ab + b^2$                                            |
| Cube .....   | $(a + b)^3$              | $a^3 + 3^2 ab + 3ab^2 + b^3$                                 |
| 4th Power .. | $(a + b)^4$              | $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$                        |
| 5th Power .. | $(a + b)^5$              | $a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5$            |
| 6th Power .. | $(a + b)$                | $a^6 + 6a^5b + 15a^4b^2 + 20a^3b^3 + 15a^2b^4 + 6ab^5 + b^6$ |
| &c.          | &c.                      | &c.                                                          |

The first term  $a$  is raised to the 6th power, and the second term  $b$  to the same power. In all the intermediate terms the powers of  $a$  decrease, and the powers of  $b$  increase, by unity, in each successive term. In each case, the co-efficient of the second term is the same with the index of the given power. Thus, in the square it is 2, in the cube 3, &c. If the co-efficient of  $a$  in any term be multiplied by its index, and the product divided by the number of terms to that place, the quotient will give the co-efficient of the next term.

Thus are we furnished with a general rule for raising the binomial  $a + b$  to any power, without the process of actual multiplication. For were we required to raise  $a + b$  to the eighth power, the rule just laid down shews us, that

The first term is .....  $a^8$

The second .....  $8a^7b$

The third .....  $\frac{8 \times 7}{2} a^6b^2 = 28a^6b^2$

The fourth .....  $\frac{28 \times 6}{3} a^5b^3 = 56a^5b^3$

The fifth .....  $\frac{56 \times 5}{4} a^4b^4 = 70a^4b^4$

The sixth .....  $\frac{70 \times 4}{5} a^3b^5 = 56a^3b^5$

The seventh .....  $\frac{56 \times 3}{6} a^2b^6 = 28a^2b^6$

The eighth .....  $\frac{28 \times 2}{7} ab^7 = 8ab^7$

The ninth .....  $= b^8$

When the number of terms is even in the resulting quantity, the co-efficients of the two middle terms are the same; and, in all cases, the co-efficients increase as far as the middle term, and then decrease precisely in the same manner, till we arrive at the last term. Guided by this law of the co-efficients, we need only calculate them as far as the middle term, and then set down the remaining ones in an inverted order.

Thus, in  $x - y$  } The first five co-efficients are } 1, 9, 36, 84, 126  
 } And the last five ..... } 126, 84, 36, 9, 1.

This rule, exhibited in its most general form of the *Newtonian Binomial Theorem*, is thus read:

Suppose we were required to raise the binomial  $a + b$  to any power denoted by  $n$ : From the principles already laid down,

The first term would be  $a^n$ .

The second.....  $na^{n-1}b$ .

The third.....  $\frac{n(n-1)}{2}a^{n-2}b^2$ .

The fourth.....  $\frac{n(n-1)(n-2)}{2.3}a^{n-3}b^3$ .

The fifth.....  $\frac{n(n-1)(n-2)(n-3)}{2.3.4}a^{n-4}b^4$ .

The last.....  $b^n$ .

Or,  $(a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{2}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{2.3}a^{n-3}b^3 + \frac{n(n-1)(n-2)(n-3)}{2.3.4}a^{n-4}b^4 + \&c. \dots + b^n$ .

By the same process,  $(a-b)^n = a^n - na^{n-1}b + \frac{n(n-1)}{2}a^{n-2}b^2$

$\frac{n(n-1)(n-2)}{2.3}a^{n-3}b^3 + \&c.$ ; the signs of the terms being

alternately + and -.

**BIQUADRATIC ROOT**, is the fourth root of any proposed quantity; thus 2 is the biquadratic, or fourth root, of 16. The biquadratic root of a number is found by extracting the square root of it, and then the square root of that root; which last result will be the root sought. Thus, the fourth root of 20736 is found as follows:

$$\begin{aligned}\sqrt{20736} &= 144, \text{ the square root,} \\ \sqrt{144} &= 12, \text{ the 4th root sought;}\end{aligned}$$

and so on for any other number.

**BIQUADRATIC EQUATION**, is an equation of the fourth degree, or in which the unknown quantity rises to the fourth power; thus,  $x^4 + ax^3 + bx^2 + cx + d = 0$ , is a biquadratic equation, in which  $a, b, c$ , and  $d$ , may be any numbers whatever, positive or negative, or any of them equal to zero or 0.

A biquadratic equation is the highest order of equation that admits of a general solution; all beyond this being resolvable only in particular cases. For the solution of equations of the fourth degree, different solutions have been proposed by several authors.

**BIQUINTE ASPECT** of the *Planets*, is when they are distant from each other  $144^\circ$ , or twice the fifth part of  $360^\circ$ .

**BIRCH**, *Bark of*, is used in Russia as we use tiles to cover houses; and among the Indians of America, it covers the slender ribs of their canoes. Birch leaves are of use in the dropsy, itch, &c.

**BIRDS**, in Heraldry, represent a contemplative or active life, and are emblems of expedition, liberty, readiness, and fear.

**BIRDS**. The skeleton or bony frame of birds is lighter than that of quadrupeds, and is calculated for the power of flight; the spine is immovable, the neck lengthened and flexible; the breast-bone very large, with a prominent keel down the middle, and formed for the attachment of strong muscles. The bones of the wings are analogous to those of the fore-legs in quadrupeds, but the termination is in three joints, of which the exterior one is very short. The legs are analogous to the hind-legs in quadrupeds, and terminate in general in four toes, three of which are commonly directed forwards, and one backwards; in some birds there are only two toes, in others, only three. All the bones in birds are much lighter than in quadrupeds.

The feathers with which birds are covered, resemble the hair of quadrupeds, being composed of a similar substance in a different form. Beneath the general plumage, the skin in birds is covered with a much finer feathery substance, called *down*. The throat, after passing down to a certain distance, dilates into a large bag, answering to the stomach in quadrupeds: it is called the *crop*, and its great use is to soften and prepare the food taken into it, for passing into another receptacle, called the *gizzard*. This powerful stomach consists of two strong muscles, lined and covered with a strong coat furrowed on the inside. In the birds of prey, or *accipitres*, this is wanting, the

stomach being allied to that of quadrupeds. In this receptacle, the food is ground, and reduced to a pulp. The lungs of birds differ from those of quadrupeds in not being loose in the breast, but fixed to the bones; they consist of a pair of large spongy bodies, covered with a membrane, which is pierced in several places, and communicates with large air-bags, dispersed about the cavities of the body. The eyes of birds are more or less convex in the different tribes; and in general, their sight is more acute than that of most other animals. Their ear, though internal, is constructed very nicely, on the same general plan as in quadrupeds. Their organs of motion are two wings and two legs; and they are destitute of external ears, lips, and many other parts which are important to quadrupeds.

Birds are produced from eggs, which vary in number, size, and colour, but are always covered with a hard shell, and for the most part deposited in an artificial nest, and hatched by the general warmth of the parent sitting upon them.

Linnaeus has divided this class into six orders:—1. *Accipitres*, hawks, &c.; 2. *Picæ*, pies, &c.; 3. *Passeres*, sparrows, &c.; 4. *Gallinæ*, poultry, &c.; 5. *Grallæ*, herons, &c.; 6. *Anseres*, geese, &c.

The orders of birds are these:—I. *Land Birds*.—1. *Rapacious birds* have the upper mandible hooked, and an angular projection on each side near the point, as the eagles, hawks, and owls. 2. *Pies*, have their bills sharp at the edge, somewhat compressed at the sides, and convex at the top, as the crows. 3. *Passerine birds*, have the bill conical and pointed, and the nostrils oval, open, and naked, as the sparrow and linnet. 4. *Gallinaceous birds*, have the upper mandible arched, and covering the lower one at the edge, and the nostrils arched over with a cartilaginous membrane, as the common poultry, turkeys, &c.

II. *Water Birds*.—5. *Waders*, have a roundish bill, a fleshy tongue, and the legs naked above the knees, as the herons, plovers, and snipes. 6. *Swimmers*, have their bills broad at the top, and covered with a soft skin; and the feet webbed, as ducks and geese.

**BIRDS, To Preserve**. The preserving of beautiful birds, with which some foreign countries abound, so as to retain their natural form and position, as well as the beauty of their colours and plumage, must be attended to with great care, lest they should be destroyed by insects, which has often been the case, to the great disappointment of the naturalist. After dissecting all the fleshy parts from the bones, and removing the entrails, eyes, brains, and tongue, the cavities and inside of the skin should be sprinkled with the following antiseptic powder.

|                                  |       |
|----------------------------------|-------|
| Muriate of mercury .....         | 2 oz. |
| Calcined nitrate of potass ..... | 2     |
| ———— sulphate of alumine .....   | 2     |
| Sulphur .....                    | 4     |
| Camphor .....                    | 2     |
| Pulverized black pepper .....    | 8     |
| ———— tobacco .....               | 8     |

Mix the whole together, and keep it in a glass vessel, stopped up very close. In Guiana, the number and variety of beautiful birds is so great, that several persons in the colony advantageously employ themselves in killing and preserving these animals for the cabinets of the naturalists in the different parts of Europe. The method of doing this, as related by Mr. Bancroft, is to put the bird which is to be preserved, in a proper vessel, and cover him with high wines, or the first distillation of rum. In this spirit he is suffered to remain for twenty-four or forty-eight hours, or longer, according to his size, till it has penetrated through every part of his body. When this is done, the bird is taken out, and his feathers, which are noways changed by this immersion, are placed smooth and regular. He is then put into a machine made for the purpose, among a number of others; and his head, feet, wings, tail, &c. are placed exactly agreeable to life. In this posture they are all placed in an oven moderately heated, where they are slowly dried, and will ever after retain their natural position, without danger of putrefaction.

*To make Pictures of Birds, by Means of their own Feathers*.—Get a thin board or panel of deal, or wainscot, well seasoned,

that it may not warp. Paste white paper over it, and let it dry. Take any bird you would represent, and draw its outline on the paper in the attitude you desire, and of the full size, adding what landscape, back ground, &c. you wish. This outline, so drawn, is afterwards to be filled up with the feathers from the bird, placing each feather in that part of the drawing corresponding to the part of the bird it was taken from. Cover now the representation with several coats of strong gum water, letting it dry between each coat till it is of the thickness of a shilling. When your ground is thus prepared, take the feathers off from the bird, beginning at the tail or points of the wings, as you must work towards the head. These feathers are prepared by cutting off all the downy part; and the larger feathers have the insides of their shafts pared off, to make them lie flat. To lay them on, use a pair of small pliers to hold them by; and moistening the gummed ground with water, place each feather in its natural and proper situation. Keep each feather down, by putting a small leaden weight upon it, till you have another prepared to lay on. Be careful not to let the gum come through the feathers, as it smears them, and, sticking to the bottoms of the weights, will be apt to pull the feathers off. When you have put on all the feathers, cut a piece of round paper, and colour it like the eye, which you may stick in its place; but the best way is to get eyes made of glass. The bill, legs, and feet, must be drawn and coloured from nature. When it is finished and adjusted to your mind, lay a sheet of paper upon it, and upon that a heavy weight to press it; which must remain till the whole is quite dry.

**BISECTION**, the division of a quantity into two equal parts.

**BISSEXTILE**, or **LEAP YEAR**, in Chronology, a year consisting of 366 days, happening once every four years, by reason of the addition of a day in the month of February, to recover the six hours which the sun spends in his course each year, beyond the 365 days ordinarily allowed for it. The day thus added is also called *bissextile*; Julius Cæsar having appointed it to be introduced, by reckoning the twenty-fourth of February twice; and as this day, in the old account, was the same as the sixth of the calends of March, which had been long celebrated among the Romans on account of the expulsion of Tarquin, it was called "*bis sextus calendas Martii*;" i.e. twice the 6th of the calends of March; and from hence we have derived the name *bissextile*.

By the statute *de anno bissextile*, 21 Henry III. to prevent misunderstandings, the intercalary day, and that next before it, are to be accounted as one day.

The astronomers concerned in reforming the calendar, by order of Pope Gregory XIII. in 1582, observing that the *bissextile* in four years, added forty-four minutes more than the sun spent in returning to the same point of the zodiac, and computing that these supernumerary minutes, in 133 years, would form a day; to prevent any changes being thus insensibly introduced into the seasons, directed, that in the course of 400 years, there should be three *bissextiles* retrenched; so that every centesimal year, which, according to the Julian account, is *bissextile* or leap year, is a common year in the Gregorian account, unless the number of centuries can be divided by four without a remainder. Thus 1600 and 2000 are *bissextile*; 1700, 1800, and 1900, are common. But with the exceptions of the above even centuries, any year which exactly divides by four is leap year; and when there is any remainder, it indicates the number of years since leap year.

The Gregorian computation was received in most foreign countries, ever since the reforming of the calendar; and by act of parliament, passed anno 1751, it commenced in all the dominions under the crown of Great Britain in the year following, ordering, that the natural day following the second of September, should be accounted the fourteenth; omitting the intermediate eleven days of the common calendar.

**BITTS**, a frame composed of two strong pieces of timber, fixed perpendicularly in the fore part of a ship, whereon to fasten the cables as she rides at anchor; in ships of war, there are usually two pair of cable bits, and when they are both used at once, the cable is said to be double bitted. There are several other smaller bits; as, the topsail sheet bits, paul bits, carrick bits, &c.

**BLACK**, an epithet applied to any thing opaque and porous, which imbibes the greater part of the light that falls on it, reflects little or none, and therefore exhibits no colour.

Bodies of a black colour are found more inflammable, because the rays of light falling on them are not reflected outwards, but enter the body, and are often reflected and refracted within it, till they are stifled and lost; and all other circumstances being alike, they are also found lighter than white bodies, being more porous.

A Prussian chemist, (a Mr. Salverte,) in making experiments to improve printers' ink, has discovered a process of producing from hempseed oil, a new species of black pigment, which, for brilliancy and intensity of colour, far exceeds any black known heretofore, and promises to render Prussian black as distinguished a colour as Prussian blue is at present. The inventor has, we understand, not only applied it to improve printers' ink, but also to other useful purposes, particularly as a superior and safe blacking for tanned leather.

The inflammability of black bodies, and their disposition to acquire heat beyond those of other colours, are easily evinced. Some appeal to the experiment of a white and black glove, worn in the same sun; the consequence will be, a very sensibly greater degree of heat in the one hand than in the other. The same thing appears from the phenomena of burning glasses, by which black bodies are always found to kindle soonest; thus a burning glass, too weak to have any visible effect upon white paper, will readily kindle the same paper when rubbed over with ink. Take a large tile, and having whited over one half of its superficies, and blacked the other, expose it to the sun; where having let it lie a convenient time, you will find, that whilst the whited part remains still cool, the black part has grown very hot. For farther satisfaction, leave on the surface of the tile a part retaining its native red, and exposing all to the sun, you will find the latter to have contracted a superior heat in comparison of the white part, but inferior to that of the black. So also on exposing two pieces of silk, one white and the other black, in the same window to the sun, the latter will be considerably heated, when the former has remained cool. Rooms hung with black are not only darker, but warmer than others. Cover the bulb of a thermometer with a black coating of Indian ink, and the mercury will rise several degrees.

**BLAGRAVE**, JOHN, an eminent mathematician, who flourished about the beginning of the seventeenth century.

**BLEACHING**, an art which has been cultivated from time immemorial, is divided into two branches; the bleaching of vegetable, and of animal substances. These being of different natures, require different processes for whitening them. Vegetables consist of oxygen, hydrogen, and carbon, of which the latter is in the greatest proportion; animal substances, besides these, contain a large quantity of azote, with phosphorus and sulphur. Hence,

*To Bleach Flax and Hemp*, which, if examined, will be found to consist of a thin bark, enveloping a green sap, then the fibres or filaments that are used in the making of linen, and within that the woody part. The fibrous part only is used in the making of cloth, and is separated from the other substances, by being first steeped in soft water, until the putrefactive fermentation takes place, with the succulent part, and is taken out of the water as soon as the wood breaks easily between the hands, while it is yet green, and before the whole of its sap is separated. Well water, brackish water, and that which flows over gypseous soil, must be avoided, else the putrefaction will be accelerated, and the texture of the fibres injured. It is thus that a small quantity of salt accelerates animal putrefaction, while a great deal tends to prevent it; and the portion of saline substances held in solution in the water, hastens the corruption of the filaments, which it blackens and spoils. This operation of watering the flax, is tedious and noxious; it destroys the fish in any stream that may be used, and the smell of the putrefying plants is offensive. Modern chemistry shortens this process, and performs it with less risk of injuring the flax, by the following process: If the stream of a solution of caustic alkali in water be introduced into a chamber about thirty feet square, in which the flax is suspended, it will produce the same effect as watering, in less time, with less expenses, and

less danger to the flax, which is frequently injured by being too long steeped. Nothing remains after the watering is completed, but the woody part, a hollow tube of compact flax. To separate these stalks, it must be kiln-dried to render it brittle, but too much heat must not be applied. It is next to be beaten or broken, either by manual labour with mallets on wooden anvils, as in the houses of correction, or by mills for the purpose. By this means the flax is divided into small fibres, and most of the wood reduced to small fragments, which are cleared away by scutching or threshing.

Hackling, the last process, is nothing more than combing the flax in small parcels at a time through a pile of polished sharp iron spikes, placed pretty close together, in a wooden board; the first hackle is coarse, the second finer, and the third finer again. The process of hackling divides the fibres of the flax from each other; it detaches the minute fragments of wood which escaped the scutching, and it separates the tow from the short coarse flax. The flax is now ready to be spun into thread or yarn, which is afterwards manufactured into cloth.

*To Bleach Linen Cloth.*—The linen, as it comes from the loom, is charged with the weaver's dressing, a paste of flour and water, to make it stretch more easily. To discharge this, the linen must be steeped 48 hours in water, till the extraneous substance is decomposed by fermentation. Some bleachers boil the linen in water; but improperly, for paste is not soluble in boiling water. When the linen is well washed and rinsed, after the last process, it is of a grayish white colour, the fibres of which it is composed are naturally very white. And to separate matter that discolours the linen, is the business of bleaching. This gray substance is of a resinous nature, insoluble in water, and from its intimate union with the very fibres of the flax, it is difficult of separation, even by substances that have a solvent power.

Alkaline leys, or solutions of alkali rendered caustic, have the property of dissolving resins, and are employed as menstrua for this purpose. Alone they are not sufficient to complete the process of bleaching. What appears a single fibre of flax in gray linen, is composed of a bundle of minute filaments, closely cemented by the resinous matter: therefore the potash first acts upon the resin of the external coating of the filaments; they are thus loosened or separated, and exposed to the further action of the air. The second boiling of potash opens a second layer, and thus successively layer by layer, till the whole is opened to the centre. If the alkaline solution were sufficiently strong to force its way at once to the centre, it would act upon the filaments, and destroy the texture of the cloth. Each filament, after the alkaline process, retains an impregnation of colouring matter, so intimately united as to resist its further action. This can only be removed by the gradual influence of the atmosphere, according to the old method of bleaching, or by the modern improvement of using oxygenated muriatic acid. To explain the principle by which this latter part of the process is effected, we must consider that the resin, which forms the colouring matter of unbleached linen, is composed chiefly of carbon and hydrogen: this is partly dissolved by the alkaline ley, and what remains becomes united to the oxygen of the atmosphere, flying off in the state of carbonic acid gas, or remaining as water. The old manner of bleaching was tedious, two or three months being necessary to give the cloth its pure whiteness. The simplicity of the process, however, and the scanty apparatus it requires, recommends it to people who make their own cloth, particularly in Scotland and Ireland.

The method of bleaching by the action of the atmospheric air is this:—After steeping the linen as mentioned above, to remove the weaver's dressing, the pieces of cloth are dried, and then submitted to the operation of bucking. For this purpose a ley is prepared, by dissolving a quantity of potash\* in soft water, to which some soap is added. This liquor is heated to about 100 degrees, and poured upon the linen. After the

cloth is well down in the ley, it is drawn off, heated a little higher, and again poured upon the linen. This operation is repeated at successive intervals, allowing the ley to remain longer each time, moderately increasing the heat for about six hours. The cloth is then left steeping for about four hours, when it is taken out, rinsed, and carried to the fields, where it is spread upon the grass, and secured by pins; water is sprinkled on it to keep it moist for some hours. After it has lain half a day, the watering is less frequent, and at night it is left to the dews. On the succeeding days it is watered three or four times, if the weather be dry, and then it remains on the field till the air seems to have little effect in whitening. It is then brought back to the coppers, and bucked again with a ley somewhat stronger than the last, rinsed, and again spread in the field. It is thus alternately bucked and watered from ten to fifteen times, according to the state of the weather, making the bucking stronger and stronger, till about the middle, and then weaker and weaker till towards the conclusion of the operation. It must now be soured, or steeped, in some acid liquor. The acid which has been usually employed for souring, is formed by the fermentation of bran and water; sour whey has sometimes been used. But sulphuric acid very much diluted, has been found more convenient, and not more injurious. The cloths are kept in the souring for about six days, if the liquor be formed of milk or bran, or a less time when sulphuric acid is used. They are then rubbed with soap, particularly the selvages, as these resist most the action of the air. It is again bucked, rinsed, watered, and exposed to the atmosphere, and these processes are successively repeated, till the linen has acquired its proper degree of whiteness.

To bleach by the oxygenated muriatic acid.—The oxygenated muriatic acid is only a combination of muriatic acid and oxygen. All vegetable colours are influenced by this acid, and whitened with more or less celerity; the colouring matter undergoes a real but slow combustion, which terminates by the formation of carbonic acid gas, that escapes into the atmosphere. In whatever manner the oxygenated muriatic acid is procured, the oxygen adheres to it very weakly, and upon this property depends the possibility of producing speedily, in manufactories, that action of bleaching which the atmosphere produces slowly. The method of bleaching by oxygenated muriatic acid was quickly and successively introduced into the manufactories of Manchester, Glasgow, Rouen, Valenciennes, and Courtray; and it has since been generally adopted in Great Britain, Ireland, France, and Germany. The advantages that result from this method, which accelerates the process of whitening cottons, linens, paper, &c. to a really surprising degree, in every season of the year, can be justly appreciated by commercial people only, who experience its beneficial effects in many ways, but particularly in the quick circulation of their capitals. To save the expense of first preparing the muriatic acid, you may mix with the oxide of manganese, muriate of soda, or common salt, and sulphuric acid diluted with water. The sulphuric acid acts upon the salt, and disengages from it the muriatic acid, which is oxygenated by the oxide of manganese. The proportions observed, when cotton is the article to be bleached, are, manganese, 30 parts; common salt, 80; sulphuric acid, 60; water, 120. For linen-cloth, the proportions are as follow: manganese, 60 parts; salt, 60; sulphuric acid, 50; water, 50. The better these substances are combined, the more easily will the acid gas be disengaged by the action of the sulphuric acid.

To ascertain the strength of the acid for bleaching, a solution of indigo in the sulphuric acid is employed. The colour of this is destroyed by the oxygenated muriatic acid, and, according to the quantity of it that can be discoloured by a given quantity of the liquor, its strength is determined. Cloth is prepared for immersion in oxygenated water, by first soaking it in a ley of weak potash, and rinsing it afterwards in water, to free it completely from the weaver's dressing, and the saliva of the spinners. In this country, machinery is employed for rinsing and beating; the apparatus must be arranged according to the objects to be bleached; the skeins of thread suspended in the tub destined for them, and the cloth rolled upon reels in the apparatus. When every thing is thus disposed, the tubs are filled with oxygenated muriatic acid, by

\* It is most economical to render it caustic for the purpose of bleaching. This is done by adding quicklime to the mild potash, the former having a stronger affinity for the carbonic acid than the latter. But care must be taken not to use the alkali too strong.

introducing a funnel, which descends to the bottom of the tub, in order to prevent the dispersion of the gas. The cloth is wound, or the frame-work on which the skeins are suspended is turned several times, until, by taking out a small quantity of the liquor from time to time, and trying it by the test of the solution of indigo, it is judged that it is sufficiently exhausted. The weakened liquor is then drawn off, and may be again employed for another saturation. Experience proves that the use of the oxygenated muriatic acid alone weakened the cloth, and various methods of preventing its noxious effects upon the health of the workmen were tried, till it was discovered that an addition of alkali to the liquor destroyed its suffocating effects, without injuring its bleaching powers. The process began then to be carried on in open vessels, and has since been continued in this manner. The bleacher is now able to work his pieces in the liquor, and to expose every part of them to its action, without risk or inconvenience.

Potash was at first used for this purpose; and although this advantage was unquestionably great, it was diminished by the heavy expense of the alkali, which was entirely lost. It was afterwards discovered that the oxymuriatic acid might be combined with the alkaline earths, as lime and barytes, and also with magnesia, by this means forming oxymuriates, which were soluble in water, and had the property of bleaching. The oxymuriate of lime is at present used in almost all the bleaching grounds. If the oxygenated acid be passed through lime water, it combines with the lime, and forms oxymuriate of lime; but as the water can only retain a small portion of lime, to cause a larger quantity of lime to combine with the oxymuriatic acid gas, the lime must be mechanically suspended in the water, into which the gas is made to pass, and agitated, so as to present fresh matter to the gas. By this means the oxymuriate of lime is dissolved in water, and used as a bleaching liquor preferable to the oxygenated muriatic acid and potash. At the great bleach-fields in Ireland, four leys of potash are applied alternately with four weeks' exposure on the grass, two immersions in the oxygenated muriate of lime, a ley of potash between the two, and the exposure of a week on the grass, between each ley and the immersions. During summer, two leys, and fifteen days' exposure, prepare cloth for the action of the oxygenated muriate; then three alternate leys, with immersions in the liquor, complete the bleaching, and nothing then will be necessary, but to wind the cloth through the sulphuric acid. The oxygenated muriatic acid gas may also be combined with lime in a dry state, or the water may be evaporated when it is employed for the formation of oxymuriates, which may then be very conveniently transported to any distance without injury to its deterative power.

The sulphuret of lime, or the combination of sulphur and lime, which are both cheap articles, answer the purposes of potash in bleaching; it is useful in some cases, in others it will not supersede the use of alkali. To prepare the sulphuret of lime for the purpose of bleaching: Take sulphur of brimstone, in fine powder, four pounds; lime, well slaked and sifted, twenty pounds; water, sixteen gallons; mix these well, and boil them for half an hour in an iron vessel, stirring them briskly. Soon after the agitation of boiling is over, the solution of the sulphuret of lime clears, and may be drawn off free from the insoluble matter, which rests upon the bottom of the boiler. The liquor, in this state, is of the colour of small-beer, but not so transparent. Sixteen gallons of fresh water are afterwards poured upon the insoluble dregs in the boiler, to separate the remaining sulphuret from them. When it clears, it is drawn off, and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which will reduce the liquor to a proper standard for steeping the cloth. Thus you have sixty gallons of liquor from four pounds of brimstone. When linen has been freed from the weaver's dressing, in the manner already described, it is to be steeped in the solution of sulphuret of lime (prepared as we have described) for about twelve or eighteen hours, then it is to be taken out and well washed. When dry, it is to be steeped in the oxymuriate of lime for about fourteen hours, and then washed and dried. To whiten the linen, this process is to be repeated during six alternate immersions in each liquor.

The rationale of these processes is the following: The oxy-

genated liquor supplies to the cloth the place of the atmospheric air, and this in greater abundance, and in a state which renders its action on the cloth more expeditious and more complete. By the union of the oxygen with the carbon of the cloth, carbonic acid is formed, and flies off; and the cloth becomes white.

To bleach by steam.—As the action of steam alone does not bleach, the concurrence of oxygen is necessary to aid the composition of the carbonic acid; for this acid requires for its formation, 28 parts of carbon, saturated with 72 of oxygen; but all the oxygen in the apparatus would not be sufficient to saturate the colouring matter burnt by the alkaline combustion, and converted into carbon; this deficiency is supplied by immersion in any oxygenated liquor whatever, and the dispersion of the elastic fluid thus formed is then facilitated by exposure on the grass. To bleach cloth in this manner, it must be immersed in a slight alkaline caustic liquor, and placed in a chamber constructed over a boiler, into which is put the alkaline ley which is to be raised into steam. After the fire has been lighted, and the cloth exposed to the action of the steam for a sufficient time, it is taken out, and immersed in the oxygenated muriate of lime, and afterwards exposed for two or three days on the grass. This operation, which is very expeditious, will be sufficient for cotton; but if linen cloth should still retain a yellow tint, a second alkaline caustic vapour bath, and two or three days on the grass, will be sufficient to give it the necessary degree of whiteness. For the use of private families, when the linen is dirtied by perspiration or grease, laundresses would do well to steep it for some time in clear water, made by mixing one quart of quicklime in ten gallons of water, letting the mixture stand twenty-four hours, and then using the clean water drawn from the lime. This whitens beautifully without injuring the cloth. The linen in many families is all washed in this manner. It is to be washed as usual, but will require much less soap to be used.

To bleach Cotton, requires not the same preparations as hemp and flax. The first operation is scouring it in a slight alkaline solution, or by exposure to steam. It is afterwards put in a basket, and rinsed in running water. The immersion of cotton in an alkaline ley, how well soever it may be rinsed, always leaves with it an earthy deposit. Cotton bears the action of acids better than hemp or flax; and time is even necessary before their action can be prejudicial to it. Hence, by pressing it down in a very weak solution of sulphuric acid, and afterwards renewing the acid by washing, lest remaining too long in it, the cotton should be destroyed; all the earthy matter is removed from it.

To bleach Wool.—Wool is a kind of hair, with which the bodies of some animals are covered, and is composed of filaments or tubes, filled with an oily or medullary substance. The sides of these tubes are perforated with a multitude of small pores, which communicate with a longitudinal tube. By chemical analysis, wool gives a great deal of oil, and carbonate of ammonia; caustic alkaline leys dissolve it entirely. It undergoes no change in boiling water; and scarcely alters when preserved in a place well aired; acids have very little action on it; and when exposed to a strong heat, it enters into fusion. The little action which acids have upon wool, and its unalterableness in water, even when aided by heat, render it necessary to have recourse to alkaline or saponaceous leys; but its solidity in these salts shews, that great prudence and caution must be employed in their use. In regard to acids, none have been hitherto used but sulphureous acid, obtained in the gaseous state by combustion.

In the preliminary operations to which wool is subjected, a little of its grease is left, to secure it from insects. Wool is often freed from the grease by farmers, who wish to sell it at a high price; but in the subsequent manipulations, it is greased before it is combed and spun, and as this fat matter attracts dust, it dirties and thickens the stuffs. The first kind of bleaching wool receives, frees it from these impurities. This operation, called scouring, is generally performed by means of an ammoniacal ley, formed of five measures of river water and one of stale urine; the wool is immersed for about twenty minutes in a bath of this mixture, heated to fifty-six degrees; it is then taken out, suffered to drain, and then rinsed in run-

ning water: this process softens the wool, and gives it the first degree of whiteness; it is thrice repeated, after which the wool may be employed. In some places, scouring is performed with water slightly impregnated with soap; and indeed, for valuable articles, this is the preferable process, but it is expensive for articles of less value.

Fulling the cloth adds still to the whiteness; and, if an increased degree be necessary, it may be procured by the action of the sulphureous acid; or of the fumes of sulphur in a state of combustion, or the vapour of that acid condensed and combined with water.

Sulphuring is performed in an arched chamber, constructed in such a manner, that the articles exposed to the action of the sulphur can be suspended. The chamber being filled, a certain quantity of sulphur is placed in it in a state of combustion, in flat dishes, the entrance is shut, and all the interstices around the door stopped, to prevent the access of the atmospheric air. The acid, generated by the combustion of the sulphur, penetrates the stuffs, attacks and destroys the colouring matter, and effects the bleaching. The stuffs are left in the stoves from six to twenty-four hours afterwards. They are then taken out, and passed through a slight washing with soap, to remove the roughness they have acquired by the action of the acid, and to give them the necessary softness. But then this process is imperfect. At first, the acid of the sulphur acts only on the surfaces, and does not penetrate. This aerial immersion is not sufficient; the gas cannot introduce itself to a sufficient depth into the stuffs, and the superficies only is whitened.

A superior method has been invented, which is, by making use of sulphureous acid; which is generated by the imperfect combustion of sulphur, and differs from the sulphuric acid, (oil of vitriol,) by containing less of the acidifying principle. It is the mean between sulphur and the sulphuric. Sulphureous acid gas unites easily with water, and in this combination is employed for bleaching wool or silk. The sulphureous acid in this liquid state, may be prepared by passing it through water in an apparatus nearly similar to that used for preparing oxygenated muriatic acid. The cheapest method of obtaining it, is to decompose sulphuric acid by the mixture of some combustible capable of taking from it parts of its oxygen. In experimental chemistry, it is obtained by means of metallic substances with great purity, and particularly by mercury; but for bleaching, and where great economy is required, we would recommend the most common substances, and the following process. Take chopped straw, or saw-dust, and introduce it into a mattress; pour over it sulphuric acid, applying at the same time heat, and there will be disengaged sulphureous acid gas, (vapour of sulphur,) which may be combined with water in the apparatus. The pieces are rolled upon reels, and drawn through the sulphureous acid, by turning them, until the whiteness is sufficiently bright. They are then taken out, and drained on a bench covered with cloth, lest they should be stained by the decomposition of the wood and the sulphureous acid. They are next washed in river water, and Spanish white is employed, if necessary. This operation is performed by passing the pieces through a tub of clear water, in which eight pounds of Spanish white have been dissolved. To obtain a fine whiteness, the stuffs are twice sulphured. This process is completed in one immersion, and a reeling of two or three hours.

To azure or blue the cloth, you throw, into the Spanish white liquor, a solution of one part of Prussian blue to 400 parts of water; shake the cloth in the liquid, and reel it rapidly. Then, by a slight washing with soap, to give softness and pliability to the stuffs, the operation is terminated. The final operations of drying, stretching, pressing, &c. have all been illustrated in what has been said of dyeing and bleaching linen; for the directions vary so little in both, that it would be but a repetition to detail here what the reader is already acquainted with.

To bleach Silk.—Silk is a semi-transparent matter, spun by a caterpillar, and formed of a substance contained in its body, which becomes hard in the air. The filaments, prepared by the silk-worm, are rolled up in a ball, and in this state it is covered with a yellow varnish, that destroys its brilliancy, and renders it tough. By chemical analysis, silk gives carbo-

nate of ammonia and oil; boiling water produces no effect upon it; alcohol makes it experience no change, but concentrated alkaline leys attack and dissolve it. To give splendour to silk, it must be freed from its varnish. This covering is soluble in alkaline leys. Silk is usually scoured by soap, when it loses one-fourth of its weight. The matter disengaged has a fetid smell, and if the silk be not rinsed in plenty of water putrid fermentation takes place. Even the least soap injures the whiteness of the silk. This is proved by the fact, that the splendour of the Chinese silks is brighter than that of the European; and the Chinese employ no soap in their operations. A slightly alkaline ley will dissolve the varnish of the silk without using soap; and this has also been effected by the action of boiling water at a very high temperature.

The following method has been used very successfully in France. Take a very weak solution of caustic soda, and fill with it the boiler of the apparatus for bleaching with steam. Charge the frames with skeins of raw silk, place them in the apparatus until it is full; then close the door, and make the solution boil. Having continued the ebullition for twelve hours, slacken the fire, and open the door of the apparatus. The heat of the steam, which is always above 250 degrees, will have freed the silk from the gum, and scoured it. Wash the skeins in warm water, wring them, place them again on the frame in the apparatus, and make the whole boil a second time. Wash them now several times in water, and immerse them in soapy water to give them softness. But the whiteness which silk acquires by these operations, is carried to a higher degree of splendour by exposing the material to the action of sulphureous acid gas, in a close chamber, or by immersing it in sulphureous acid, as we have explained for whitening wool.

To bleach Prints, and printed Books.—The new mode of bleaching has been applied to the whitening of books and prints that have been soiled by smoke and time, and therefore it will be proper that we here explain this process. To whiten an engraving, immerse it in oxygenated muriatic acid, letting the article remain in it a longer or shorter space of time, according to the strength of the liquid. To whiten the paper of a bound book, all the leaves must be moistened by the acid, and therefore care must be taken to open the book, and making the boards rest on the edge of the vessel, so that the paper alone shall be dipped in the liquid: the leaves must be separated from each other, to be equally moistened on both sides. In the same proportion as the liquor assumes a yellow tint, the paper becomes white. In about three hours, the book must be taken from the acid liquor, and the leaves plunged into pure water, with the same care and precaution as recommended in regard to the acid liquor, so that the water touch only the two surfaces of each leaf. The water must be renewed every hour, to extract the remaining acid, and dissipate the unpleasant smell. By this process, there is, however, some danger that the pages may not be all equally white, either because the leaves have not been sufficiently separated, or because the liquid has had more action on the exterior margins than those near the binding. The best way is to destroy the binding, and each leaf will thereby receive an equal and perfect immersion; this second process is thus described by Chaptal.

“They begin,” says he, “by unsewing the book, and separating it into leaves, which they place in cases formed in a leaden tub, with very thin slips of wood, or glass, so that the leaves, when laid flat, are separated from each other by intervals scarcely sensible. The acid is then poured in, making it fall on the sides of the tub, in order that the leaves may not be deranged by its motion. When the workman judges, by the whiteness of the paper, that it has been sufficiently acted upon by the acid, it is drawn off by a cock at the bottom of the tub, and its place is supplied by clear fresh water, which weakens and carries off the remains of the acid, as well as the strong smell. The leaves are then to be dried, and after being pressed, may be again bound up.

“The leaves may be placed also vertically in the tub: and this position seems to possess some advantage, as they will be less liable to be torn. With this view I constructed a wooden frame, which I adjusted to the proper height, according to the size of the leaves which I wished to whiten. This frame supported very thin slips of wood, leaving only the space of half a

line between them. I placed two leaves in each of these intervals, and kept them fixed in their place by two small wooden wedges, which I pushed in between the slips. When the paper was whitened, I lifted up the frame with leaves, and plunged them to remove the remains of the acid, as well as the smell; this process I prefer to the other.

"By this operation books are not only cleaned, but the paper acquires a degree of whiteness superior to what it possessed when first made. The use of this acid is attended also with the valuable advantage of destroying ink spots. This liquor has no action upon spots of oil or animal grease; but it has been long known that a weak solution of potash will effectually remove stains of that kind.

"When I had to repair prints so torn that they exhibited only scraps pasted upon other paper, I was afraid of losing these fragments in the liquid, because the paste became dissolved. In such cases I enclosed the prints in a cylindric glass vessel, which I inverted on the water in which I had put the mixture proper for extricating the oxygenated muriatic acid gas. This vapour, by filling the whole inside of the jar, acted upon the print; extracted the grease as well as ink spots; and the fragments remained pasted to the paper."

To prepare Oxygenated Muriatic Acid by an easy Method.—To oxygenate the muriatic acid, dilute it, and mix it in a very strong glass with manganese, so that the mixture may not occupy the whole contents of the glass. Air bubbles are formed on the surface of the liquor; the empty space becomes filled with a greenish vapour; and at the end of some hours the acid may be farther diluted with water, and then used. It will have an acid taste, because the whole has not been saturated with oxygen; but it will possess the qualities of the oxygenated muriatic acid. This process may be adopted when there is not time to set up an apparatus for distilling, to procure the oxygenated acid.

To bleach Paper.—The oxygenated muriatic acid has also been applied to bleach paper, being more expeditious. If we were to bleach old printed papers, to be worked up again, we must boil them for an instant in a solution of soda, rendered caustic by potash. Then steep them in soap-water, and then wash them, after which the whole may be reduced to a pulp by the paper-mill.

To bleach old written papers to be worked up again, we steep them in a cold solution of sulphuric acid in water, after which we wash them before they are taken to the mill. The acidulated water will be the more effectual if it be heated.

To bleach printed papers without destroying the texture of the leaves, we steep the leaves in a caustic solution of soda, and afterwards in one of soap. Then we arrange the sheets alternately between cloths, just as paper-makers dispose their sheets of paper when delivered from the form. The leaves must then be put in a press, and they will become whiter, unless they have been stained with printers' ink or size. If one operation should not completely effect the whitening of the leaves, you must repeat the process till it is effectual.

To bleach coloured rags to make white paper, we macerate the rags—then put them into a solution of caustic alkali, and next into the oxygenated muriatic acid;—lastly, they are to be steeped in diluted sulphuric acid.—These processes of bleaching have been classed under one general title, though the manufacture of paper has not been treated in conjunction with them.

To remove Ink Stains.—Apply to the stain muriatic acid diluted in six times its weight in water, and after a minute or two wash it off; the application should be repeated as often as may be found necessary. The vegetable acids equally effectual are attended with less risk. A solution of the oxalic, citric, (acid of lemons,) or tartareous acids, in water, may be applied to the most delicate fabrics without danger or injury; and the same solutions will discharge writing, but not printing ink. They may be therefore employed in cleaning books defaced by writing on the margin. Lemon, and sorrel juice, will remove ink stains, though not so easily as the concrete acid of lemons or citric acid.

To remove Iron Stains.—Ink stains, on the application of soap, are changed into iron stains. But the real iron stains are occasioned by the cloth coming in contact with iron, or its

oxyde. Both may be removed by diluted muriatic acid, or by the acid of lemons. When suffered to remain long on cloth, they are taken out with difficulty, because the iron, by repeated moistening with water, and exposure to the air, acquires such an addition of oxygen, as renders it insoluble in acids; yet these spots may be discharged, by applying first a solution of an alkaline sulphuret, which must be well washed from the cloth, and afterwards a liquid acid. The sulphuret, in this case, extracts part of the oxygen from the iron, and renders it soluble in diluted acids.

To remove the stains of fruit and wine, prepare a watery solution of the oxygenated muriatic acid, or oxygenated muriate of potash or lime, to which a little sulphuric acid has been added. Steep the stained spot in one of these solutions till it is discharged; the solution can only be applied to white goods, for the uncombined oxygenated acid discharges printed and dyed colours. The oxygenate acid is easily applied by persons who have not the apparatus for saturating water with the gas, thus:—Put a table-spoonful of muriatic acid (spirit of salt) into a teacup, and add to it about a tea-spoonful of powdered manganese; set this cup in a larger one filled with hot water; moisten the stained spot with water, expose it to the fumes which arise from the teacup, and if the exposure be continued a sufficient length of time, the stain will disappear entirely.

To remove spots of grease from cloth, take a diluted solution of potash, which must be cautiously applied, to prevent injury to the cloth. Stains of white wax, from wax candles dropping upon the cloths, are removed by spirits of turpentine, or sulphuric ether, which will also take out the marks of white paint.

To take spots of grease out of books, prints, or paper, warm the stained paper gently, and take out as much of the stain as possible by means of blotting paper; then dip a small brush in essential oil of turpentine, heated almost to boiling, (when cold, it acts weakly,) and draw it gently over both sides of the paper, which must be carefully kept warm. Repeat this operation as often as the spot imbibed by the paper, or its thickness, may render necessary. When the greasy substance has been removed, the paper may be restored to its former whiteness by the following method. Dip another brush in highly rectified spirit of wine, and draw it over the place which was stained, and particularly round the edges, to remove the border that would still present a stain. By employing these means with caution, the spot will disappear, and the paper will resume its original whiteness. Should the process be employed on a part written with common ink, or printed with printers' ink, it will experience no alteration whatever.

BLOCK MACHINERY. The machinery for manufacturing ship's blocks in the royal dockyard at Portsmouth, invented by Brunel, and adjusted in all its parts by the elaborate and ingenious calculations of Dr. Gregory, of the Royal Military Academy, Woolwich, who gives the following account of this apparatus, in vol. 11. of his *Mechanics*, is greatly and deservedly celebrated:

The machines devoted to this purpose have been separated into four classes. 1. The sawing machine for converting the large timber into proper dimensions for the small machines to operate upon. 2. Those machines which are employed in forming the sheaves. 3. Those which form the iron pins for the blocks. 4. Those by which the shells of the blocks are manufactured. They are all worked by means of two steam-engines, each of thirty-horse power. Either of these can be applied indifferently to work the chain pumps, or for turning the wood-mill; and their power is transmitted by a train of wheel-work, to a horizontal shaft, extending along the centre of the middle building, very near its roof. Upon this are a number of wheels and drums, which, by endless ropes and straps, communicate motion to the several subordinate machines.

The order of the processes is this. The elm trees are first cut into short lengths, proper to form the various sizes of blocks, by two large sawing machines, one a *reciprocating*, the other a *circular* saw. These lengths of the trees are next cut into squares, and ripped or split up into proper sizes by four sawing benches with circular saws, and one very large reciprocating saw, which is employed for cutting up the pieces for very large blocks.

The scantlings, thus prepared for the blocks, are perforated in three boring machines, with a hole through each to contain the centre pin for the sheaves of the block, and as many other holes in a direction perpendicular to the former, as the number of sheaves it is to have; these holes being intended as the commencement of the several mortises to contain the sheaves.

The blocks are next mortised in three mortising engines, which elongate the holes abovementioned to their proper dimensions. Here the motion of the sliding frame for the chisels, is communicated to it by means of a long working beam or lever, extending the whole length of the frame at the top of it. At one end it is united by a connecting rod with the chisel frame; and at the other it is fixed to an axis, which is supported by the framing, and which forms its centre of motion. A connecting rod is joined to it in the middle of the beam; the lower end of which is worked by a crank, formed in the middle of the main axis, which is situated in a direction perpendicular to that which we have described, and is supported in the framing. It is provided with a cone for casting off the movement. The engine with the beam acts with surprising rapidity, making upwards of 400 strokes per minute, at every one of which it cuts out a chip from each mortise as thick as pasteboard. Its movement is, indeed, so rapid, that the chisels cannot be distinctly seen when it is at work; so that the mortises seem to lengthen, and chips to fall out, without any evident cause.

The angles of the blocks are next cut off by three circular saws, as preparatory to reducing them to the elliptical figure.

The outside surfaces of the block are then formed to their true figure by three shaping-engines, each of which forms every part of ten blocks simultaneously. The scores, or grooves, round the block are next formed, to receive the rope or strap by which they are suspended; this is effected by two scoring-engines. Then the blocks are trimmed by manual labour, to smooth and polish them.

In order to make the sheaves, the first process is cutting pieces or flakes off the end of the trees of *lignum vitæ*, of a suitable thickness to form the sheaves. This is accomplished by a reciprocating and two circular saws. These flakes are made circular, and the centres pierced in two rounding and centering machines, or trepan saw.

A hole is next excavated in the centre of each sheave, to inlay the coak or piece of bell metal, which is fitted into the centre of each sheave, to form a socket for the centre pin. The centre holes through the coaks are next broached out to a true cylinder in three broaching-machines.

The last process is turning the faces and edges of the sheaves to a flat surface, in three facing lathes, which also form the grooves round the edges for them, for the rope which encompasses them when in the block. There are also two machines for making *dead eyes*, which are both ingenious and complete. The whole number of machines is thirty-seven.

Blocks are used for various purposes in a ship, either to increase the mechanical power of the rope, or to arrange the ends of them in certain places on the deck, and they may be readily found when wanted; they are consequently of various sizes and power, and obtain various names, according to their form or situation, thus:

A *Single Block*, contains only one sheave or wheel. A *Double Block*, has two sheaves. A *Long Tackle Block*, has two sheaves, one below the other. A *Snatch Block*, is a single block with an opening on one side, in which the bite of a rope may be laid instead of reeving the end through, which, in some circumstances, would be very inconvenient. The *Spring Block*, an invention of Hopkinson, of Philadelphia, calculated to assist a vessel in sailing, and particularly intended by him to be applied to the sheets and the dead-eyes; it is composed of a common block or dead-eye, attached to a spiral spring of well tempered steel, within the cavity of which is a chain of suitable strength, called a check-chain; when the spring is not in action, this chain is slack; but, when the spring is extended by the force of the wind as far as it may be without injury, the check-chain begins to bear, and prevents its farther extension. *Top Block*, is a large single block with an iron strop and hook, by which it is hung to an eye-bolt in the cap, and is used to sway up or lower down the topmasts. *Jear Blocks*, are twofold or threefold blocks, applied to hoist or lower the main and fore

yards. *Viol Block* or *Voyal Block*, is a large block through which the voyal or messenger passes when the anchor is weighed by the fore or jear capstan. *Clue-garnet* and *Clue-line Blocks*, are distinguished from others by having shoulders upon their upper parts, through which the strop is laid, and is applied to draw up the clues or lower corners of the square sails to their respective yards. *Cat Block*, is a two or three fold block, with an iron strop and large hook to it, and is employed to draw the anchor up to the cathead.

Every block is composed of three, and generally four, parts: 1. The shell, or outside wooden part. 2. The sheave, or wheel, on which the rope runs. 3. The pin, or axle, on which the sheave turns. 4. The strop, or part by which the block is made fast to any particular station, and is usually made either of rope or of iron. *Iron-stropped Blocks*, frequently have the hook working in a swivel in order to turn it, that the several parts of the rope of which the tackle is composed, may not be twisted round each other, which would greatly diminish the mechanical power.

*Block and Block*, is the situation of a tackle when the blocks are drawn close together, so that the mechanical power becomes destroyed till the tackle is again overhauled by drawing the blocks asunder.

BLONDEL, FRANCIS, a celebrated French mathematician and military engineer, was born in Picardy in 1617, and died in Paris in 1686. He was author of two distinct works on architecture, and another on fortification; besides which, he published "A Course of Mathematics," "The Art of throwing Bombs," and several ingenious pieces in the *Memoires of the French Academy of Sciences*, particularly in the year 1666.

BLOOD, *Circulation of the*. About the year 1600 Mr. Harvey, an English physician, discovered the process (if we may so call it) of the circulation of the blood; to form a distinct notion of which, it will be necessary to describe the structure of the arteries, veins, and nerves; and principally the cavities of the heart, by means of which the blood is propelled through the body. To these we now proceed:—

The arteries are blood-vessels consisting of a close texture of strong elastic fibres, woven in various webs, laid in different directions, and interspersed with an infinity of delicate nerves, veins, and minuter arteries. They are divided and subdivided into numberless branches and ramifications, that become smaller and smaller as they recede from the heart, until at last their extremities are found much more slender than the hairs of our heads, (and are therefore called capillary arteries,) which either unite in continued pipes with the beginnings of the veins, or terminate in small receptacles, from which the veins derive their origin. The arteries have no valves, but only have their trunks spring from the heart: they throb and beat perpetually whilst life remains; their extremities differing in the thickness of their coats and some other particulars, according to the nature of the part which they pervade. All the arteries in the lungs (except the small ones that convey nourishment to them) are derived from the great pulmonary artery, which issues from the right ventricle of the heart. And all the arteries in the rest of the body proceed from the aorta, (which obtained this name, because the ancients thought it contained air only,) whose trunk springs from the left ventricle of the heart.

The veins resemble the arteries in their figure and distribution; but their cavities are larger, and their branches, perhaps, more numerous. Their coats are much weaker and more slender than those of the arteries. They are furnished with several valves, contrived in such a manner as to permit the blood to pass freely from the smaller into the larger branches, but to stop its retrogression. They neither throb nor beat. Their beginnings form continued pipes with the extremities of the arteries, or arise from some gland or receptacle where the arteries terminate. All the veins in the lungs, from their capillary beginnings growing still larger, unite at last, and discharge their blood into the left auricle of the heart: and all those in the rest of the body empty themselves in like manner into the *vena cava*, which opens into the right auricle of the heart.

The nerves deduce their origin from the brain, or its appendages, in several pairs, of a cylindric form, (like so many skeins of thread with their respective sheaths,) which in their progress

decrease by endless divisions and subdivisions, until at last they spread themselves into a texture of filaments so slender, and so closely interwoven with each other over the whole body, that the point of a needle can hardly be put upon any part of it, without touching the delicate branch of some nerve.

It has been found by many trials, that when an artery is laid bare, and a ligature made upon it, if it be opened with a lancet between the ligature and the heart, the blood will rush out with great violence; and a rapid, jerking stream will continue, (if it be not stopped by art,) until, through loss of blood, the animal faints or dies. But if the same artery be opened between the ligature and extremities, a few drops only will ooze out from the wounded coats. On the other hand, when a vein is laid bare, and a ligature made upon it, if it be opened between the ligature and the extremities, the blood will gush out, as we see in common venesection. But if the same vein be opened between the binding and the heart, no blood will appear. From these experiments it is obvious to the slightest attention, that the blood flows from the heart, through the arteries, to the extreme parts of the body; and returns again through the veins to the heart.

For the regular performance and continuation of this motion of the blood through all the different parts of the body, the heart, which is the *primum mobile*, giving the first impulse, is furnished with four distinct muscular cavities, that is, with an auricle and a ventricle on the right side, and an auricle and ventricle on the left. Through these cavities, curiously adapted to their respective offices, the blood circulates in the following order:—it is received from the veins, first into the right auricle, which, contracting itself, pushes the blood into the right ventricle, at that instant dilated. The moment this ventricle is filled, it contracts itself with great force, and impels the blood into the pulmonary artery, which, passing through the lungs, and returning by the pulmonary veins, is received into the left auricle of the heart, and from thence it is pushed into the left ventricle; which, being thus filled, contracts itself, and drives the blood with great rapidity to all the parts of the body, and from them it returns again through the veins into the right auricle of the heart, as before.

It is very remarkable, that we have here a double circulation: one from the right ventricle, through the lungs, to the left auricle of the heart, in order to convert the chyle into blood, and finally prepare it for the nourishment of the animal; the other, from the left ventricle, through the whole body, to the right auricle of the heart, which serves to apply that nourishment to every part, besides various other purposes.

But to proceed:—Of these four muscular cavities, the two auricles are contracted at the same instant, while the two ventricles are dilated; the ventricles, in their turn, are contracting themselves at the same instant that the auricles are dilating. The arteries, in like manner, beat in alternate time with the ventricles of the heart.

The nerves, as well as the veins and arteries, act their part in this rotation of the blood; for if the eighth pair of nerves which proceeds from the brain to the heart be bound up, the motion of the heart immediately languishes, and soon ceases entirely. Thus we have a species of perpetual motion, which none but a Being of infinite wisdom and power could produce; yet whose continuation requires the constant aid of the same hand that first gave it existence. The brain transmits animal spirits to the heart, to give it a vigorous contraction. The heart, at the same time, pushes the blood into the brain, to supply it with new spirits; by which means the head and the heart give continual mutual support to each other. But this is not all; the action of the heart sends the blood and other vital humours over the whole body by the arteries, and distributes nourishment and vigour to every part, (while perhaps the animal spirits, from the extremities of the nerves, return again into the blood,) and the whole reflux mass is conveyed back through the veins into the heart, which enables it, without intermission, to persist in rolling this tide of life.

But here it must not be supposed, that the arteries pass on to the extremities of the limbs, before they communicate with the returning veins; for upon this supposition, after an amputation has been performed, whatever blood might be brought to the stump by the arteries, it is certain, none of it could be

carried back again to the heart; because the intercourse between the heart and the limbs would, in this case, be entirely cut off. But the all-wise Author of our being has provided for this exigency, by forming a great number of less branches from the larger arteries, which constantly communicate with corresponding branches of the returning veins. And hence, it is easy to conceive how the circulation is carried on after amputation has been performed.

**BLOWPIPE, ALCOHOL.**—1. Copper ball, containing alcohol. 2. Tube to convey alcohol to, 3. A lamp, which keeps it boiling. 4. Jet of alcohol inflamed by the lamp. 5. Glass tube, bent by the flame.

This is really an useful instrument. The alcohol in the copper ball is boiled by the flame of the lamp placed underneath; this causes expansion, and the escape of the gas in a jet passing through the flame; and from its highly inflammable nature, a stream of intense heat is thus made to play upon any substance you wish to bring into fusion. There are many different kinds of blowpipes; but none more powerful than the Oxy-hydrogen blowpipe of Mr. Gurney.

A flux for the blowpipe, that will cause the particle of mineral, under examination, to run into a metallic globule upon the charcoal, as soon as any other now in use, may be thus made:—Take of borax 1 ounce, nitre 2 drachms, pounded flint glass 2 drachms, and calcined horse's hoof half an ounce; these are all to be fused together in a crucible, taking care to add the horse's hoof last, and stirring it well in with an iron spatula; when it is quite fluid, pour it into cold water, which will render it brittle, and thereby it may be easily pulverized. It is to be kept in well-closed phials, free from moisture, and the expense will be very trifling, compared with its great importance.

Hydrogen gas mixed with oxygen, furnishes an explosive compound of prodigious force. These gases, mixed in a bladder, in the exact proportion to form water, and afterwards condensed, and allowed to issue by a jet, which may be inflamed, and used in the operations of the blowpipe, under the title of Oxy-hydrogen Gas Blowpipe, of which the following figure represents Mr. Gurney's instrument.

Mr. Gurney has proved, by experiment, that the flame from a mixture of oxygen and hydrogen gases will pass through successive layers of the smallest wire gauze;—through the

smallest apertures made in lead;—through plaster of Paris; pipe clay; the natural pores of cane; and those of Honduras mahogany. He has shewn, that no means have hitherto been adopted, capable of preventing the explosion of these mixed gases under certain circumstances; and has thus shewn the great danger attending the use of instruments. One of the principal advantages attending the well constructed blowpipe before us, consists, it is said, in its being *perfectly safe*; and every apprehension of danger being thus removed from the mind of the operator, he is enabled to give his undivided attention to the changes and effects taking place in the substance operated upon; and whilst coolly examining, and noting every circumstance, a slight pressure with one hand is all that is requisite to produce a degree of heat of any required intensity. In this machine, A is the safety chamber, B a water trough, through which the gas is made to pass from the gasometer D, by the stop-cock C, through a tube which reaches to the bottom of the water trough; E is a cork, fitted into the neck of the same, from which it is thrown out, should an explosion take place on the surface of the water; F is a gauge, to indicate the necessary height of the column of water in the trough; G is a transferring bladder, which is made to screw and unscrew to and from the stop-cock H, and for supplying the gasometer with the gases, which may be charged and recharged at pleasure by an assistant during its action, so as to keep up the most intense flame, for any length of time. A valve is placed between the gasometer and the transferring bladder, which prevents the return of the gas; I, I is the light wooden, or stiff pasteboard cap, which combines sufficient strength, with great lightness, so that in case an explosion of the gasometer should happen, it is merely thrown a short height into the air, by the force rupturing the strings which connect the cap to the press board. To these strings are attached small wires, which pass through the table of the instrument, as at L into the press board below, where they are secured; this press board is kept in an horizontal position by the stand, so that when the requisite pressure is given to it, the cap I, I is brought to bear equally on the gasometer D. The gasometer bladder, (or silk bag,) is tied to a piece of bladder, which screws into a long tube, laid into and across the table, which permits it to be unscrewed at pleasure from the body of the instrument, and immersed in warm water, when it requires softening; affording also the means of fixing on another bladder, if any accident renders it necessary. The stop-cock of the charging bladder G is fixed at one end of the tube just described, and the stop-cock of the water trough on the other.

To operate with the instrument, pressure by the hand is applied to the press board, which draws down the cap I, I on the gasometer D, and forces the gas which it contains through the stop-cock C, through the water tube and safety chamber A, to the jet at the end, where it is burned. When the pressure on the press board is too slight, or when the hand is taken off, the flame returns into the safety chamber, and is extinguished. When it is required to suspend the operation, the hand need only be taken off from the pressing board, the water in the trough acts as a self-acting valve, in preventing the escape of the gas from the instrument, and saves the necessity of turning

the stop-cock. A silk tube is attached to the end of the tube before described in the water trough, which prevents the splashing of the water, sometimes occasioned by unskilful management.

The ease and confidence with which this instrument may be used, and its wonderful power in reducing, almost instantaneously, the hardest and most refractory substances, will enable the chemist, the philosopher, and the artisan, to avail themselves of the astonishing powers of an oxy-hydrogen blowpipe, not only without any personal risk, but even without the apprehension of any. Gun flints are instantly fused by this instrument, and formed into a transparent glass; (but owing to the rapid expansion of the water of crystallization, which causes the flints to break and fly off in pieces, it is recommended that they be first deprived of it by calcination.) China melts into a perfect crystal. All kinds of porcelain are readily fused; previously assuming a beautiful white vitrified appearance. Rock crystal is quickly melted, giving out a beautiful light. Emerald, sapphire, topaz, beryl, and all the other precious stones, melt before it into transparent glassy substances. Barytes, strontia, lime, alumina, exhibit very striking and beautiful phenomena. Magnesia fuses into hard granular particles, that will scratch glass. The metals (even platina) are *all* quickly fused by it. A steel file, brought into contact with the flame, fuses and scintillates in the most beautiful manner, forming a magnificent firework. In a word, all descriptions of stones, slates, and minerals, are melted, sublimed, or volatilized, by its all-subduing power.

**BLOWING of Glass.** See GLASS.

**BLOWING Machines.** See FURNACE.

**BLUE**, one of the seven primitive colours of the rays of light, into which they are divided when refracted through a glass prism. See COLOURS and PRISM. The blue colour of the sky is a remarkable phenomenon, which has been variously accounted for by different philosophers. La Hire, after Leonardo de Vinci, attributed it to the effect which is produced by viewing a dark body through a white transparent one, which he observes always gives the sensation of blueness; and thus the sky being itself totally devoid of light, when viewed through the air illuminated and whitened by the sun, appears of that blue colour so constantly observed. According to Newton, however, the phenomenon is to be accounted for on other principles. He observes, that all the vapours, when they begin to condense and coalesce into natural particles, become first of such a bigness as to reflect the azure rays, before they can constitute clouds of other colours. Bouguer ascribes this blueness of the sky to the constitution of the air itself, being of such a nature that the fainter coloured rays are incapable of making their way through any very considerable portion of it. We conceive, that this blue colour is occasioned by the vapours mixed with air, and which have the property of reflecting the blue rays more copiously than any others.

**BOATS**, small open vessels, conducted on the water by rowing or sailing, are distinguished by different names, according to their size and construction. The long boat, usually the largest boat that accompanies a ship, is generally furnished with a mast and sails, and may be armed and equipped for cruising short distances; her principal employ, however, is, to bring heavy stores or provisions on board, and also to go up small rivers to fetch water, wood, &c. The launch, a boat which has greatly superseded the use of the long boat, particularly by merchant ships in the Mediterranean, is longer, more flat-bottomed, and by rowing a greater number of oars, is better adapted for going into narrow and shallow rivers. The barge, a long, narrow, and light boat, employed to carry the principal officers, as admirals and captains of ships of war, and is very unfit for sea. A pinnace resembles a barge, but is smaller, never rowing more than eight oars, whereas a barge never rows less than ten; the pinnace is for the accommodation of the lieutenants, &c. The cutters of a ship are broader, deeper, and shorter than the barge or pinnace, are fitter for sailing, and commonly employed in carrying light stores, passengers, &c. to and from the ships; they are built differently from the former boats; the lower edge of every plank overlaying the upper edge of the plank below it, which is called clinch work. They generally row six oars; sometimes only four,

which last is termed a jolly boat. Yawls resemble pinnaces, but are generally rowed with six oars. A wherry is a sharp light boat, used in rivers or harbours. The wherries allowed to ply about London, are either scullers wrought by a single person with two oars, or oars wrought by two persons, with each an oar. A Moses is a flat-bottomed boat used in the West Indies, for bringing off hogsheads of sugar, and is termed single or double, according to its size. A punt is a sort of oblong flat-bottomed boat, nearly resembling a floating stage. A felucca is a large and strong passage-boat, used in the Mediterranean, having from ten to sixteen banks of oars.

**BOAT-HOOK**, an iron hook with a sharp point on the hinder part thereof; it is fixed upon a long pole, by the help of which a boat is either pulled to, or pushed off from, any place.

**BOB** of a *Pendulum*, or **BALL** of a *Pendulum*, is the metallic weight which is attached to the lower extremity of a pendulum rod, by means of a tapped adjusting nut, at such a distance from the point of suspension as the time of a given vibration requires. See **PENDULUM**.

**BODY**, or **SOLID**, in Geometry, is that which has three dimensions, viz. length, breadth, and thickness.

**BODY**, in Physics of Natural Philosophy, is a solid, extended, palpable substance; of itself merely passive, and indifferent either to motion or rest; but capable of any sort of motion, and all figures and forms. Body is composed, according to the Peripatetics, of *matter, form, and privation*; according to the Epicureans and Corpuscularians, of an assemblage of hooked heavy *atoms*; according to the Cartesians, of a certain quantity of *extension*; and according to the Newtonians, of a system of association of solid, massy, hard, impenetrable, moveable *particles*, ranged or disposed in different manners, whence result bodies of different forms, which receive particular denominations, according to the circumstances under which they appear. These elementary or component particles of bodies must be infinitely hard, so as ever to remain unbroken and unchanged; which, as Newton observes, is necessary, in order to the world's remaining in the same state, and bodies continuing of the same nature and texture in several ages.

**BODIES** are either *hard, soft, or elastic*. A *hard Body* is that whose parts do not yield to any stroke or percussion, but retains its figure unaltered. A *soft Body* is that whose parts yield to any stroke or impression, without restoring themselves again. An *elastic Body* is that whose parts yield to any stroke, but immediately restore themselves again, and the body retains the same figure as at first. We know not, however, of any bodies that are perfectly hard, soft, or elastic; but all possess these properties in a greater or less degree.

**BODIES** are also either *solid or fluid*. A *solid Body* is that in which the attractive power of the particles of which it is composed exceed their repulsive power, and, consequently, they are not readily moved one among another, and therefore the body will retain any figure that is given to it. A *fluid Body* is that in which the attractive and repulsive powers of the particles are in exact equilibrio, and therefore yields to the slightest impression. See **SOLID** and **FLUID**.

**Regular BODIES**, or **Platonic BODIES**, are those which have all their sides, angles, and planes, similar and equal, of which there are only the five following, viz.

1. Tetraedron, contained under 4 equilateral triangles.
2. Hexaedron, ..... 6 squares.
3. Octaedron, ..... 8 triangles.
4. Dodecaedron, ..... 12 pentagons.
5. Icosaedron, ..... 20 triangles.

For the method of forming the five regular bodies, as also for finding out the surfaces and solidities, see the respective articles.

**BOILING**. See **EBULLITION**.

**BOMB**, a large shell of cast iron, having a great vent to receive the fusee, which is made of wood. Bombs are of different magnitudes, and are filled with gunpowder and other combustibles. When shot from the mortar, the fusee in them takes fire, and its length is so adjusted, that by the time the shell has finished its flight, the fusee has burnt up, and explodes the gunpowder within so as to burst the shell to pieces just as it is falling to the ground; this, of course, increases its

execution, and causes greater devastation. A grenade resembles a bomb, but is less, and may be cast with the hand. The usual weight of a grenade is three pounds; and filled with a strong powder lighted by a fusee.

**BOOKBINDING**. The leaves being accurately folded, are beaten with a hammer on a stone, to make them smooth, and lie close; they are then put into a press, and sewed on boards, after which the backs are glued, and the bands opened and scraped to fix the pasteboard covers; the back is rounded with a hammer, and the book is fixed in a press, between two boards. Holes are then made for fixing the pasteboards to the volume, which is pressed a third time. It is then put to the cutting-press, between two boards, one lying even with the press for the knife to run upon, the other above for the knife to run against; after this operation, the pasteboards are squared; the leaves sprinkled, by dipping a brush in vermilion and sap green, holding it in one hand, and spreading the hair with the other. The leather covers are moistened, cut to the size of the book, smeared with paste, and afterwards stretched over the pasteboard on the outside, and doubled within, after having taken off the four angles, and indented and platted the cover at the head-band. The book is now covered and bound between two bands, and set to dry. It is afterwards washed with paste and water, and then sprinkled with a brush; if marbling be required on the leathern covers, the spots are made by the addition of vitriol. The book is glazed with the white of an egg, and polished with a hot iron; the letters and ornaments are made with gilding tools, or brass cylinders, rolled along by a handle. To apply the gold, the leather is glazed with whites of eggs diluted with water, when nearly dry the gold leaf is laid on, and the letters, or ornaments, are made with tools heated in a charcoal fire. For preserving books from the depredations of worms,—mineral salts, alum, and vitriol should be mixed with the paste used by bookbinders; and instead of flower, the paste should be made of starch. A little pulverized alum is useful, if strewn between the book and its cover, and upon the shelves of the library. A few drops of any perfumed oil will secure libraries from the consuming effects of mouldiness and damp. Russian leather, which is perfumed with the tar of the birch-tree, never moulders; and merchants suffer large bales of this article to lie in the London docks in the most careless manner, knowing that it cannot sustain any injury from damp.

**BOOM**, in Marine Fortification, a strong iron chain, fastened to a number of spars, and extending athwart the mouth of a harbour or river, to prevent the enemy's vessels from entering, but may be occasionally sunk or removed.

**Boom**, a long pole run out from different places in the ship, to extend the bottoms of particular sails, as jib-boom, flying jib-boom, studding-sail booms, driver or spanker-boom, ring-tail boom, main-boom, square-sail boom, &c.

**Fire Booms**, strong poles occasionally thrust out from a ship's side, &c. to prevent the approach of fireships, firestages, or vessels accidentally on fire.

**Booming**, among Sailors, denotes the application of a boom to the sails. Booming of the sails is never used but in quarter winds, or before a wind. When a ship is said to come booming towards us, it signifies that she comes with all the sail she can make.

**BOOTES** and **MONS MENALUS**, a Constellation in the northern hemisphere. Grecian fable makes Böotes to be Arcas, a son of Jupiter and Calisto. Juno, who was jealous of Jupiter, changed Calisto into a bear; and she was near being killed by her son Arcas in hunting. Jupiter, to prevent further mischief from huntsmen, made Calisto the constellation Ursa Major, and on the death of Arcas, transferred him to heaven, with the title and office of Bear Guard. The splendid star Arcturus, is frequently mentioned in holy writ, particularly in the book of Job. This star is placed near Virgo, in a line with Spica, on the meridian of the Ecliptic. The ancient Greeks called this constellation Lycaon. The Hebrews call it "the Barking Dog." The Latins, among other names, called Böotes *Canis*. Going back to the time when Taurus opened the year, and when Virgo was the fifth of the zodiacal signs, we shall find the brilliant star Arcturus, so remarkable for its red and fiery appearance, corresponding with a period of the year

as remarkable for its heat. Pythagoras, who introduced the true system of the universe into Greece, received it from Oenuphis, a priest of On, in Egypt. And this college of the priesthood was the noblest of the East, in cultivating the studies of philosophy and astronomy. Among the high honours which Pharaoh conferred on Joseph, he very wisely gave him in marriage "a daughter of the priest of On." Joseph is said to have died 1635 years before Christ. The supposed era of the history of the book of Job is fixed 1513 years before Christ. These facts are 900 years prior to the age of Pythagoras. And it is 4000 years since the bull ceased to be the leader of the celestial host. The Greeks cannot then claim the invention of the constellation Böotes.

Boundaries and Contents of this Constellation:—North by Draco, east by Corona Borealis and Serpens, south by Virgo, and west by Canes Venatici and Coma Bernices. Böotes contains 54 stars, namely, one of the 1st magnitude, six of the 3d, eleven of the 4th, &c. Arcturus, the largest star in this constellation, having  $211^{\circ} 54' 16''$  right ascension, and  $20^{\circ} 8' 0''$  N. declination, rises and culminates, at London, as in the following table: Meridian Altitude,  $58^{\circ} 37'$ .

| MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. | MONTH. | RISES.<br>ho. mi. | CULM.<br>ho. mi. |
|--------|-------------------|------------------|--------|-------------------|------------------|

Arcturus rises on the north-east by east point of the compass; and from the circumstance of its variation being greater, in consequence of a proper motion of its own, it is supposed to be the nearest star to the earth of any in the northern hemisphere.

**BOOT-TOPPING**, the operation of scraping off the grass, slime, shells, &c. which adhere to the bottom of a ship, near the surface of the water, and daubing it over with a mixture of tallow, sulphur, and rosin. Boot-topping is chiefly performed where there is no dock.

**BORAX**, in Chemistry, a salt in appearance somewhat like crystals of alum, brought originally from the East Indies in an impure state, and afterwards freed from its impurities by certain processes in the European countries. It was long a matter of uncertainty, whether this salt be a natural or factitious substance in those countries from whence it is brought; but it is now beyond a doubt, that it is naturally produced in the mountains of Thibet, from whence other parts of the eastern continent are supplied. It is produced in the kingdom of Jum-late, about thirty days' journey north from Betowle, a small principality about 200 miles north-east of Lucknow. The place where it is found is said to be a small valley surrounded with snowy mountains, in which is a lake about six miles in circumference; the water of which is constantly so hot that the hand cannot bear it for any time. Around this lake the ground is perfectly barren, not producing even a blade of grass; and the earth is so full of a saline matter, that after falls of rain or snow it concretes in white flakes on the surface, like the natron of Hindostan. On the banks of this lake, in the winter season, when the falls of snow begin, the earth is formed into small reservoirs six inches high; when these are filled with snow, the hot water from the lake is thrown upon it; which, together with the water from the melted snow, remains in the reservoir, to be partly absorbed by the earth, and partly evaporated by the sun; after which, there remains at the bottom a cake of sometimes half an inch thick of crude borax, which is taken up and reserved for use. It can only be made in the winter season, because the falls of snow are indispensably requisite, and also because the saline appearances upon the earth are strongest at that time. When once it has been made on any spot, it cannot be made again on the same spot till the snow has fallen and dissolved three or four times, when the saline efflorescence appears as before.

**BORING**, in a general sense, the art of perforating, or making a hole through any solid body. Boring of waterpipes is as follows:—The poles of alder, which is a very useful wood

in making pumps, waterpipes, &c. being laid on horses or trestles of a foot height, to rest the auger upon while they are boring, they set up a lathe to turn the least end of the poles, to fit them to the cavities of the great end of the others. They turn the small ends of the poles about five or six inches in length, to the size they intend to bore the bigger ends about the same depth, viz. five or six inches. This is designed to make a joint to shut each pair of poles together, the concave part being the female part, and the other the male of the joint. In turning the male part, they turn the channel in it, or a small groove at a certain distance from the end, and in the female part they bore a small hole to fit over this channel. This being done, they bore the poles through; and to prevent them from boring out at the side, they stick great nails at each end to be a guide in boring. It is usual, however, to bore them at both ends; so that a crooked pole can be bored through and not spoil it.

**BORING**, in Farriery, a cruel and absurd method of treating a wrenched shoulder.

**BORING**, in Mineralogy, a method of piercing the earth with scooping irons, which being drawn back at proper times, bring up with them samples of the different strata through which they have passed; by the examination of which, the skilful mineralogist will be able to guess whereabouts a vein of ore, or a stratum of coal, may lie; or whether it will be worth while to open a mine for the purpose of working it.

**BOSCOVICH**, ROGER JOSEPH, a very eminent mathematician and philosopher, was born May 11, 1711, at Ragusa. He studied Latin grammar in the schools which were taught by the Jesuits, in his native city, until 1725, when, in consistence with a maxim of the Jesuits, to send their most eminent pupils to Rome for the completion of their education, he was removed to that city. After this he soon acquired very great reputation for his eminent attainments in divinity and science: at three successive periods he became professor of mathematics and astronomy at Rome, at Pavia, and at Milan. When the order of Jesuits was suppressed, he was invited to Paris, and received the place of director of the optical instruments of the marine. Previous to this, however, he had been employed, in conjunction with father Maire, in measuring a degree of the meridian in Italy, and in correcting the maps of the papal state. He published in 1755, an interesting account of the expedition in which these objects were effected. He had also been employed in adjusting a disagreeable affair between the republic of Lucca and the regency of Tuscany; and in a similar business between the republic of Ragusa and the court of Great Britain; which brought him to London, where he soon became acquainted with the most celebrated British philosophers. He remained at Paris ten years, but being a foreigner, his celebrity was envied; this, together with the irreligion which then prevailed among the French philosophers, was disagreeable to him, so that he obtained leave for two years' absence to revisit his friends in Italy. He tarried at Bassano, where he printed five volumes in large octavo, containing a real treasure of optical and astronomical knowledge. From Bassano he went to Rome, and thence to Milan, where he took up his abode, being in the neighbourhood of his favourite observatory at Brera. Here he continued to enjoy the pleasures of study; and, occasionally, the society of many respected friends, until his two years of absence were nearly expired: his unwillingness to leave Italy, and at the same time a solicitude to avoid the charge of ingratitude from the French nation, occasioned great perplexity of mind, which was followed by deep melancholy, a disordered imagination, and, at length, direct insanity. He had, indeed, some lucid intervals, and once there were hopes of a recovery; but he soon relapsed, and an imposthume breaking in his breast, put an end to his mortal existence in February, 1787, in his 76th year.

**BOSSAGE**, in Architecture, a term used for any stone that has a projecture, and is laid rough in a building, to be afterwards carved into mouldings, capitals, coats of arms, &c. Bossage is also that which is otherwise called rustic work; and consists of stones which advance beyond the naked or level of the building, by reason of indentures or channels left in the joinings. These are chiefly used in the corners of edifices, and thence called rustic quoins. The cavities or indentures are

sometimes round, sometimes chain-framed, or bevelled, sometimes in a diamond form, sometimes enclosed with a cavetto, and sometimes with a listel.

**BOTANY.** The history of the vegetable kingdom, or, as it is termed, *Botany*, is a science which includes the practical discrimination, the methodical arrangement, and the systematic nomenclature, of vegetables. Vegetables are organized productions, supported by air and food, endowed with life, and subject to death, like animals. They have, in some instances, *spontaneous*, not voluntary motion. They are sensible to the supply of nourishment, the action of the air and light, and thrive or languish according to the wholesome application of these stimulants. This is evident to all who have ever seen a plant growing in a situation for which it is not suitable. Those who have gathered a rose, know how soon it withers; and the familiar application of its fate to that of human life and beauty, is not more striking to the imagination, than philosophically correct.

The external covering of plants is commonly transparent and smooth; but sometimes it is downy; and sometimes so hard, that flint has been detected in its composition. The Dutch rush serves as a file to polish wood, ivory, and even brass. Under the cuticle, is found the *cellular integument* of a pulpy texture, and the seat of colour. It is usually green in the leaves and stems, and is dependent for its hue on the action of light. When the cellular integument is removed, the bark presents itself; in plants and branches only one year old, the bark consists of a simple layer. In the branches and stems of trees, it consists of as many layers as they are years old. The Peruvian bark affords 'a cooling draught to the fevered lip;' that of the cinnamon yields a rich cordial; that which is stripped from the oak, is used for tanning. Immediately under the bark is situated the wood, which forms the great bulk of trees and shrubs. This also consists of numerous layers, as may be observed in the fir, and other trees; and from these concentric circles, the age of the tree is determined. Within the centre of the wood is the *medulla* or pith, a cellular substance, juicy when young, extending from the roots to the summits of the branches. In some plants, as in grasses, it is hollow, merely lining the stem. The trunk enlarges by the formation of the new *liber*, or inner bark, every year, the undermost layer is transformed into *cortex*, or outer bark, becoming the *laburnam*, or soft wood of the next, and the laburnam becoming the *lignum*, or hard wood.

The chemical or elementary principles of vegetables, are, carbon, water, and air; or hydrogen 15 parts, and oxygen 85 parts, for the constituent parts of 100, water; and azote and nitrogen 72, and oxygen 28, as the constituent parts of 100, atmospheric air, and carbon.

Vegetables generate or give out oxygen or vital air, in the light or sunshine, by a natural process of their own. The saccharine and oily productions of vegetables are parts of their sap or juices; but the turpentine, bitter, and acid principles, are effects of secretion. The green colour of vegetables arises from the oil they contain; the rays of the sun extract the oxygen from the outer surface, and leave the carbon and hydrogen the constituent parts of oil. Healthy vegetables, in general, perspire water by the under part of their leaves, equal to one-third of their weight, every twenty-four hours. Nor do they derive their substance in a principal degree from the matter of the soil in which they grow; but they are created as it were by a vital principle of their own, out of air and water, and of the imperceptible matters combined with air and water, from which they derive distinctions of smell, taste, and substance.

The general constituent principles of vegetables, viz. hydrogen, carbon, oxygen, &c. do not exist in them in a simple and uncombined state, but joined in various proportions, forming compound substances, that make up the whole vegetable; and the following are the principal substances met with in vegetables:—1 Mucilage. 2. Fixed and volatile oil. 3. Resin. 4. Gum resins. 5. Caoutchouc. 6. Camphor. 7. Wax. 8. Honey. 9. Sugar. 10. Gluten. 11. Fecula. 12. Tannin. 13. Woody fibre. 14. Colouring matter. 15. Acids. 16. Miscellaneous substances.—17. Amber, and 18. Asphaltum, are also supposed to be of vegetable origin.

**Mucilage.** Various parts of vegetables impart to water, if boiled with them, a certain viscous matter, causing consistency. This is called mucilage. Some trees suffer their mucilage to transude, some spontaneously, or by incisions made in them. When it has become concrete by drying in the air, it is called gum. In this way gum arabic, gum senegal, and cherry-tree gum, are formed. Mucilage is without taste; soluble in water, but not in oils or alcohol. It is not changed by exposure to the air. From the experiments of Cruikshank, it appears to consist of oxygen, hydrogen, nitrogen, carbon, and lime.—**Fixed and Volatile Oils.** Oil is composed of carbon and hydrogen, with a small portion of oxygen. Oils are divided into fat or fixed oils, and volatile or essential oils. Fixed oil is usually obtained by expression, chiefly from the seed and kernels of plants. Volatile oil is procured by distilling aromatic plants with water.—**Resins** exist in the vessels of certain trees, and frequently exude from them spontaneously. Sometimes they are procured by making incisions in the trees, and sometimes by distilling the wood. They are considered as volatile oils combined with oxygen. They are soluble in alcohol and oils, but not in water. It is this property that renders them so valuable as varnishes. They are very inflammable, and melt with a slight heat. The principal resins are the turpentine, the guaiacum, mastic, copal, and sandarac.—**Gum resins** appear to be a natural mixture of resin and mucilage. They are partly soluble in water, and partly in alcohol. Gum ammoniac, assafoetida, and opium, are gum resins.—**Caoutchouc**, elastic gum, or Indian rubber, resembles a resinous gum. It is elastic, inflammable, and insoluble in water or fat oils. It is partly soluble in volatile oils, and entirely so in nitric ether. It is the juice of a tree of the euphorbia tribe. When first exuded, it is of a milky consistence and colour, but it gradually thickens, and is blackened by smoke, as it flows round the clay balls on which the bottles are made. It is cut easily, if the knife be dipped in water.—**Camphor**, a volatile oil, is extracted from a species of laurel which grows in China, and the East Indies. It is very inflammable, and sublimed by a gentle heat. It is soluble in ether, alcohol, the oils, and acetic acid. It is highly odorous, and prevents the spreading of contagious disorders.—**Wax**, a vegetable substance, found in the greatest quantity on the anthers of flowers, and collected by bees, is insoluble in water and alcohol, but soluble in volatile and fixed oils. It is very inflammable. Its components are the same as those of volatile oils.—**Honey** is formed chiefly in the pistils or female organs of flowers, whence it is collected by the bees: it appears to be sugar dissolved in mucilage.—**Sugar** is produced in the greatest quantity from the sugar cane; but it may also be obtained from the sugar maple, the beet-root, carrot, &c. Its constituents are oxygen, carbon, and hydrogen.—**Gluten**, an elastic viscid substance, is found in vegetables, and chiefly in wheat flour; it is soluble in water, and very slightly so in alcohol.—**Fecula**, or **Starch**, forms the principal part of the substance which is washed away in order to obtain the gluten from the grain. When the fluid is suffered to stand, a white powder subsides, which is the starch. It is also obtained from potatoes.—**Tannin** matter is found in the gall nut, the bark of oak trees, and other astringent parts of vegetables.—**Woody fibre**, constituting the basis of wood, may be separated from every other substance, by boiling wood shavings in water to dissolve the extractive matter, and then in alcohol to separate the resins, &c.—**Colouring matter** is found in vegetables combined with, 1, the extractive principle; 2, with resins; 3, with fecula; 4, with gum.—**Acids**, existing ready formed in vegetables, are the citric, malic, oxalic, gallic, benzoic, tartaric, acetic, &c. Besides which, we find various other substances in vegetables, as sulphur, iron, manganese, lime, alumine, magnesia, barytes, &c.

Roots are necessary to fix and hold plants in the earth, from which they imbibe nourishment. Roots are either annual, or living for one season, as in barley; biennial, which survive one winter, and, after perfecting their seed, perish at the end of the following summer, as wheat; or perennial, which remain and produce blossoms for an indefinite number of years, as those of trees and shrubs in general. The root consists of two parts: the *caudex* or stump, which is the body or knot of the root, from which the trunk and branches ascend, and the fibrous roots

W. Swell Sculp.

branching from the *caudex*.—Buds are, in most instances, guarded by scales, and furnished with gum or woolliness, as an additional defence. Buds are various in their forms, but very uniform in the same species, or even genus. They unfold the embryo plant.—The trunk of a tree includes the stems or stalks. The stem, as it advances in growth, either supports itself, or twines round other bodies. It is either simple, as in the lily; or branched, as in other plants.—Leaves are generally so formed as to present a large surface to the atmosphere. When of any other hue than green, they are said to be coloured. The internal surface of a leaf is vascular and pulpy, clothed with a cuticle, very various in different plants, but its pores are always so constructed, as to admit of the requisite evaporation or absorption of moisture, as well as to admit and give out air, and light also acts through this cuticle.

The effect of moisture must have been observed by every one. By absorption from the atmosphere, the leaves are refreshed; by evaporation, when separated from their stalks, they soon fade and wither. The nutritious juices, imbibed from the earth, become sap, and are carried by appropriate vessels into the substance of the leaves, and these juices are returned from each leaf into the bark. This is effected by a double set of vessels, analogous to the arteries and veins in animals, and is the circulation of the vegetable blood or sap. The sap is carried into the leaves for the purpose of being acted upon by air and light, with the assistance of heat and moisture, and by all these agents, a most material change is wrought in the component parts of the sap, according to the nature of the secretions. The green colour of the leaves is owing to the action of light, but they are subject to a disease by which they become partially spotted or streaked, and in this state are variegated. The irritable nature of leaves is very extraordinary, for the sensitive plant, common in hot-houses, when touched by any extraneous body, folds up its leaves one after another, and the footstalks droop, as if dying.

Props, or *falera*, are appendages to the true leaves, or to their stalks. Inflorescence, treats of the different kinds or modes of flowering. Sometimes the flowers surround the stem in a garland or ring, as in mint, deadnettle, &c. In other plants, a cluster, which bears several flowers, each on its own stalk, like a bunch of currants. In other plants, numerous crowded flowers are ranged along an upright, common stalk, expanding progressively, as in wheat and barley. Again, we find a flat-topped spike, as in the cabbage and wallflower.

Fructification is a term comprehending not only the parts of the fruit, but those of the flower. The parts of fructification are described by many technical words, but include chiefly the flowercup, or external covering of the flower; the calix, consisting in general of the coloured leaves of the flower; the stamens, and the cells containing the pollen or fecundating dust: the pistils stand in the centre of the circles formed by the stamens, and consist of the germen or rudiments of the future fruit or seed; the seed are composed of the embryo or germ, and are often accompanied by accessory parts; as spines, hooks, scales, and crests, generally serving to attach such seeds as are furnished with them, to the rough coats of animals, and thus promote their dispersion.

Classification, though last in order, is first in importance; and of all the systems of botany, that of Linnæus, now generally acknowledged and adopted, is founded on the number, situation, and proportion of the stamens and pistils, whose uses and structure have been just explained. The following twenty-four Classes owe their distinctions principally to the stamens.

#### THE CLASSES; or, Primary Divisions of the Sexual System. (See the Plate.)

Fig. 1. *MONANDRIA*, flowers with one stamen.—2. *DIANDRIA*, flowers with two stamens.—3. *TRIANDRIA*, flowers with three stamens.—4. *TETRANDRIA*, flowers with four stamens, all of the same length.—5. *PENTANDRIA*, flowers with five stamens.—6. *HEXANDRIA*, flowers with six stamens, all of the same length.—7. *HEPTANDRIA*, flowers with seven stamens.—8. *OCTANDRIA*, flowers with eight stamens.—9. *ENNEANDRIA*, flowers with nine stamens.—10. *DECANDRIA*, flowers with ten stamens.—11. *DODECANDRIA*, flowers with twelve stamens.

—12. *ICOSANDRIA*, flowers with about twenty stamens, attached to the calix, or sometimes, in part, to the corolla.—13. *POLYANDRIA*, flowers most commonly with more than twenty stamens, attached to the receptacle.—14. *DIDYNAMIA*, flowers with two longer stamens.—15. *TETRADYNAMIA*, flowers with four longer stamens.—16. *MONADELPHIA*, filaments united into one brotherhood.—17. *DIADELPHIA*, filaments forming two brotherhoods.—18. *POLYADELPHIA*, filaments forming more than two brotherhoods.—19. *SYNGENESIA*, anthers united, composing a hollow cylinder, through which the style passes.—20. *GYNANDRIA*, stamens on the pistil.—21. *MONŒCIA*, staminate and pistilliferous flowers on the same plant.—22. *DIOŒCIA*, staminate and pistilliferous flowers on different plants.—23. *POLYGAMIA*, different dispositions on the same plant.—24. *CRYPTOGAMIA*, flowers inconspicuous.

#### THE ORDERS; or, Secondary Divisions of the Sexual System.

Fig. 1. *Monogynia*, containing hermaphrodite flowers with one pistil, or female organ.—2. *Digynia*, hermaphrodite flowers with two pistils; *a*, the pistils detached from the flower.—3. *Trigynia*, hermaphrodite flowers with two pistils; *a*, the pistils separated from the flower.—4. *Tetragynia*, hermaphrodite flowers with four pistils; *a*, the pistils separated from the flower.—5. *Pentagynia*, hermaphrodite flowers with five pistils; *a*, the pistils separated from the flower.—6. *Hexagynia*, hermaphrodite flowers with six pistils; *a*, the pistils separated from the flower.—7. *Heptagynia*, hermaphrodite flowers with seven pistils; *a*, the pistils detached from the flower.—8. *Decagynia*, hermaphrodite flowers with ten pistils; *a*, the pistils separated from the flower.—9. *Dodecagynia*, hermaphrodite flowers with twelve pistils, or female organs.—10. *Polygynia*, hermaphrodite flowers containing an indefinite number of pistils, or female organs.—11. *Gymnospermia*, the name of the first order in the class *DIDYNAMIA*; in which *a* represents a longitudinal section of the flower, to display the four naked seeds in the bottom of the calix.—12. *Angiospermia*, the name of the second order in the class *DIDYNAMIA*, containing such hermaphrodite flowers with four stamens, two longer than the others, as have their seeds contained in a vessel; *a*, the pericarp, or vessel, detached from the flower.—13. *Siliculosa*, the first order in the class *TETRADYNAMIA*, containing such flowers possessed of the classical character, as have their seeds contained in a short round pod; *a*, the *silicula*, or pod, divided, to shew the seeds separated from the flower.—14. *Siliquosa*, the second order in the class *TETRADYNAMIA*, containing such flowers possessed of the classical character, as have their seeds contained in a *siliqua*, or long slender pod, to each suture of which they are alternately attached; *a*, the *siliqua* detached.—15. *Polygamia Equalis*, the first order in the class *SYNGENESIA*; *a*, a floret separated from the aggregate.—16. *Polygamia Superflua*, the second order in the class *SYNGENESIA*; *a*, represents a female floret in the circumference or ray; *b*, an hermaphrodite floret in the centre or disk.—17. *Polygamia Frustranea*, the third order in the class *SYNGENESIA*.—18. *Polygamia Necessaria*, the fourth order in the class *SYNGENESIA*.—19. *Polygamia Segregata*, the fifth order in the class *SYNGENESIA*; *a*, a floret with its proper flower-cup detached from the aggregate.—20. *Monogamia*, the sixth order in the class *SYNGENESIA*; *a*, representing a section of the flower, to exhibit the union of the stamens by the anthers.—21, 22, 23. *Triœcia*, the third order in the class *POLYGAMIA*, in which hermaphrodite flowers are intermingled with male or female flowers, or both, on one, two, or three plants.—24. *Filices*, Ferns, the first order; 25. *Musci*, Mosses, the second order; 26. *Algæ*, Sea-weed, &c. the third order; 27. *Fungi*, Mushrooms, the fourth order; in the class *CRYPTOGAMIA*.

In the class *CRYPTOGAMIA* two other orders are reckoned, *viz.* *HEPATICÆ*, small herbaceous plants resembling Mosses; and *MISCELLANÆ*, including plants not easily referable to any of the five foregoing orders.

The orders, or subdivisions of the classes, are generally marked by the number of the pistils, or by some other circumstance equally intelligible. The names of these, as well as of the classes, are both of Greek derivation, and designate the functions of the respective organs. A further division of the orders, founded on distinctions in the nectarium, lead to

*genera.* Other divisions of the genera, in regard to the root, trunk, leaves, &c. lead to *species*; and casual difference in species are called varieties.

We have, in the American reed, an instance of the *Monandria monogynia*, that is, a flower with one stamen and one pistil. In the jasmine we see an instance of the *Diandria monogynia*, or flower that has two stamens and one pistil. In the linum or flax, there are five stamens and five pistils; and the flower is called *Pentandria pentagynia*, that is, one having five males and five females; and so of the rest.

The study of Botany has been applied as a guide to estimate the qualities of plants. The first order of the fourteenth class, denominated "*Didynamia gymnospermia*," are all innocent or wholesome; those of the other order are febrile, narcotic, and dangerous, being allied to a large part of the *Pentandria monogynia*, known to be poisonous, as containing henbane, nightshade, and tobacco. The whole class *Tetradynamia* is wholesome. Whenever the stamens are found to grow out of the calyx, they indicate the pulpy fruits of such plants to be wholesome, except the seeds of the laburnum, which, if eaten unripe, are violently emetic and dangerous. Milky plants are generally to be suspected. Umbelliferous plants, which grow in dry or elevated situations, are aromatic, safe, and often wholesome, while those that inhabit low and watery places are among the most deadly poisons.

The natural substances found in all vegetables are, sugar, in the sugar-cane, beet, carrots, &c.; gum, or mucilage, oozing from many trees; jelly, procured from many fruits; turpentine and tar, from the pine; bitters, from hops and quassia; and the narcotic principle from the milk of poppies, lettuce, &c.

The vegetables of greatest value to man, produce gluten or starch; as wheat, potatoes, barley, beans, &c. Oils are produced by pressing the seeds or kernels of vegetables; as olives, almonds, linseed, &c. Volatile oils are distilled from peppermint, lavender, &c. Wax is collected from all flowers by bees. Resins exude like gum from firs and other trees; and are known as balsams, varnishes, turpentine, tar, pitch, &c. Of this class too, is Indian rubber; which is a gum that exudes from a certain tree in South America. And iron also mixes with the substance of most vegetables, and is the cause of the beautiful colours of flowers. Potash is obtained from the ashes of burnt vegetables; as kelp, vine, fern, &c.

*Anatomy of Plants.*—In order to comprehend this subject, the following general principles may be of service; they may be verified in most plants; and observation is here the best teacher. 1. First, all plants do not perspire. 2. That there is not in all plants an uniform circulation of sap. 3. In general, the spiral wire is the muscle of the plant. 4. The leaves are for the most part the lungs of the plant. 5. The different divisions of the leaves are formed of the elongations of the bark and inner bark vessels. 6. Hairs and instruments of that kind are the means which Nature takes to form the different juices according to their various affinities. That these figures were taken for perspiration, but are in reality liquids received from the atmosphere and flowing into the plant, not a juice running from it. 7. The root is the grand laboratory of all plants, where the great chemical operations are going on. 8. The heart of the seeds is formed in the extremities of the side roots. 9. The flower is also formed in the middle root, and the pollen in the taproot. 10. The corolla of a flower is formed by bubbles of water placed in rows, and owes all its beauty, and the lightness of its tint, to the refraction and reflection of the sun on the drops of water which form its pabulum. This thought of apparent subtilty is nevertheless verified by experiment. 11. The roots and leaves of a plant will most exactly mark not only what is the soil in which they originally grew, but the situation from which they came, whether a water plant or a dry plant, a rock or a valley plant, &c. 12. The water, semi-water, and rock plants alone can be said to have direct air-vessels, though these may be found in parasite and early spring plants, such as the crocus and hyacinth.

**BOWSPRIT**, a large boom or mast, which projects over the stem, to carry sail forward, and counteract the force of the aftersails, or those extended behind. The bowsprit should be two-thirds of the length of the mainmast, and its thickness equal to the mizenmast: when it is twelve fathoms five feet

long, its yard must be eight fathoms two feet long, and the topmast of the bowsprit three fathoms and one foot.

**BOYLE, ROBERT**, one of the greatest philosophers of the seventeenth century, was born at Lismore, in Ireland, January 25, 1626, the year in which the sciences were deprived of their greatest ornament, Lord Bacon, whose plans of experimental philosophy our author afterwards so ably seconded and improved. Boyle was one of the first of those illustrious men who formed the Royal Society, in 1645, for the purpose of improving experimental knowledge, upon the plan laid down by Bacon; which society being, in 1654, removed to Oxford, he went to reside there, where he very much improved the air-pump, which led him to the discovery of several of the properties of air. He also published, during his residence at Oxford, several works relating to the properties of air, and other philosophical subjects; and in 1668 returned to London, where he continued to reside till his death, which happened in the year 1691, in the 65th year of his age. Boyle was author of a very great number of important works, beautiful editions of which have been published in London, in five volumes folio, and six volumes quarto. Dr. Shaw also published, in three volumes quarto, the same works "abridged, methodized, and disposed under the general heads of Physics, Statics, Pneumatics, Natural History, Chemistry, and Medicine;" to which he has prefixed a short catalogue of the philosophical writings, according to the order of time when they were published, &c.

**BRAHE, TYCHO**, a famous Danish astronomer, born of a noble family, in Knudstorp, 1546, read lectures on astronomy at Copenhagen, in 1574, by order of the king; who also built for him an observatory in the isle of Huen in the Sound, the building being called Uranibourg, where he resided about 20 years, pursuing his studies, making observations, and receiving visits from the most illustrious personages. On the death of the king he lost his pension, and went to Prague, where he was introduced to the emperor Rodolphus: who treated him respectfully; gave him a magnificent house, fit for astronomical observations; and assigned him a pension of 3000 crowns. Here then he settled in the latter part of 1598, with his sons and scholars, and among them the celebrated Kepler. But he did not long enjoy this happy situation; for, about three years after, he died, in the 55th year of his age, and was interred in a very magnificent manner in the principal church at Prague, where a noble monument was erected to him; leaving, beside his wife, two sons and four daughters. The skill of Tycho Brahe in astronomy is universally known, and his works are very numerous and valuable.

**BRAMAH'S MACHINE**, or *Hydrostatic Press*, &c. consists in the application of water, or dense fluids, to engines, so as, in some instances, to cause them to act with immense force; in others, to communicate the motion and powers of one part of a machine to some other part of the same machine; and, lastly, to communicate the motion and force of one machine to another, where local situations preclude the application of other methods of connexion.

The first and most material part of this invention will be clearly understood by an inspection of the figure in the next page, where A is a cylinder of iron, or other materials, sufficiently strong, and bored perfectly smooth and cylindrical; into which is fitted the piston B, which must be made perfectly water-tight, by leather or other materials, as used in pump-making. The bottom of the cylinder must also be made sufficiently strong with the other part of the surface, to be capable of resisting the greatest force or strain that may at any time be required. In the bottom of the cylinder is inserted the end of the tube C; the aperture of which communicates with the inside of the cylinder, under the piston B, where it is shut with the small valve D, the same as the suction-pipe of a common pump. The other end of the tube C communicates with the small forcing-pump or injector E, by means of which, water or other dense fluids can be forced or injected into the cylinder A, under the piston B. Now, suppose the diameter of the cylinder A to be 12 inches, and the diameter of the piston of the small pump or injector E only one quarter of an inch, the proportion between the two surfaces or ends of the said pistons will be as 1 to 2304; and supposing the intermediate space between them to be filled with water or other dense

fluid capable of sufficient resistance, the force of one piston will act on the other just in the above proportion, viz. as 1 is to 2304. Suppose the small piston in the injector to be forced down when in the act of pumping or injecting water into the cylinder A, with the power of 20 cwt. which could easily be done by the lever H; the piston B would then be moved up with a force equal to 20 cwt. multiplied by 2304. Thus is constructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raised by a simple lever, through equal space, in much less time than could be done by any apparatus constructed on the known principles of mechanics; and it may be proper to observe, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being usefully extended beyond a certain degree; but in machines acted upon or constructed on this principle, every difficulty of this kind is obviated, and their power subject to no finite restraint. To prove this, it will be only necessary to remark, that the force of any machine acting upon this principle can be increased *ad infinitum*, either by extending the proportion between the diameter of the injector and the cylinder A, or by applying greater power to the lever H.

The second figure represents the section of an engine, by which very wonderful effects may be produced instantaneously by means of compressed air. AA is a cylinder, with

the piston B fitting air-tight, in the same manner as described in the first figure. C is a globular vessel made of copper, iron, or other strong materials, capable of resisting immense force, similar to those of air-guns. D is a strong tube of small bore, in which is the stop-cock E. One of the ends of this tube communicates with the cylinder under the piston B, and the other with the globe C. Now, suppose the cylinder A to be the same diameter as that in the first figure, and the tube D equal to one quarter of an inch diameter, which is the same as the injector, in the same figure; then, suppose that air is injected into the globe C, (by the common method,) till it presses against the cock E with a force equal to 20 cwt. which can easily be done; the consequence will be, that when the cock E is opened, the piston B will be moved in the cylinder AA with a power of force equal to 2304 tons; and it is obvious, as in

the case in the first figure, that any other unlimited degree of force may be acquired by machines or engines thus constructed.

The third figure is a section, merely to shew how the power and motion of one machine may, by means of fluids, be transferred or communicated to another, let their distance and local situation be what they may. A and B are two small

tubes, smooth and cylindrical; in the inside of each of which is a piston, made water and air tight, as in the first and second figures. CC is a tube conveyed under ground, or otherwise, from the bottom of one cylinder to the other, to form a communication between them, notwithstanding their distance be ever so great; this tube being filled with water or other fluid, until it touch the bottom of the piston; then, by depressing the piston A, the piston B will be raised. The same effect will be produced *vice versa*; thus, bells may be rung, wheels turned, or other machinery put invisibly in motion, by a power being applied to either.

The fourth figure is a section, shewing another instance of communicating the action and force of one machine to another; and how water may be raised out of wells of any depth, and at any distance from the place where the operating power is applied. A is a cylinder of any required dimensions, in which is the working piston B, as in the foregoing examples:

into the bottom of this cylinder is inserted the tube C, which may be of less bore than the cylinder A. This tube is continued, in any required direction, down to the pump cylinder D, supposed to be fixed in the deep well EE, and forms a junction therewith above the piston F; which piston has a rod G, working through the stuffing-box, as is usual in a common pump. To this rod G is connected, over a pulley or otherwise, a weight H, sufficient to overbalance the weight of the water in the tube C, and to raise the piston F when the piston B is lifted: thus, suppose the piston B is drawn up by its rod, there will be a vacuum made in the pump cylinder D, below the piston F; this vacuum will be filled with water through the suction pipe, by the pressure of the atmosphere, as in all pumps fixed in air. The return of the piston B, by being pressed downwards in the cylinder A, will make a stroke of the piston in the pump cylinder D, which may be repeated in the usual way by the motion of the piston B, and the action of the water in the tube C. The rod G of the piston F, and the weight H, are not necessary in wells of a depth where the atmosphere will overbalance the water in the suction of the pump cylinder D, and that in the tube C. The small tube and cock in the cistern

I are for the purpose of charging the tube C.—By these means, it is obvious, most commodious machines, of prodigious power, for tearing up trees, &c. and susceptible of the greatest strength, may readily be formed. If the same multiplication of power be attempted by toothed wheels, pinions, and racks, it

is scarcely possible to give strength enough to the teeth of the racks, and the machine becomes very cumbersome and of great expense. But Mr. Bramah's machine may be made abundantly strong in a very small compass. It only requires very accurate execution. Mr. Bramah, however, was greatly mistaken, says Dr. Gregory in his *Mechanics*, when he published it as the discovery of a new mechanic power. The principle on which it depends has been well known for nearly two centuries; and it is matter of surprise that it has never before been applied to any useful practical purpose.

**BRANDY.** The genuine spirit is distilled from wine, (properly so called, being the wine of grapes,) also from the lees of wine, and the husks of the grapes which remain after pressing out the juice. The usual apparatus is employed, of a still that holds five or six quintals, with a capital and worm applied in the usual manner. Brandy has a purer and more vinous taste than other spirits; its peculiar flavour, no doubt, depends on the nature of the volatile principles, or essential oils, that rise in distillation with the pure spirit, and likewise in some measure upon the wood of the cask in which it is kept. The brandies made in France are much preferred to those of Spain and other countries. This preference is, perhaps, as much owing to superior distillation, as to certain peculiarities in the flavour of the grapes, which differ on every soil and in every climate. In the south of France alone, there is a great variety in the grapes, as well as in the quality of the spirit extracted from them. Some wines are considered totally unfit for distillation; others peculiarly suited for it, and unfit for wine. When the fermentation has proceeded too far, the wine is put into the still, and the spirit extracted; otherwise the acetic acid, by the continuance of the fermentation, would be soon produced in such abundance, as to turn the whole liquid into vinegar. The inferior weak wines are generally employed for the making of brandy, from their containing too little spirit to keep them; and the good, strong wines, are generally reserved as yielding a far ampler profit than could be obtained by the extraction of their spirit. The most spirituous wines of France, are those of Languedoc, Guienne, and Rousillon, which yield, according to Chaptal, from twenty to twenty-five gallons of excellent brandy out of a hundred; but those of Burgundy and Champagne much less. Brisk wines, which contain much carbonic acid, from the fermentation having been stopped at an early period, yield the least spirit. The brandies generally esteemed as the best and finest flavoured are those distilled from the grapes which are the produce of the territories of Cogniac and Andaye. Hence every wine merchant in England is professedly stocked with the "real Cogniac" brandy; and thus every public-house sells no other brandy than the "best Cogniac;"—even the distiller himself has the "genuine Cogniac," which he will tell you he has received "circuitously," and truly so, for it has made all the revolutions of his still-worm in its passage to him. In distillation, the three principal distinctions, in the various strengths of spirits, are described by the terms, low wines, proof spirit, and alcohol. Low wines consist of one-sixth of pure spirit, or alcohol, to five of water;—proof spirit consists of one half of alcohol, and one half of water; and alcohol, wholly of pure spirit.

**BRANDENBURGIUM SCEPTUM**, the Sceptre of Brandenburg, is a modern constellation, formed in 1688, by Geoffroi Kirch, one of the first astronomers of the Duke of Prussia. This asterism is easily distinguished by four stars, situated nearly perpendicular to the equator, and lying between the turn of the river Eridanus, Orion, and the Hare; and these constellations define the boundaries of this *insigne regiminis*.

**BRASS, Making of.** Brass is a factitious metal, made of copper and zinc. By long calcination alone, and without the mixture of any other substance, brass affords a beautiful green or blue colour for glass; but if it be calcined with powdered sulphur, it will give a red, yellow, or chalcedony colour, according to the quantity and other variations in using it. Brass is of a yellow colour, more fusible than copper, and not so apt to tarnish. Pure brass is not malleable unless hot; when cold it will break, and will not bear the hammer when it has been twice melted. To render it soft and pliable, and capable of being wrought, seven pounds of lead are added to an hundred weight of brass. It is peculiarly adapted for wire, being

capable of great extension, and is much used in watch-work. Corinthian brass, so famous in antiquity, was a mixture of gold, silver, and copper. Brass colour is a preparation intended to imitate brass; of which there are two sorts, the red brass or bronze, and the yellow or gilt brass; the last is made only of copper filings; with the former, red ochre, finely pulverized, is mixed, but both are used with varnish. The appearance of brass is given to other metals, by washing them with a yellow lacquer or varnish, much to the detriment of the manufactured article.

Gold lacquer for brass-work may be thus made:—Put an ounce of turmeric powder, two drachms of anatto, and two of saffron, into a pint of alcohol, shake the whole occasionally during a week, and then filter it into a clean bottle. Three ounces of clean seed-lac are then to be added, and the bottle shook occasionally during a fortnight. The mixture will now be a fine lacquer for brass, which will give that metal the appearance of burnished gold. In using it, the metal should be just warmed, and the varnish be laid on evenly with a brush, passing it directly across the work. Small articles may be dipped in the lacquer.

**BREAD**, the staff of life, is used by all people in one way or another, even though composed of materials very dissimilar. We use wheaten bread; some use bread made of oats, others convert dried fish into meal for bread; and nature furnishes the bread-fruit tree to natives of the South-Sea islands.

The bread-fruit tree grows abundantly on the Ladrone Islands. In the Society Islands it is as large as a moderate sized oak; its leaves are about a foot and a half long, of an oval shape, like those of the fig-tree, which they resemble in colour; and, when broken, exude a milky juice. The fruit is shaped like a heart, and grows to the size of a child's head. Its rind is thick, green, and covered with excrescences. The internal part of the rind is a pulpy substance, full of twisted fibres; this pulp is softer towards the middle, where a small cavity is formed, containing no kernels or seeds. It affords much nourishment, and is very satisfying. Its taste is harsh, and similar to potato-bread. The cassava bread of the Americans is made from a species of starch prepared from the roots of a plant. They are peeled and pressed; the juice which exudes is a deadly poison, used by the Indians to poison their arrows. The white starch, however, which is deposited, when properly washed, is perfectly innocent, and makes bread.

The materials of which loaf-bread is principally made, are the seeds of farinaceous vegetables, as wheat, rye, and barley. Potatoes, oats, beans, pease, rice, maize, millet, buck-wheat, &c. contain no gluten, and cannot be made into bread without a certain quantity of flour. The component parts of wheaten, barley, and rye flour, are starch, gluten, and saccharine mucilage.

Fecula, or starch of wheaten flour, forms the most nutritive part of grain. It is found in all seeds, and is very abundant in the potato, as almost all the root consists of starch. 2. Gluten, is the principal substance contained in wheaten flour. It is necessary for the production of good light bread; the quality of the bread being exactly in proportion to the quantity of the gluten contained in the flour; wheat flour alone contains it in any considerable quantity. Flour could not be made into bread without gluten, for the dough rises in consequence of this substance. To obtain gluten, you put a handful of flour into a cloth, pass it through water, and press it with the hand; the starch or fecula passes off, and this elastic substance remains. Gluten forms one-fifth part of bread-corn, ferments readily, and is soluble in acids, but not in water. 3. Saccharine mucilage is soluble in cold water, and separable from it by evaporation. The saccharine part may be converted into an ardent spirit, but the mucilage in bread that has been kept some time, tends to acidity, and becomes mouldy. There are three general methods of making bread, and these we will now illustrate:—1. Unleavened bread is made of flour mixed with water. The sea and other biscuits, the Jews' passover cake, the oaten and barley bread of Scotland, are of this nature. 2. Leavened bread, mentioned in the Jewish history, has been known to mankind from the earliest age of society. It is thus made: A portion of dough is left till it ferments, or becomes sour. This is mixed with other dough, and causes it to rise; carbonic acid gas is thrown out, a vinous smell is

perceived; and an active fermentation goes on. 3. Bread made with yeast, or family bread, is thus made. To half a bushel of wheat flour add six or eight ounces of salt, a pint of yeast, and six quarts of water. Mix the whole together, and cover it up with a blanket; this operation is called setting the sponge: flour must then be added, and the mass kneaded till it attain a proper consistency. It must then stand for four or five hours, till it rises properly, and afterwards you put it into the oven.

A sack of flour contains about 280 lbs. and will make eighty quarter loaves, allowing three and a half pounds of flour for each. Before the loaf goes into the oven it weighs 4 lbs. 15 oz. but loses nine or ten ounces in baking. In each loaf bakers usually put two ounces of alum, though this is prohibited by law. The alum binds the bread, and makes it more compact, but then it is less wholesome; and it also whitens old flour. Besides the bread just described, there are wheaten and household bread. The former is made of flour, with a mixture of the finer bran; the latter of the whole substance of the grain, without either taking out the coarse bran or the fine flour.

French bread is made by adding ten eggs, and a pound and a half of fresh butter, and as much yeast, to half a bushel of fine flour. The whole mass is tempered with new milk, warmed pretty hot; after being allowed half an hour to rise, it is made into loaves, or rolls, and is washed over with an egg beaten with milk; the oven is of a gentle heat. Bread is highly nutritious. And since, among the animal fluids the saliva is essentially necessary, dry food should be used as a stimulus to draw it forth; thence we eat bread with meat. Bread blends the oil and water of food in the stomach, which it stimulates; and it is peculiarly proper for that purpose, being bulky without too much solidity, and firm without difficulty of solution.

**BREAKWATER**, a sort of small buoy fastened to a large one, when the buoy-rope of the latter is not long enough to reach to the surface of the water; and thereby to shew where the large buoy swims. Breakwater signifies also the hull of an old ship sunk at the entrance of a small harbour, to break off or diminish the force of the waves as they advance towards the vessels moored within. The great Breakwater across the bay of Plymouth, which has been going on for years, and is not yet finished, is the greatest of the kind ever undertaken in the kingdom. The exposed situation of the sound has been long and severely felt as an extreme inconvenience in the harbour, and it was at last determined to oppose, if possible, some barrier to the heavy swell which is here almost continually rolling in from the Atlantic. The plan at last adopted, with the advice of the most experienced engineers, men of science, and naval officers, was, to construct at St. Carlos rocks, about three miles south of Plymouth, a mole, or vast heap of stones, in the middle of the sound, stretching across its entrance, occupying nearly half of its width, and leaving a free passage for vessels, both on the eastern and western shores. The whole expense was estimated at £1,171,100, viz. £1,051,200 for the mole or breakwater, and £119,900 for a pier along the top, with light-houses. It was proposed, that the breakwater should begin 360 feet on the eastward of St. Carlos rocks, and extend 1800 feet west of the Shovel rock; the whole length to be 1700 yards, or very nearly a mile, 4000 feet in the middle being quite straight, and the two extremities having a slope up the sound. It was estimated, that 2,000,000 tons of stone would be required to finish it; and it was advised to heap them promiscuously together in large blocks, not less than  $1\frac{1}{2}$  or 2 tons weight each, leaving them to find their own base and position. Where the water was 30 feet deep, the dimensions of the breakwater were to be 40 feet high, 30 feet across the top, and 210 feet wide at the foundation. The work was begun in 1812; the first stone was sunk on the 12th of August; and on the 31st March, 1813, the building began to make its appearance above the surface of low water at spring tides. The stones were quarried from a rock of limestone or gray marble, purchased from the Duke of Bedford for £10,000, and situated on the eastern shore of Catwater. More than fifty vessels, of peculiar construction, were employed in carrying the stones to the work, many of which were five tons and upwards each. On the whole, this great work has been conducted with much skill and surprising despatch, and the result has fully answered the ex-

pectations of its projectors. At the end of the second year, the swell was so much broken, that ships of all sizes ran in, and anchored with confidence behind the breakwater. Since that time 200 sail of vessels of every description have here found shelter, and 25 or 30 sail of the line may now ride here at all times, in security. The Eddystone lighthouse is an important appendage to the harbour, without which the entrance to the harbour would be extremely dangerous. See **EDDYSTONE**.

**BREAMING**, burning off the filth, such as grass, ooze, shells, or sea-weed, from the ship's bottom, which it has contracted by lying long in harbour; it is performed by holding kindled furze, faggots, or reeds, to the bottom, which, by melting the pitch that formerly covered it, loosens whatever filth may have adhered to the planks; the bottom is then covered anew with a composition of sulphur, tallow, &c. which not only makes it smooth and slippery, so as to divide the fluid more readily, but also poisons and destroys those worms which eat through the planks in the course of a voyage. This operation may be performed either by laying the ship aground after the tide has ebbed from her, or by docking, or careening.

**BREWING**. Brewing is a very ancient domestic art. Before the malt is used it must be bruised between rollers; and soft water is used for mashing and fermentation. The first step in brewing is mashing. This is done in a tub furnished with a false bottom, pierced with holes, and moveable, or fixed a few inches above the real bottom. There are two side-openings between the two; to one is fixed a pipe to convey water into the tun, and the other is used for drawing the liquor out. The malt is to be strewed over the false bottom, and a proper quantity of water let in from the upper copper; after which, the mass is beaten by poles, or a machine like a rake or harrow, and moveable on a perpendicular beam, with transverse arms for the rakes. When the mashing is completed, the tun is covered to prevent the escape of the heat, and the whole is suffered to stand, that the insoluble parts may separate from the liquor; the side-hole is then opened, and the clear wort discharged into the lower copper. The most eligible temperature in mashing is from 185 to 190 degrees, but for the first mashing the heat of the water must be less, and so in proportion to the dark colour of the malt.

The wort of the first mashing is always the richest in saccharine matter; but to exhaust the malt, a second and third mashing are requisite.\* Thirty gallons may be drawn from each bushel of malt, for sound small beer; six and a half gallons only for strong ale. Every bushel of malt absorbs, or retains, about three and a half gallons of water. The next process is boiling and hopping; if only one kind of liquor is to be made, the produce of the three mashings should be mixed; if both ale and table-beer are required, the wort of the first, or first and second mashings, is for the ale, and the remainder for the beer. The wort intended for the same liquor, after it comes from the tun, is put into the lower copper, and mixed with a proportion of hops; and the better the wort, the greater the quantity of hops will be wanted. Hops contain gallic acid and tanning matter, and deprive the sweet wort of the mucilage, which occasions the beer to keep without turning sour. After the hops have been mixed with the wort in the copper, the liquor is made to boil as fast as possible, when it is discharged into shallow tubs, called coolers, where it remains till it is cool enough to undergo fermentation.

From the coolers the liquor is transferred to the working tun, and with it is mixed a gallon of yeast to four barrels of beer. In four or five hours the fermentation commences, but it requires from 18 to 48 hours before the wort is fit to be barrelled. The fermentation still goes on in the barrels, and in a few days a copious discharge of yeast takes place from the bung-hole, and the greater portion of gluten is disengaged. In brewing, the gluten is not wanted, but in bread is indispensable, and alone renders it fit for use. Care must be taken to fill up the barrel every day with fresh liquor; this discharge lessens daily, and ends entirely in about a week, when the bung-hole is closed, and the liquor is fit for use, after standing

\* Brewers use a sacchrometer to ascertain the goodness of the wort. This instrument is a kind of hydrometer, and shews the specific gravity of the wort, rather than the exact quantity of saccharine matter contained in it.

from a fortnight to three months, according to its strength, and the temperature at which it has been fermented. The fining of the beer is done by the use of isinglass. But drugs are sometimes used, to give a narcotic and stupefying power to the beer.

**ALE**, a fermented liquor extracted from malt, has a less proportion of hops than beer. It was first made in Egypt as a substitute for wine, and was a favourite drink with the Anglo-Saxons and Danes. Pale ale is accounted more wholesome than brown ale, because it is brewed from malt slightly roasted, while the latter is made of drier malt.

To make malt, barley is steeped in cold water, not less than 40 hours. When it is sufficiently steeped, the water is drained off, and the barley spread upon the malt floor, where it is formed into a rectangular heap, about 16 inches deep. In this state it remains about 26 hours. It is then turned with wooden shovels, and diminished in depth: this is repeated twice or thrice a day, and the grain is constantly spread, till its depth does not exceed a few inches. On the couch it absorbs oxygen from the atmosphere, which it converts into carbonic acid; the temperature gradually increases, and in four days the grain, now ten degrees hotter than the atmosphere, becomes moist, and exhales an agreeable odour: this is termed the sweating. The maltster must keep the temperature from becoming excessive, by turning. At the period of sweating, the roots of the grains appear. In one day after the sprouting of the roots, the rudiments of the future stem, called the acrospire, may be seen to lengthen. As it shoots along the grain, the mealy part undergoes a considerable change: the glutinous and mucilaginous matter is taken up and removed, the colour becomes white, and the texture so loose that it crumbles to powder between the fingers. When the acrospire has come nearly to the end of the seed, the process is stopped by drying the malt upon a kiln. It is then cleaned. When the grain is dried gradually, or in the sun, it is called air-dried malt; or when quickly, by the heat of a stove, kiln-dried; the latter being charred partially, is brown, more or less intense, and contains less fermentable matter than the air-dried, or pale malt. Burnt sugar is frequently used to colour beer.

**BRIDGE**, an artificial mode of conveyance from one part of space to another, the intermediate part being either impassable, or difficult, or otherwise of inconvenient access. Among the ancients, the Greeks borrowed, with their science, their knowledge of architecture, and consequently of bridge-making, from the Asiatics; and of these last, the Chinese attained a degree of perfection which neither Greece nor Rome could boast. From time immemorial, chain bridges have passed from acclivity to acclivity, a distance in some instances of 600 feet, the height of the arch being 750 feet; and this in one span!

The bridge (of wood or boats) that Darius built over the Propontis, or the Dardanelles, to pass from Asia into Europe, surpasses all the modern military bridges. But this is outdone by the bridge of Trajan over the Danube, which one cannot sufficiently admire; for though all the works of this emperor were magnificent, yet this structure, 4770 feet long, supported by twenty piers of square stone, each pier 150 feet high above the foundation, 60 feet in breadth, and 170 feet from each other, does equal honour to the wise policy of the Roman, and his eastern architect, Apollodorus of Damascus.

Among the moderns, Belidor, an engineer, directs that the piers be one-fifth, or at least one-sixth, of the opening; and the arch stones  $\frac{1}{14}$ th part of the opening: in general, that the pier ought to be of that strength, that it will support its arch as an abutment; which, by practice, he finds to be one-fifth or one-sixth; but gives as a rule, one-sixth and two feet more. For

example, an arch of 36 feet should have a pier of  $\frac{36}{6} + 2 =$

8 feet. In an arch of 72 he makes the pier 14 feet, viz. two feet more than one-sixth.

Gautier, another engineer, differs only from Belidor as to the length of the arch stones; which in arches of 24 feet ought to be 2 feet; if 45, 3 feet; if 60, 4 feet; if 75, 5 feet; if 96, 6 feet, when the stone is of a durable material; but of greater dimensions, when the stone is soft, and easily decomposed:

and an arch stone of 6 feet, of durable material, will suffice for an arch of 150, or even 200 feet. See, in the sequel, *A Table for the Thickness of Bridges.*

**London Bridge**, (see Plate, *Bridges*), planned by Peter of Colchurh, a priest, has its piers much stronger, being more than half the opening; the piers being from 25 to 34 feet, 18 in number, the width of the river being only 900 feet. This bridge is now being supplanted by a more capacious structure, which has this year, 1824, been begun to be built; and of which we shall speak in the close of this article.

The piers of **Westminster Bridge**, (see Plate, *Bridges*), are 17 feet, the breadth of the river 1223 feet, the arches semicircular; the spring commencing about two feet above low-water mark. There are thirteen large and two smaller arches; the centre arch is 76 feet span, and the others decrease on each side by four feet. The passage for carriages is of very difficult ascent, the rise being 30 feet in a distance of 611.5 feet. The whole width is 44 feet, and ledges, balustrades, and semi-octagon recesses, or towers, with the well-paved footpath, give this bridge an elegant appearance.

**Blackfriars' Bridge**, (see Plate, *Bridges*), has elliptical arches, and no precaution was neglected that could contribute to its strength, or give addition to its elegance. In the middle arch, which is of 100 feet span, the flat part of the arch is described with a radius of about 57 feet; the lesser circles on either side being  $35\frac{1}{2}$ , or 36 nearly. This small arch is continued below its diameter, till its chord, as in the annexed figures, become 16 feet nearly, and its versed sine 5 feet nearly, which gives it the degree of novelty alluded to; and which is far from being disagreeable to the eye. The shoulders are compactly filled with rubble work, the bed of each row tending to the centre of the arch. To the height to which the arch can be raised without a supporting frame, an inverted semicircle is drawn, the convexity of

the arch resting upon this rubble work, which is formed of Kentish rag; but other hard stone will equally well answer this purpose, as that cannot be every where procured. The inverted arch answers two purposes; it prevents this rubble being raised by any lateral pressure, and makes those parts of the arch which form the greatest lateral pressure, abut upon each other: hence there is little or no lateral pressure upon the pier.

The bridge of Burton-on-Trent is the longest in Britain, being 1545 feet, supported on 34 arches: the most stupendous in Europe, that over the Tave in Glamorganshire, consisting of only one arch, the segment of a circle whose diameter is 175 feet; the chord of the segment, or span of the arch, 140 feet, the height or vertical sine 35 feet; the abutments 32 feet: the architect was William Edward, a country mason: it was built in 1756.

The Rialto at Venice, built by Michael Angelo, is reckoned a masterpiece of art, on account of its flatness and extent, being  $98\frac{1}{2}$  feet span, and 23 feet only above the water; but this is far outdone by many bridges of modern erection.

**Wooden Bridges.** Where stone bridges cannot be constructed, on account of expense, or other causes, very durable ones may be formed of wood: all the parts ought to press on one another like the arch of a stone bridge; and thus, instead of being weakened by great weights passing over them, they will become the stronger. How this is to be effected, will be best understood from the annexed figure.

The *Swiss Bridge*, (as represented in the following figure,) a rude composition of trees unhewn, and covered with rushes or boards, serves very well for small streams, canals, &c. in

gentlemen's parks, &c. This may be improved by the addition of a rustic balustrade, in the following style.

The *Tied-Plank Bridge*, (as in the annexed figure,) is formed by fixing the ends of two or more planks in two heads of iron, *a, a*, and then connecting them by wrought iron rods, *b, b*, fixed

to the heads in the manner of a bow string. A very slight bridge, thus formed, acts both by tenacity and gravity. Thus, when the bridge is but lightly loaded, the particles of the boards are not moved, but merely pressed on, and, therefore, the arched part may be said to act by gravity, while this pressure, being propagated to the abutments, these are held in equilibrium by the iron rods acting by their tenacity. On the other hand, when a bridge of this description is heavily loaded, the arch will bend downwards, or yield in some places, and rise in others; in which case the whole will act by tenacity.

A very light and strong Bridge may be formed by screwing together thin boards in the form of a segment, or by screwing together a system of triangles of timber, as in the following figure. These triangles being equilateral, become in effect so many parts of hexagonal figures, which may be circumscribed by a circle, and thence carried to any extent, though, in the construction, the whole may act more by tenacity than by pressure.

### Light Bridge.

For broad sluggish rivers, swampy ground, &c. such a bridge will do very well, but it is inferior perhaps to the following

### Strong Bridge.

The *Boat Bridge*, as here represented, may be worked by a mechanical power, as the wheel and pinion, or by means of a cylinder and rope *B*, and machinery fixed in a box *C*, and

connected with the rope *D*, the vehicle may be moved from one side of a stream to the other, by merely turning the winch *E*. A contrivance of this kind was devised by Repton, for passing a piece of water in the park of Holkham Hall, Norfolk, the estate of T. W. Coke, Esq.

The *Flying Boat*, as represented in the annexed figure, with the deck arranged as part of the gravel walk, which approaches the edge of the water, derives its motion from the obliquity of its sides to the direction of the current, which must be kept up by the use of a rudder. The force of the stream is at a maximum when the angle formed by it and the side of the boat, is  $54^{\circ} 44'$ . The boat *a* must be anchored to a post *b*, fixed in the middle of the river, and the longer the cable *c*, the manoeuvre will be the more easily executed, provided the movement is not made in a greater arc than  $90^{\circ}$ . The same purpose may be effected by a triangular raft, without the help of a rudder.

The *Flying Bridge* may be formed of several, or indeed of many boats, joined together and floored with substantial planks, surrounded with a rail or balustrade; and according to its breadth it may have one mast, or two masts, to support a rope at a proper height; one end may turn round a windlass, the other may be fastened to an anchor in mid stream, and may be kept aloft by buoys. As in the former case, the bridge is worked by one rudder, if there is one boat; if more boats, then

back may have a rudder, the tillers of all the rudders moving at the same angle. As the stream is narrow or wide, the suspension rope may be shortened or lengthened by the windlass. Such bridges will ferry over cavalry or infantry; but to become defensible by mutual support and augmented strength, several such bridges, at convenient distances, are launched and moored. A B, C D, (in the following figure,) are two long boats which support the bridge; G H, K L, two masts joined

at their tops by traverse beams, and a central arch supported in a vertical position, by two pair of shrouds and two chains, L N and H R. M is a horse, or cross piece, upon which the cable M F, e f, rests: the use of this has been explained above. The buoys are e, f. E windlass, a, b, rudders. A B, C D, two portions of bridges of boats fastened to the banks on each side of the stream, and between which the bridge traverses. The annexed figure is a ground plan of the same bridge. K, Q,

the mast holes; E, windlass; N, N, pumps; P, P, capstans. Fig. 1, a lateral elevation of the same; b, the rudder; E, the

View Fore and Aft.

windlass; M, the horse; E, N, H, F, the cable. Fig. 2, is an elevation of the hinder part of the bridge or stern; a, b, the two boats; Q H, K L, the two masts; H L, the upper traverse beam; p q, the lower traverse beam, over which the cable passes, and occasionally slides from one mast to the other; and must on that account be kept well greased. p h, g g, shrouds; M the cross piece over which the cable passes to the windlass.

The *Bushen Bridge*, made of bundles of rushes, serves to afford a passage over marshy ground. And bridges of casks, bottles, bladders, and buoys made of skins, do well for transporting individuals, or even troops, as portable machines.

The *Draw Bridge*, made after the manner of a float, to draw up or let down, as occasions serve, before the gate of a town or castle, may be made after several different ways; but the most common are made with plyers twice the length of the gate, and a foot diameter. The inner space is traversed with a cross, which serves for a counterpoise, and the chains which hang from the extremities of the plyers, to lift up or let down the bridge, are of iron or brass. Such bridges we have seen at Stirling and Edinburgh castles, at the Tower of London, at the castle of Vincennes, and many other regularly fortified places. In navigable rivers it is sometimes necessary to make the middle arch of bridges with two moveable platforms, to be raised occasionally, in order to let the masts and rigging of ships pass through this kind of drawbridge. A B (in the following figure) represents the middle of the arch; A L and B L the two piers that support the drawbridge, N O, one of the platforms of which is raised and the other let down, having the beam P Q

for its piler. To N O are suspended two moveable braces, E H, E H, which resting on the support E, press against the bracket M, and thereby strengthen the draw bridge. These braces are conducted to the rest by means of the weight S pulling the chain S L F.

It will now be necessary to proceed with those details upon which the practical construction of bridges depends; and we will therefore lay down Belidor's Table for the thickness of their piers, agreeably to what has been said above, on the relative proportions between the span of the arch and the thickness and height of the piers.

The first horizontal line expresses the height of the piers in feet, from 6 to 24 feet, each increasing by 3. The first vertical column, the width of the arches from 20 to 100 feet, for every five feet. The other columns express the thickness of piers in feet and decimals, according to the respective height at the head of the columns, and the width of the arch against it in the first column. Thus, e. g. let the width of the arch be 60 feet, and the height of the piers 12, then the number 12.718 under 12, and against 60, expresses the thickness of the piers, i. e. 12 feet 8 inches  $\frac{11}{10}$ ths. The length of the key-stone in an arch of 30 feet wide, is 2 feet; 3, 4, 5, 6 feet in an arch of 45, 60, 75, 90.

As this table contains the thickness of the piers in respect to arches that are commonly used in practice, we imagine it would be needless to carry on the table further; because the difference between the thickness of the piers of any two con-

iguous arches being but small, those between any two marked here may be made equal to half the sum of the next below and above it; thus, the thickness of the piers of an arch 52 or 53 feet wide, is nearly equal to 10·242, half the sum of the thicknesses 9·085 and 10·64, of the arches 50 and 55 feet wide, when the height of the piers is 6 feet.

TABLE containing the Thickness of Piers of Bridges.

|     | 6      | 9      | 12     | 15     | 18     | 21     | 24     |
|-----|--------|--------|--------|--------|--------|--------|--------|
| 20  | 4·574  | 4·918  | 6·165  | 5·350  | 5·492  | 5·610  | 5·689  |
| 25  | 5·490  | 5·913  | 6·216  | 6·455  | 6·645  | 6·801  | 7·930  |
| 30  | 6·386  | 6·816  | 7·225  | 7·513  | 7·746  | 7·939  | 8·102  |
| 35  | 7·258  | 7·788  | 8·200  | 8·532  | 8·807  | 9·037  | 9·233  |
| 40  | 8·404  | 8·691  | 9·148  | 9·523  | 9·835  | 10·101 | 10·328 |
| 45  | 8·965  | 9·579  | 10·077 | 10·489 | 10·817 | 11·316 | 11·394 |
| 50  | 9·805  | 10·454 | 10·987 | 11·435 | 11·817 | 12·148 | 12·234 |
| 55  | 10·640 | 11·245 | 11·882 | 12·364 | 13·019 | 13·149 | 13·218 |
| 60  | 11·400 | 12·110 | 12·718 | 13·218 | 13·723 | 14·109 | 14·314 |
| 65  | 12·265 | 13·025 | 13·648 | 14·185 | 14·654 | 15·082 | 15·435 |
| 70  | 13·114 | 13·869 | 14·517 | 15·049 | 15·573 | 16·011 | 16·400 |
| 75  | 14·000 | 14·705 | 15·336 | 15·965 | 16·480 | 16·940 | 17·354 |
| 80  | 14·747 | 15·542 | 16·234 | 16·842 | 17·381 | 17·864 | 18·296 |
| 85  | 15·513 | 16·328 | 17·041 | 17·674 | 18·237 | 18·742 | 19·198 |
| 90  | 16·373 | 17·201 | 17·429 | 18·178 | 19·257 | 19·679 | 20·132 |
| 95  | 17·184 | 17·826 | 18·771 | 19·438 | 20·036 | 20·577 | 21·008 |
| 100 | 17·991 | 18·848 | 19·620 | 20·293 | 20·908 | 21·468 | 21·978 |

Rectangular piers are seldom used but in bridges over small rivers. In all other cases, they project beyond the bridge by a triangular prism, which presents an edge or an angle to the current, in order to divide the water more easily, and to prevent ice and other matters, that float, from sheltering there, as well as vessels from running foul against them. That edge is terminated by the adjacent faces at right angles to each other at Westminster bridge, and makes an acute angle at the Pont Royal of Paris, of about 60 degrees; but of late, the French terminate this angle by two cylindric surfaces, whose bases are arcs of 60° in all their new bridges.

*Slope of the Bridge on each side, and Width.*—When the banks of the rivers are high, the bridge is level above, and all the arches of an equal width; but where they are low, or for the sake of navigation, a large arch is made in the middle of the stream, and the bridge is higher in the middle than at the ends; the slope easy and gradual on both sides, so as to form one continued curve line. The descent of that slope may be one-fiftieth part of the length.

The width allowed to small bridges is 30 feet; but in large ones, near great towns, 30 feet are allowed clear for horses and carriages, besides a pathway on each side for foot passengers, from 6 to 9 feet broad, raised about a foot above the carriage road; the parapet walls on each side are about 18 inches thick, and 4 feet high, and generally project over the bridge with a cornice underneath. Sometimes balustrades of stone or iron are placed upon the parapet, as at Westminster and Blackfriars' bridges; but this is only practised in bridges of a great length, and near the capital of a country. The ends of bridges, open from the middle of the two large arches with two

wings, making an angle of 45 degrees with the vest, in order to make their entrance more free and easy. These wings are supported by the same arches of the bridge next to them, being continued in the manner of an arch, of which one pier is much longer than the other.

*The Methods of Laying the Foundation.*—Laying the foundation of the pier is the most difficult part of the whole work, except when the depth of the water does not exceed 6 or 8 feet. In shallow water, one of the abutments, with the adjacent piers, is enclosed by a dike of a sufficient width for the work, and room for the workmen. This dam is made by driving a double row of piles, whose distance is equal to the depth of water, and the piles in each row are 3 feet from each other. They are fastened together on the outside by bonds of 6 by 4 inches thick. This done, frames about 9 feet wide are placed on the inside, to receive the boards which are to form the enclosure. The two uprights of these frames are two boards of an inch and a half thick, sharpened below, to be driven into the ground as deep as necessary; then the boards themselves are likewise driven in till they reach the firm ground underneath. Between every two piles, tie-beams are fixed to the ends of the piles, to strengthen the inside wall, and fasten it to the outside one; these tie-beams are let into the bonds, and bolted to the adjacent piles. The bottom is then cleared from the loose sand and gravel, by a machine like that used by ballast-heavers, and then well prepared clay is rammed into this coffer very tight and firm, to prevent the water from oozing through. Sometimes these enclosures are made with piles only, driven close to each other; at others, the piles are notched or dove-tailed one into the other; but the most usual method is to drive piles with grooves in them, 5 or 6 feet distant from each other, and boards are let down between them in these grooves.

Pumps and other engines are now used to draw the water out of the dams or enclosures, till they become quite dry; then the foundation is dug, and the stones are laid with the usual precautions, observing to keep some of the engines always standing, to draw off the water that may ooze through the coffer work. The foundation being cleared, a course of stone is laid on the outside all round, with the largest stretchers and headers that can be had, and the inside filled with ashlers well jointed, the whole laid in terrass mortar; and some cramps are also used to fasten the facings with the inside. The same manner is to be observed throughout all the courses, to the height of low-water mark; after which, the facings alone are laid in terrass mortar, and the inside with the best of the common sort. When the foundation has been raised to the height of low-water mark, or to the height where the arches begin, then the shaft or middle wall is to be carried up nearly to the height of the arches, and there left standing till all the piers are finished, in order that the masonry may be sufficiently dry and settled before the arches are begun.

*The proper Form of the Base.*—As the piers terminate generally with an arch at each end, it is usual to lay the foundation in the same manner; which is not so well as to continue the base rectangular quite to the ends of the piers, and as high as low-water mark, both because the foundation becomes then so much broader, and also because the water will not be able to get under it; for when the current sets against a flat surface, it drives the sand and mud against it, so as to cover it entirely, whereas if a sharp edge be presented to the stream, it carries every thing away, and exposes the foundation to the continual action of the water, which in course of time must destroy it.

After the intervals between the arches are filled up with stones, laid in a regular manner, without mortar, and the gravel is laid over them; two drains or gutters are made lengthwise over the bridge, one on each side next to the foot-path, about six feet wide and a foot deep, which being filled with small pebble-stones, serve to carry off the rain water that falls on the bridge, and to prevent its filtering through the joints of the arches, as often happens.

*Method of Building with Coffers, as was practised at Westminster Bridge,* is to build with coffers, when it is preferable, from the depth of water being 6 feet at a medium when lowest, and the tide rises about 10 feet at a medium also, so that the greatest depth of water is about 16 feet. At the place where

one of the piers at the middle or great arch was to be, the workmen drove piles of about 13 or 14 inches square, and 34 feet long, shod with iron, so as to enter into the gravel with more ease, and hooped above, to prevent their splitting in driving them home. These piles were driven from 13 to 14 feet below the bed of the river, and 7 feet distant from each other, parallel to the short ends of the pier, and about 30 feet distant from them. The number of these piles was 34, and their intent was, to prevent any vessels or barges from approaching the work; and in order to hinder boats from passing between them, booms were placed so as to rise and fall with the water.

At this stage of the work, the ballast-men dug the foundation under the water, of about 6 feet deep, and 5 wider all round than the intended coffer was to be, with an easy slope, to prevent the ground from falling in. In order to prevent the current from washing the sand into the pit, short grooved piles were driven before the two ends, and part of the sides, about 4 feet higher than low-water mark, and 15 feet distant from the coffer: between these piles, rows of boards were let into the grooves down to the bed of the river, and fixed there.

The bottom of the coffer was made of a strong grating, consisting of two rows of large timbers, the one longways, and the other crossways, bolted together with wooden trunnels ten feet wider than the intended foundation. The sides of the coffer were made with fir timbers laid horizontally close one over another, pinned with oaken trunnels, and framed together at the corners, excepting at the two protruding angles, where they were secured with iron, so that the one half might be loosened from the other, if it should be thought necessary: these sides were lined on the inside, as well as on the outside, with three-inch planks placed vertically; the thickness of those sides was 18 inches at the bottom, reduced to 15 above, and they were 16 feet high; besides, knee-timbers were bolted at the angles, to secure them in the strongest manner. The sides were fastened to the bottom by 28 pieces of timber on the outside, and 18 within, called *straps*, about 8 inches broad and 3 or 4 inches thick, reaching and lapping over the ends of the sides. The lower part of these straps had one side cut dove-tail fashion, to fit mortises made near the edge of the bottom, and were kept in their places by iron wedges; which being driven out when the sides were taken away, gave liberty to clear the straps from the mortises.

Before the coffer was launched, the foundation was examined, to know whether it was level; for which purpose several gauges were made, each of which consisted of a stone of about 15 inches square and 3 thick, with a wooden pole in the middle, of about 18 feet long. The foundation being levelled, and the coffer fixed directly over the place with cables fastened to the adjacent piles, the masons laid the first course of stones for the foundation within it; which being finished, a sluice made near the side was opened at low water, on which the coffer sunk to the bottom; and if it did not set level, the sluice was shut, and the water pumped out, so as to make it float till the foundation was levelled: then the masons cramped the stones of the first course, and laid a second, which being likewise cramped, a third course was laid: then the sluice being opened again, proper care was taken that the coffer should settle in its due place. The stone work being thus raised to within two feet of the common low-water mark, about two hours before low water the sluice was shut, and the water pumped out, so far as that the masons could lay the next course of stone, which they continued to do, till the water was risen so high as to make it unsafe to proceed any further; then they left off the work, and opened the sluice to let in the water. Thus they continued to work night and day, at low water, till they had carried their work some feet higher than the low-water mark; after this, the sides of the coffer were loosened from the bottom, which made them float, and then were carried ashore to be fixed to another bottom, in order to serve for another pier. It must be observed, that the coffer being no higher than 16 feet, which is equal to the greatest depth of water, and the foundation being 6 feet under the bed of the river, the coffer was therefore 6 feet under water when the tide was in; but being loaded with three courses of stones, and well secured with ropes fastened to the piles, it could not

move from its place. By making it no higher, much labour and expense were saved; yet it answered the intent fully as well as if it had been high enough to reach above the highest flood.

The pier being thus carried on above low-water mark, the masons finished the rest of it during the intervals of the tides in the usual way; and after all the piers and abutments were finished in like manner, the arches were begun and completed as mentioned before. The whole bridge was built in about seven years, without any accidents happening either in the work, or to the workmen.

*Materials employed.*—All the piers were built with solid Portland stone, some of which weighed four tons. The arch stones were likewise of the same sort; but the rest of the masonry was finished with Kentish rag-stones, and the paths for foot passengers were paved with Purbee, which is the hardest stone to be had in England, except granite, called otherwise Plymouth marble.

*This Method sometimes impracticable.*—This method cannot be used in many cases; as where the foundation is so bad as not to be depended upon without being piled, or the depth of water is very great, with a strong current and no tide. For if piles are used, it will be impossible to cut them off in the same level five or six feet below the bed of the river; and if this is not done, the grating or bottom of the coffer will not be equally supported, whereby the foundation becomes precarious. In a great depth of water, having a strong current and no tide, the coffer must reach above the water, which makes this process expensive, unwieldy, and difficult of execution; so that there is no probability of using it in such a case.

*The Russian Method.*—In some cases, where there is great depth of water, and the bed of the river tolerably level, or where it can be made so by any contrivance, a strong frame of timber, four times as large as the base of the piers, may be let down with stones upon it, round the edges, to make it sink. After fixing it level, piles must be driven about it to keep it in its place, and the foundation laid in coffer as before, which are kept steady by ropes tied to the piles. This method has frequently been practised in Russia; and though the bed of the river is not solid, yet such a grating, when once settled with the weight of the pier upon it, will be as firm as if piles had been driven under the foundation; but to prevent the water from gulling under the foundation, and to secure it against all accidents, a row of dove-tail piles must be driven quite round the grating. This precaution being taken, the foundation will be as secure as any that can be made.

*The French Method.*—The French engineers use another method in raising the foundations of masonry under water, which is, to drive a row of piles round the intended place, nearer to, or farther from, each other, according as the water is more deep or shallow. These piles being strongly bound together in several places with horizontal tie-beams, support a row of dove-tail piles driven within them: when this is done, and all are screwed according to the nature of the situation and circumstances, the foundation is dug by a machine with scoops, invented for that purpose, until the workmen come to a solid bed of gravel or clay; or if the bed of the river is of a soft consistence to a great depth, it is dug about six feet, and a grating of timber is laid upon it, which is well screwed with piles driven into the opposite corners of each square.

When the foundation is thus prepared, the masons make a mortar called *beton*, which consists of twelve parts of pozzolano or Dutch terras, six of good sand, nine of unslaked lime, thirteen of stone splinters not exceeding the bigness of an egg, and three parts of tile dust, or cinders, or else scales of forge iron: this being well worked together, must stand 24 hours, or till it becomes so hard as not to be separated without a pick-axe. This mortar being thus prepared, they throw into the coffer a bed of rubble stones, not very large, and spread them all over the bottom as nearly level as they can; they then sink a box full of this hard mortar broken into pieces, till it comes within a little of the bottom; the box is so contrived as to be overset or turned upside down at any depth; the pieces of mortar now soften, and so fill up the vacant spaces between the stones; by these means they sink as much of it as will form a bed of about 12 inches deep all over; then they throw in

another bed of stone, and continue alternately to throw one of mortar and one of stone, till the work approaches the surface of the water, where it is levelled, and then the rest is finished with stones in the usual manner. A coffer containing 27 cubic feet of masonry made of this mortar, and sunk into the sea, was there left standing for two months, and when it was taken out again, it was harder than the stone itself.

The usual way in which the foundations of Waterloo Bridge, Southwark Bridge, and Vauxhall Bridge, have been laid, was by driving piles of Memel logs, 14 or 15 inches square, for the construction of the coffer, which was cleared of water by means of pumps, and the work proceeded much in the same way as mentioned above.

**GEOMETRICAL Construction of Bridges.**—Bridges constructed with circular or elliptical arches, being the most common, we now proceed to lay down a theory for their construction, founded on philosophical principles, which, by our mode of explanation, will be understood by the mechanic, and cannot be unworthy the attention of the man of science.

All bodies in the earth tend to the centre of the globe, unless prevented by some force that resists their obedience to the universal law of gravity, and changes their direction. If we attend particularly to one body, having all its parts tending equally to the centre of the earth, and supported in that position, it will retain its position. If we suppose another body to press upon it, so as to change that position, which it has on its support, or force away its support, in whole, or in such part, that a greater part of the body has a tendency to the centre, more than it has to its support, it will fall towards the earth in a direction to its centre.

Let A B, as in the annexed figure, be two supports, suppose one foot square, 5 feet high, or any other height, standing

*Egyptian Bridge.*

perpendicularly, and let a piece of the same dimensions, wood or stone, F, three feet in length, be placed across in equilibrio; the perpendicular support is not pressed by this weight, but in the perpendicular direction. If a second piece, of 5 feet, is laid upon the 3 feet piece, in the same way, projecting 1 foot on each side, they will still remain in equilibrio, and so on till the two bodies upon the two uprights meet one another, as in the figure, the planks or logs D D meet in E, without affecting the supports, except in the perpendicular direction. The equilibrium being preserved, no force imposed will make the supports give way, that will not separate the particles of matter, or break its contexture. Neither will any weight push it over, that is not greater than the perpendicular pressure; for action and reaction are equal, acting in contrary directions. The force then that it will support before it yield, is equal to the number of square feet that rests on its surface, and turns upon the angular point F. Now, suppose this operation continued the whole length of the bridge, and the whole level blocks in contact with one another, received by the abutments, or landstools, the bridge will support any weight that the strength of those blocks could sustain, and the abutments react upon. This is the genuine Egyptian arch, not elegant, but strong, as each block is supported one foot distant, and the upper ones in contact with one another, only react by their own strength, at one foot distant, without support; and by the reaction of the land abutments cannot yield to give any lateral pressure upon the pier.

Let us now suppose a semicircle of any other arch described, the superfluous matter is carried off, and the arch remains in strength and beauty. Now, instead of balancing the blocks by counterpoise on each side of the support, let this be taken off, and applied as weights above the pier, being equal in weight to those that form the arch, the equilibrium is still preserved, without any lateral pressure. This may be illustrated by a very simple experiment. Let A, B, C, D, in the annexed figure,

be four blocks; the first, A, a square, which represents the base; if the second, B, a pentagon, inscribed in a circle of the same radius about which the square is described, be placed with one of its angles to the perpendicular edge of the square, a perpendicular falls within the base, and it is therefore firmly supported. Let the hexagon, C, be placed upon one of the sides of the pentagon, the two angles likewise coinciding. In this the perpendicular falls over the base; it will therefore be no longer firmly supported, but will fall, and, if attached to the pentagon, would carry a part of it along with it, except prevented by friction, and consistency of the texture of materials. In this situation let it be retained, till a pentagon is placed on the opposite side of the hexagon; the plumb line, or perpendicular, as it now appears, falls within the base, and will be again supported so as to carry an additional block raised upon it, or require a considerable force to pull it over on that side, to which the hexagon was inclined to fall. The conclusion we would draw from the above, is, that if the column or pier is of such dimensions at top, where the spring of the arch rises, that a weight of such materials as the arch is composed of can be raised, not exceeding the height of the vertex or crown of the arch, as will counterpoise that part of the arch that produces the lateral pressure; then a pier of such dimensions is of sufficient strength to support such an arch, till the other arches are thrown, and the whole made to abut upon columns that will counterpoise the whole with any incumbent weight proposed.

To apply the arches to their piers, and to one another, they should abut upon one another, as in the following figure.

In the next figure, we take a semicircular arch of 75 feet span, or archstone we think of a sufficient strength, at 3 feet length; our pier 6 feet, equal to the two archstones. As every arch can be raised to a certain height, without the support of the centre arch; allowed, to the 30th degree, or one-third of the distance to the crown of the arch, we have divided the quadrant or half of the arch into eighty-three equal parts; and where more than half of the archstone falls over the perpendicular, we consider this as the height, not to be exceeded without support. The weight of matter upon the pier to this height, we compare with the weight of matter from that contained in the archstones, or rather, what breadth of pier will contain a quantity of matter that will counterpoise the weight of the archstones of an arch of given span, and length of archstones to the crown of the arch. In investigations of this kind, recourse is had to trigonometrical calculations, and to algebraic and fluxionary equations. Foreign writers give us rules, collected from such constructions as suited their taste; and most algebraic and fluxionary equations take their data from some bridge, the construction of which pleases the writer, and brings his result agreeable thereto.

Let us consider the archstones as wedges abutting upon one

another, and the whole upon the landstool, or upon the pier of the particular arch, and resisted by pressure, which may be expressed by a line placed at right angles to an archstone, at that part of the arch which rests upon the centre arch; but whose length is not yet determined, but will be determined in the result of our theory, of which every mechanic is able to judge; and which, at the same time, we flatter ourselves the learned will not find cause to challenge.

The thickness of the pier we have taken is,  $A b$ , 6 feet; each division of the arch is equal to 2 feet on the outside, and tends as a wedge to the centre of the circle. The inside measures 1·8 feet, the mean is  $1·9 \times 3$ ; the length of the stone is 5·7 of surface: we suppose it taken 3 feet into the arch, or it is equal to 17·1 solid feet in each of our divisions; the scale is half an inch to 10 feet. The solid measure on the whole is easily found; the  $30^\circ$  is at  $a$ , but the arch will rise without the support of the centre arch to  $c$ . Now, the number of divisions from  $a$  to the centre of the arch, is 22·2; which multiplied by 17·1 solid feet each, is 379·62 solid feet; the pier of 6 feet contains to the height,  $a$ , the surface  $A b d a$ , at a mean, taken as in the table,  $a$  is 72·75, being each 2 feet, is 145·5 superficial feet,  $\times 3$ , the assumed depth is 436·5 solid feet, being fully in equilibrium with the archstones; but as the arch will rise to  $c$ , there is an additional weight of 229·5 solid feet, which will be allowed more than a counterpoise to the pressure of the arch, without any aid from the pier, which has only the perpendicular pressure to support. By this, therefore, is ascertained, the counterpoise which will support this arch until the other arches are raised; which, as they all abut upon one another, the landstool must be made of such strength as to counterpoise the whole. This is ascertained upon the same principle, and leaves no stress upon the piers, but the perpendicular pressure alone. This pier is scarce one-twelfth part of the opening, by which, the river having so free a passage, will affect the bridge by pressure but very little. The above figure is a perspective view of one arch of a bridge, on this construction, with part of an adjoining arch on each side.

But the piers must be made of greater breadth, when the situation of the river, or other circumstances, or when a segment of a circle is made choice of for the ease of the passage, or when economy in the use of materials and mason-work are considered; or the base of the arch, or the surface of the pier, will not admit of mason-work to bear upon the spring of the arch, of such weight as to produce a sufficient counterpoise to the archstones that produce the lateral pressure. If the arch is flatter than that now under consideration, the pier ought to be broader; and this is ascertained in projecting the plan. At the same time, as the fall and destruction of an arch is attended with very great loss in money, time, and materials, by way of precaution, beams may be made to abut upon one another, and upon each pier; and this will be no loss of time or materials either, as it will supply, in part, the support of the centre arches, upon which the arch of the bridge is raised; and it is a precaution used, upon a smaller scale, when, in front walls of houses, the whole is often supported upon arcades of shop doors and windows, many of their piers not exceeding 9 or 10 inches: a cross bar, or piece of wood laid across, to prevent their yielding or losing the perpendicular, till the whole is completed. Now, the pressure upon the arch is not so great as most writers have assigned, that is, to the whole incumbent weight of all the materials above it, together with that of passage. The art of masonry is such, that the beds or rows of stones are so bound one with another, that

each makes a pressure on its contiguous part, so as to form an arch of themselves. We see in well-built walls a vast excavation made in the lower part, or in the middle of the wall, and the upper part of the building not affected. In like manner, the arches being all raised to the height that they can be, without the support of the centre arch, they are completed and filled up to the level of the keystone, but not higher. The arch is properly secured, if the principles of equilibrium, in filling up, are properly attended to; but if one side is overloaded, either in filling up or in building, it must twist the arch, and, if not instantly to break it, must tend to an uncertainty as to its durability.

Among the various writers upon bridges, some prefer the circular arch, both for strength and elegance. Others contend, that it is exceeded in both by the elliptic arch. Others will give the preference to the catenarian arch; and we are told, that the excellency lies on the side of the parabolic curve. We do not think it incumbent on us to combat each of these; neither do we think our readers would thank us for so doing. It may, however, be expected, that we should not pass them entirely unnoticed.

In the first place, then, we are of opinion, that the arch that bears most equally throughout the whole, one part upon another, has the best claim to strength. Our reason is, which we illustrate thus, let  $A B$ ,  $A C$ , be placed as in the annexed figure. Suppose a weight, placed upon them in such a manner as to press equally upon the point  $A$ , the two bodies  $A B$ ,  $A C$ , will in that point support the greatest weight. If the same weight is laid in the middle, between  $A$  and  $C$ , or  $A$  and  $B$ , they will each yield to the pressure; for the weight is not equally divided between them. But if these bodies are so placed, that in every position on which a weight can be applied to them, the weight shall be equally supported by both, we should give this form the preference as to strength; and this is the case with the circle. As to elegance, we know that regularity is a qualification that suits every taste; and here the circle cannot be outvied. It is not, however, without its disadvantages; for with regard to expediency, the semicircular arch is sometimes too high for the situation of some bridges. In this case, the elliptic arch, formed upon the greater axis, offers itself, in point of expediency, and yields not in point of elegance. We are bold enough to assert, that if strength of materials forms its composition, and be properly abutted, it will not yield, in point of strength, in any exigence to which it may be applied. In point of economy, it claims a preference to the semicircular arch.

For our part, we are inclined to own the reasonableness of its claim, and to give it the preference to the segment of a circle, which might perhaps be preferred in point of expediency, as it can be rendered as flat as the ellipse; but its flatness we rather consider as a disadvantage, as in the rise of the water it is apt to choke its course, and overturn it; whereas, the ellipse being nearly formed of two segments of circles of different radii, the smaller arches at its extremity raise more in the perpendicular, and give more scope to the current of the water; and likewise, it does not require a stronger pier than a semicircle of the same diameter. The segment, on the other hand, if flat, requires a stronger pier, and therefore tends more to choke the current of the river, which ought always to be avoided when it can be done.

In the catenarian arch, when a chain or rope is fixed at each end, and allowed to fall down in the middle, the curvature is not equal throughout; and we therefore cannot think it entitled to equal claim with the circle or ellipse. The same objection may, with equal propriety, be made to the parabola. This curve, near its vertex, has almost the property of a circle; but every one who knows a parabola, is convinced how much it deviates from it afterwards, although every where it retains the property of its own curve.

We now take a review of the different bridges we have mentioned, and make some observations upon them. In general, we remark, that all the writers upon this art have formed the abutments of each particular arch, to be placed in the pier below the spring of the arch; on which account, many have constructed their piers of greater strength than necessary; as in that by the Roman emperor Trajan, over the Danube; but being broken down by his successor, to impede the passage of his invaders, we cannot, with certainty, compute the lateral pressure upon the piers.

According to the rules given by Belidor, the breadth of the pier that will form an abutment to an arch of 75 feet span, is 14 feet, if the height at the head of the columns be 6 feet. We have formerly stated, that this arch can be raised to  $c$ , as in the following figure, without applying the centre arch. From

the centre of this archstone we raised a perpendicular  $pg$ , and from the lower part of the archstone drew the line  $fb$  parallel to it: this line,  $fb$ , we supposed to cut the centre of the pier in  $h$ . Suppose Belidor allowed a part of the pier equal to the length of the archstone, which we have in this figure taken at 3 feet, one-twenty-fourth of the opening nearly, viz.  $hb$ ,  $Ah$ , would be allowed for the perpendicular support of the archstones to  $c$ . We find  $hg$  measures five and a half feet, we therefore extend  $hg$  to  $l$ , which is 11 feet, and  $Al$  14 feet, for the breadth of the piers. In place of taking the whole width of the bridge, we take only 3 feet, as formerly. The number of equal divisions from  $c$  to the vertex, or middle of the keystone, is  $20\frac{1}{2}$ ; each of the equal divisions at these breadths contains  $17\cdot1$  solid feet; as by our former measure, which multiplied by  $20\frac{1}{2}$ , is  $350\cdot55$  solid feet. The pier, 14 feet broad by 6 in height, and 3 feet deep, is 252 solid feet: the solid building,  $cfbm$ , being supported in the perpendicular, he considers as a part of his abutment, of which  $fb$  measures 26 feet, by  $cf$  3, and by 3 in depth, is  $234 + 252 = 486$  solid feet, to counterpoise  $350\cdot55$  solid feet, which is amply sufficient. Suppose that the pier is 13 feet, at the above height it contains 234 feet,  $+ 234$  as before,  $= 468$  feet, which, to account for accidents, and from his practice and observation, gives the dimensions of the table rule, which, we suppose, is now fully accounted for. If the height of the pier is more than 6 feet, we add to the breadth of his pier in proportion. When the span is above 80 feet, one-sixth of the opening is sufficient in strength to resist every exigence; but if the arch is a segment, the same rule gives the breadth of the pier rather more than 14 feet. Belidor confines his rule to the semicircular arches. We have already mentioned what we think a proper limitation to his rule for taking the 24th part of the arch for the length of his archstone.

London Old Bridge, executed in stone, under the direction of Peter Colechurch, a priest; was thirty-three years in building, being begun by Henry II. in 1176, and finished by John in 1209. The piers, eighteen in number, are from 25 to 34 feet thick. Peter turned the course of the Thames through Southwark, while he executed an undertaking that choked up the course of the river, from 900 to 194 feet; but as this objection is about to be removed, we need say no more about it.

Westminster Bridge, an elegant and noble fabric, has its pier only 8 feet from the bed of the river. The thickness, for a sufficient counterpoise to the arch, could not exceed 14 feet; but

lately, the architect has given it 17. The arches are semicircular, the middle one being 76 feet span; the ascent one-twentieth part of the half-width of the river, which is here 1223 feet, one half is 621·15, and the rise is  $30\frac{1}{2}$  feet in that extent.

The next we notice, is Blackfriar's, as in the following figure, executed by Mylne, whose ingenuity and ability as an engineer are universally acknowledged. The middle arch is an elliptic span of 100 feet, by which, with other advantages, the passage is rendered more commodious; the ascent more easy than on Westminster Bridge. The quickness of the rise of the arches of the small circles, with the flatness of the large circle, are particularly well adapted to give a more easy passage to

the river, when rising either from a tide or other accidental causes, and renders the choice of the elliptic arch here very judicious. We are likewise much pleased with the ingenuity of the inverted arch, which effectually prevents any rising of the rubble work that fills the interstices between the arches by any pressure whatever; as it abuts upon the archstones at  $E$ , it presses their joints upon one another, in a more effectual manner than perhaps could be accomplished by any other method; but the effect produced by it, and in which we think its excellency mostly consists, is, that it makes the arches, at that point where they produce the greatest lateral pressure, to abut upon one another, and thus take off the lateral pressure from the pier. Had Mylne availed himself of this, his pier would have been at least one half thinner. But in place of this, he has made it at the extremity of the greater axis,  $Aa$ ,  $Bb$ , 19 feet, and increased it in a circular form to 22 feet. Experience has proved, that when the resisting force is placed in the pier, one-fifth of the opening is more than sufficient for supporting this resisting force; therefore the course of the river should not have been contracted from 100 to 70 feet.

The depth of the water, at ordinary tides, is not less than 16 feet; and by the principles of hydrostatics, the pressing force of a solid foot of water, at that depth, is equal to 8500 lbs. which  $\times 30$ , the number of feet contracted, gives 113·8 tons upon the foundation of his pier, far more than was necessary; but this does not at all derogate from the method.

In our drawing of the middle arch, and part of the adjoining arches,  $AB$  is the length of the greater axis of the ellipse, and span of the arch 100 feet;  $f, f$ , the centres of the lesser circles;  $DD$ , the inverted arches abutting upon the archstones  $EE$ ;  $V$ , the vertex or crown of the arch;  $FF$ , the thickness of the pier at the bed of the river;  $Aa$ ,  $Bb$ , the thickness of the pier at the extremity of the greater axis. We have put on the bolting in one of the arches, one with the Kentish rag-stone; the bolts about a cubical foot, sunk half way into each stone; the stones in the pier are bolted with firm oak, of a solid foot, dove-tailed into each stone, which renders the whole pier firm as if one stone.

What has been said on the breadth of piers, renders any observations on the bridge over the Trent at Burton, or the single arch over the Tave, in Glamorganshire, unnecessary; the abutments of the last being on land, the method of obtaining their strength will be pointed out when we speak of the abutments of iron bridges, of which there are now several in England.

The first was that erected over the Severn, near Coalbrookdale, in Shropshire, by Abraham Darley; the iron work was cast at Coalbrookdale in 1779, and consists of one arch of 100 feet 6 inches span. It rises to the height of 45 feet, and consists of ribs, each cast in two pieces, secured at the crown by a cast iron keyplate, and connected horizontally and vertically

by cast iron braces formed with dove-tails and forelocks; the ribs are covered with cast iron plates; the railing is of iron: the weight of the whole is  $387\frac{1}{2}$  tons. The ironwork was executed by Messrs. Wilkinson and Darley, ironmasters; for which they have great credit, being the first instance of that material applied in the bridge way. In 1801 it appeared as perfect as when put up, except what was owing to the failure in the stone abutments, which had occasioned some cracks in some of the small pieces.

The second bridge of this kind, built over the same river at Builthwas, at the expense of the county of Salop, was agreeably to a plan under the direction of Mr. Telford, surveyor of the public works in that county: the iron work was cast at Coalbrookdale in 1795 and 1796. It consists of an arch of 130 feet span; the rise of the arch is 27 feet from the spring to the suffit. The situation of the road here is necessary to be kept low; and the outside ribs rise as high as the tops of the railing, and are connected with the ribs that bear the covering plates, by bars of iron cast with deep stanches close to each other, and forming an arch of themselves; so that the bridge is made, upon the whole, compact and firm: the weight of the whole is 173 tons  $18\frac{1}{2}$  cwt. Some smaller arches, and an aqueduct at Longdon, have been made under Mr. Telford's direction in the same county.

The next, upon a large scale, and made of iron, is that over the river Wear, at Monk-Wearmouth, in the county of Durham. This bridge, as represented in the following figure, is the segment of a circle, whose radius is 443 or 444 feet; the span of the arch, or length of the bridge, is 236 feet; the height of its vertex above the spring of the arch is 34 feet; and height above the surface of the water 60 feet; so that vessels of considerable burden may pass below it without interruption. The width of the bridge, or breadth of the roadway, is 32 feet: it is

Section of the Bridge.

Frame of one of the Ribs.

formed of six ribs, placed above five feet distant from one another; each rib consists of 125 blocks of cast iron, five feet in height, and two feet broad at the middle. The lines drawn from this to the centre of the curvature, determine the length of the block above and below; and a circle described with the radius of curvature, gives the convexity of the upper part of the block, and the concavity in the lower, agreeable to the curvature of the whole arch of the bridge.

In each of the three longitudinal parts of the block, there is a square groove one inch deep, into which is fitted a bar of wrought iron of the same dimension with the groove; and by

this means the blocks are joined together to form the ribs. These ribs are connected laterally by a hollow bar of cast iron, about 4 inches diameter, and 5 feet long, with flanches through which iron bolts are made to pass it, and the sides of the ribs fixed with screws or forelocks; two of the blocks are joined by the bars of wrought iron, and connected with a bar of another rib, by the iron hollow bar. All the ribs joined together, and connected in the same manner, to complete the arch of the bridge. To support the beams that form the roadway, circular pieces are formed of cast iron, to abut upon one another at their horizontal diameter, the beams that form the roadway resting upon the circular pieces at the vertical diameter, which gives a firmness to these supports, that no weight coming upon the bridge can injure. The beams or planks are then covered with plates of iron, and such materials as are best adapted to form the road, and prevent water passing through to injure the bridge.

We have only to add, that this bridge was constructed under the direction, and chiefly at the expense, of Rowland Burdon, Esq. then M. P. for the county. It was cast at the foundry of Messrs. Walker, of Rotherham, in Yorkshire, and does honour to the projector and ironmasters. It is nearly double the span of that at Builthwas, and more than double the middle arch of Blackfriar's Bridge.

Our only doubt of the durability of iron bridges is, that the water, being blown in by storms, rests on the flats of the iron, and tends to corrode it, and waste its parts. The union of cast and wrought iron certainly produces a larger quantity of oxide or rust, than if all is cast, or all wrought iron. Perhaps, if between these thin plates of lead were placed, the two pieces might have their joints closed, by abutting upon the lead, and the same precaution being taken with the wrought iron, where inserted into the grooves of the cast metal, the water would be prevented from entering, or settling in the interstice.

*Bangor Ferry Iron Hanging Bridge.* (See Plate, fig. 1.)—The iron hanging bridge, constructed over the Menai Strait, by Mr. Telford, consists of one opening of 560 feet between the points of suspension, and 100 feet in height between the high-water line and the lower side of the roadway; and the roadway being horizontal, this height is uninterrupted for the whole 560 feet, except where the natural rock, which forms the western abutment, now interposes. But in addition to these 560 feet, there are four arches on the western and three on the eastern side of the main opening, each fifty feet span, making in all 850 feet, as in the plate, fig. 2.

In regard to the navigation, it is preferable to any bridge of an arched form, because the latter affords the full height of 100 feet only in the middle; whereas the former affords the same full height for the whole of 500 feet, which is a considerable advantage to vessels passing the Menai Strait, as it allows them to stand closer to either shore while passing under the bridge. In regard to economy, this bridge, on the principle of suspension, has equally the advantage, the estimated expense not being more than £70,000: whereas the cheapest of the arched form, made of cast iron, would have cost nearly double that sum.

The roadway (Plate, fig. 3,) consists of two carriageways, each 12 feet in breadth, with a footpath of 4 feet between them, so that the platform will be about 30 feet in breadth. The whole is to be suspended from four lines of strong iron cables by perpendicular iron rods, placed 5 feet apart, and these rods will support the roadway framing. The suspending power is calculated at 2016 tons, and the weight to be suspended, exclusive of the cables, is 342 tons, leaving a disposable power of 1674 tons. The four sides of the roadways, made of framed ironwork, are firmly bound together for 7 feet in height, and there will be similar work, for 5 feet in depth below the cables. The weight of the whole bridge, between the points of suspension, is 489 tons.

It is calculated that the contraction and expansion of the iron cables may occasion a rise or fall to the extent of four or five inches; but the variations of the temperature of the atmosphere will not derange the bridge.

The two piers are 60 feet by 42 and a half wide, at high-water mark, having a foundation of rock. These piers, connected with the whole of the masonry, form a mass constructed

*London Bridge.*

with blocks of hard limestone, of much greater weight than is necessary for supporting a bridge of this kind. Upon the summit of the two main piers is erected a frame of cast iron, of a pyramidal form, for the purpose of raising the cables from which the bridge is suspended. As the cables are carried from the top of the pyramids, so as to form nearly similar angles on each side, the pressure is almost perpendicular.

Along each line there are four cables, making in the whole sixteen; these cables pass over rollers fixed on the summits of the pyramids, and are fastened at their extremities to an iron frame, lying horizontally over the top of the small arches, and under a mass of masonry.

From these cables the roadway is suspended by vertical iron rods, connected at their lower extremities with wrought-iron bars, both transversely and longitudinally, thus forming a frame on which timber is laid for the roadway. The distance of five feet is kept between the rods, that the suspending power may be equally distributed throughout the whole length of the bridge. The suspending rods pass between the cables, and depend upon each two of them, so that the general strength of the bridge could not materially be affected by taking one way. The cables and the flooring, as well as the suspending rods, are constructed and united in such a manner, that each of the parts may be taken out and replaced separately; so that there can be no difficulty in repairing any part of the bridge, whenever required. A temporary wire-bridge was made from one abutment to the other, to carry over the cables, and arrange the several parts of the bridge, while building.

The weight of each separate cable between the points of suspension is estimated at nine tons and three-quarters, or 117 pounds per yard. The weight of a drove of oxen is calculated at about 300 tons, supposing them to amount to 200 head, all closely huddled together; and the estimated weight necessary to tear the cables asunder is upwards of 2000 tons, which is about four times the weight of the entire bridge. The passing of a mail-coach over the bridge produces no undulation, or sensible perpendicular vibration; nor is any lateral vibration apprehended from the most violent gale of wind, by reason of the proportion that the breadth of the bridge bears as a frame to its extreme length. The bars, as well as the segments, are each joined longitudinally to the whole of the required length and secured by bucklings every five feet, and then enveloped in flannel, well saturated with a composition of rosin and beeswax, to preserve them from the weather, and the whole are encircled with iron wire.—All these details will be clearly understood by reference to the engraving that exhibits the passage upon the bridge.

*The Strand or Waterloo Bridge.* (See Plate, *Bridges*).—This bridge, which is now called "Waterloo Bridge," but which was, till within some few months of its completion, styled "the Strand Bridge," is a noble ornament of the metropolis. The view of the Surrey hills, and the fine expanse of country that it opens from the Strand, is both delightful and surprising; and the effect is not a little increased by the continuity of houses that every where affects the passenger's eye, in passing along the Strand, till he comes to the grand entrance, leading to Waterloo Bridge. For upwards of a century, a bridge at this particular part of the river had been frequently suggested; but all the merit of the scheme, and the influence of the Bedford family, whose property would be so much improved by the adoption of the plan, did not enable it to resist opposition from the city of London, &c. in former periods. It remained for George Dodd, an enterprising and young civil engineer, after three years' unprecedented turmoil, to get an act of parliament for a bridge at this station; and this was not done till subscriptions to the amount of £500,000 had been raised. This was in 1806. Mr. Dodd succeeded in removing the impracticabilities, which had before prevented the scheme of building a bridge across this portion of the river from being carried into effect; and he gave the present plan and dimensions of the bridge.

Some time after the act had been obtained, and the commencement of the building, Mr. Dodd disagreed with the company, and separated from them, and the late Mr. Rennie followed; and he had the honour of finishing this noble bridge, which is different from all the other bridges. All its arches, which are elliptical, are of an equal size; and the road across

the bridge is thus made a level road. The style of its architecture is plain; the effect noble, from its simple grandeur; and the materials are of the most durable kind, namely, of granite. It was built with amazing rapidity, and the ceremony of opening it took place June 18, 1817, the anniversary of the battle of Waterloo. The ceremony was of a splendid character, the Prince Regent and the Duke of Wellington being present on the occasion.

The following are the dimensions of the bridge:—

|                                                                                                                           |          |
|---------------------------------------------------------------------------------------------------------------------------|----------|
| The length of the stone bridge within the abutments,                                                                      | 1242 ft. |
| Length of the road supported on brick arches on the Surrey side of the river,                                             | 1250     |
| Length of the road supported on brick arches on the London side,                                                          | 400      |
| Total length from the Strand, where the building begins, to the spot in Lambeth, where it falls to the level of the road, | 2890     |
| Width of the bridge within the balustrades,                                                                               | 42       |
| Width of the pavement or footway on each side,                                                                            | 7        |
| Width of road for horses and carriages,                                                                                   | 28       |
| Span of each arch,                                                                                                        | 120      |
| Thickness of each pier,                                                                                                   | 20       |
| Clear waterway under the nine arches, which are equal,                                                                    | 1080     |
| Number of brick arches on the Surrey side,                                                                                | 40       |

The whole of the outside courses of the bridge is Cornish granite, except the balustrades, which are of Aberdeen granite; and the stones, like those of the Temple of Solomon, were cut to their respective forms at the quarries, before they were brought to London.

There are 320 piles driven into the bed of the river under each pier. The length of each pile is from 19 to 22 feet, and the diameter about 13 inches. There is one pile to every yard square.

The scientific manner in which the centres were constructed was admirable; and as all the arches are of the same size, the centres were removed from those that were finished, and placed on the piers where the arches were not yet thrown: this was an operation that required great skill and care, and was very ably executed.

When the centres were removed, so solidly and well was the masonry constructed, that in the middle they only sunk about one inch. Those of the Pont de Neuilly, in France, six miles from Paris, which are nearly similar, sunk about 18 inches in the middle, after the centres were taken away. The scientific principle on which the centres were constructed, which did great credit to Mr. Rennie the engineer, was that of the *longitudinal incompressibility of timber*. The strongest and largest beams of wood bend and yield when pressed upon laterally; and by that means the form of a centre, constructed in the usual manner, is different when loaded, from what it is when not loaded; but as no weight that men are acquainted with, when acting gradually, will shorten the length of a beam, it was so contrived that the pressure acted always longitudinally or lengthwise, and not laterally or sidewise; so that those centres remained in form unchangeable, as much as if they had only one solid mass of matter, the two extreme points resting on the firm and well-constructed piers.

In circular arches, such as those of Westminster, or other bridges, the pressure on the centres, before the keystones are put in their place, is not near so good as in elliptical arches, like those of Waterloo.

The four toll-lodges are neat appropriate Doric structures. There is a clever contrivance at each lodge, for the purpose of checking. The kind of iron turnstiles, which admit of only one person passing at a time, touch some machinery which communicates with a clock, locked up in a box in each toll-house, the index of which is thereby moved, so that on looking at it, the number of those who have passed is directly seen.

The bridge was only six years in building. It is exactly on a level with the Strand, where it joins, and is 50 feet above the surface of the water of the river Thames.

The first stone of the bridge was laid on Friday, the 11th of October, 1811, by Mr. Henry Swann; a bottle containing coins of his late Majesty's reign, was deposited in the first

stone, over which a plate with the following inscription was laid:—

"This foundation of the Strand Bridge was laid on the 11th day of October, A. D. 1811, by the Directors for executing the same, Henry Swann, Esq. M.P. chairman, in the 51st year of the reign of King George the Third, and during the regency of his R. H. George Prince of Wales. The money for building which was raised by subscription, under the authority of an Act of Parliament. Engineer, JOHN RENNIE, F.R.S."

*Vauxhall Bridge.* (See Plate, *Bridges*.)—This bridge was originally projected by Ralph Dodd, the father of the engineer above alluded to; but with the actual building of this bridge, Ralph Dodd had little or nothing to do. See *Leigh's Picture of London*.

Some subscriptions were received, and the building of a bridge on the present site of Vauxhall bridge was determined on; but in the co-operation of this, Mr. Dodd was, on account of some disagreements, dispensed with. Mr. Rennie, the Waterloo-bridge engineer, followed. An immense quantity of good stone was brought; laborious efforts were made to build the piers, &c.; but thousands of pounds were expended to no purpose. The completion of the bridge was interrupted till Mr. Walker was engaged; and the result was, the building of the present elegant iron bridge. The whole expense of building was within £150,000; and much more is said to have been previously expended in vain.

The first stone of this bridge was laid in the year 1813, by Prince Charles, the eldest son of the late Duke of Brunswick; and the present beautiful erection was completed in 1816. It consists of nine cast-iron arches, with piers formed by a wooden frame as a foundation, faced with Kentish rag-stone and Roman cement.

*Southwark Bridge.* (See Plate, *Bridges*.)—The plan of this bridge was originally proposed and brought forward by Mr. John Wyat, with the view of forming a communication between Bankside, Southwark, and the bottom of Queen-street, Cheapside. The celebrated Rennie has the merit of the design. It consists of three arches only, of cast iron, from the foundry of Messrs. Joshua Walker and Co. of Rotherham, in Yorkshire, on massy stone piers and abutments.

This is a most stupendous iron bridge; and, so far as respects its centre arch, is of greater span than any other in the world. It was opened in April, 1819. Doubts having existed with the unscientific part of the public, as to the practicability of this Herculean structure, whether it could, in its colossal strides, span the frontiers of old father Thames, the following curious and interesting particulars cannot fail to be acceptable.

This work was begun on the 23d September, 1814, under the direction of Mr. Rennie as engineer, and Mr. Weston, sub-engineer. Messrs. Jolliffe and Banks were the contractors at a lump or specific sum, and, what is rather a novelty in public works of this vast magnitude, it was completed within the contract price. The estimated expense of the bridge amounted to £287,000.

The distance between the abutments is 708 feet. The extent of each abutment enclosed, including the land arch and invert arch, is 71 feet, formed of solid masonry; all the springing stones of which weigh 13 tons each, and are of granite, similar to the other parts of the bridge stone work. There are two piers, 60 feet high each from the bed of the river to the top of the parapet, and 24 feet in breadth between high and low water marks, and 75 feet long between acme and acme of the salient angles. The foundations of the piers are each about

12 feet below the bed or bottom of the river, and rest on a platform of 2½ feet thick of solidly compacted timber; and these platforms each further repose on about 420 piles, most of which are driven 24 feet into the earth, making the depth of the earth, from the shoe of the piles to the parapet top of the piers, 98 feet. There are three arches of iron; the two side ones are 210 feet each in span, and the centre arch is 240 feet in span, with 43 feet clear opening above low-water mark, medium tides. Thus it exceeds the admired bridge of Sunderland by 4 feet in the span, and the long-famed Rialto at Venice, by 167 feet. Many of the iron single or solid castings weigh 10 tons each: and the total weight of iron exceeds 5308 tons.

The centerings of this bridge on which the arches were formed or turned, were of such a novel and peculiar construction, that the navigation of the Thames was comparatively unimpeded during the building of the bridge. The entire centering of one arch, containing 480 loads of timber, was removed into two tides, having been previously and gradually sunk by loosening of the wedges; unlike the Pont Neully, from which the centerings were all struck simultaneously, or rather thrown into the river Seine, and in which the arches settled the surprising depth of 18 inches almost instantly. It was calculated, and allowed, that the centre arch of Southwark bridge would settle at the vertex two inches, yet it has only settled or sunk 1½ inch precisely; thus the wide expanse is within one-eighth of an inch of the figure and form it was originally designed to assume.

The following is a specification of the lengths of the several bridges:

|                                                          | Feet. |
|----------------------------------------------------------|-------|
| Waterloo Bridge, within the abutments, .....             | 1242  |
| Westminster Bridge, from wharf to wharf, .....           | 1223  |
| Blackfriars' Bridge, .....                               | 940   |
| London Bridge, .....                                     | 900   |
| Vauxhall cast-iron Bridge, .....                         | 860   |
| Southwark cast-iron Bridge, between the abutments, ..... | 708   |

*New London Bridge.*—This work was commenced on the 6th March, 1824, under the direction of Mr. John Rennie; second son of the late celebrated engineer (whose stupendous works reflect so much honour on himself and country,) assisted by Mr. James Hollinsworth and Mr. Knight. The bridge is to consist of five beautiful semi-elliptical arches, the centre one of which will be 150 feet span, the adjoining 140 feet, and the land arches 130 feet. They are now constructing of the most durable granite from Aberdeen, Devonshire, and Cornwall, and may be justly considered the boldest of their kind in Europe.

The contractors for this stupendous undertaking are the same who have carried into effect so satisfactorily the other two works of a similar nature, viz. Waterloo and Southwark bridges. (Messrs. Jolliffe and Banks.) And from the sound and scientific manner in which the work under remark is proceeding, there is every reason to believe that they will speedily complete it to general satisfaction.—Their contract for the new bridge, and some alterations in widening the water-way of the old one, is £506,000, and they are bound down in heavy sureties to complete it in March, 1830.

|                                      |          |
|--------------------------------------|----------|
| Original contract, .....             | £426,000 |
| Additional width, .....              | 42,000   |
| Fourth, sets of centres, .....       | 8,000    |
| Alteration, of the old bridge, ..... | 30,000   |

Total, 506,000

It is understood that the removal of the old structure will be a separate contract.

**BRIGGS, HENRY**, is well known as the improver of Napier's logarithms. This great man was born at Warley Wood, Halifax, Yorkshire, in 1556, and died at Oxford in 1630. He preferred retirement to the splendours of life, and humble probity to the accumulation of vast riches, which his abilities might have procured.

**BROKEN-BACKED**, the state of a ship, so loosened in her frame, either by age, weakness, or some great strain, as to droop at each end. This circumstance is more common among the French than the English or Dutch ships, owing partly to their great length, and to the sharpness of their floor, whose breadth is not sufficiently carried from the middle towards each end, and partly from being frequently obliged to have a great weight on both ends, when they are empty in the middle, at the time of discharging one cargo and taking in another.

**BULK-HEADS**, partitions built up in several parts of a ship, to form and separate the various apartments; some of which are particularly strong. Others are light, and removable at pleasure, to clear the ship for action. The bulk-head afore, is the partition between the fore-castle and the gratings in the head, and in which are the chase ports.

**BULL'S EYE**, a piece of wood in the form of a ring, which answers the purpose of an iron thimble: it is seldom used by the English seamen, and then only for the main and fore bow-line bridles.

**BUMBOAT**, a small boat, employed to carry vegetables, &c. for sale, to ships lying at a distance from the shore.

**BUMKIN**, or **BOOMKIN**, a short boom, or beam of timber, projecting from each bow of a ship, to extend the clue or lower corner of the foresail to windward; for which purpose there is a large block fixed on its outer end, through which the tack is passed, which being drawn tight down, the tack is said to be aboard.

**BUNT-LINES**, ropes fastened to cringles on the bottoms of the square sails, to draw them up to their yards: they are inserted through certain blocks above, or on the upper part of the yard, whence passing downwards on the forepart of the sail, they are fastened below to the lower edge, in several places of the bolt rope.

**BUNT-LINE CLOTH**, the lining sewed up the sail in the direction of the bunt-line, to prevent that rope from chafing the sail.

**BUOY**, a sort of close cask, or block of wood, fastened by a rope to the anchor, to point out its situation. Buoys are of various kinds, as, *Can Buoys*, which are in the form of a cone. Of this kind are the buoys which are floated over sands, &c. as marks for ships to avoid them: they are made very large, that they may be seen at a distance; where there are several near each other, they are distinguished by the colour, as black, red, and white. *Nun Buoys*, are large in the middle, and taper nearly to a point at each end. *Wooden Buoys*, are solid pieces of light timber, having one or two holes through the ends, in which is fixed a ring of rope called the strop.

*Cable Buoys* are common casks, employed to buoy up the cables in rocky anchorage, to prevent their rubbing against the rocks. In the harbour of Alexandria in Egypt, every ship is moored with at least three cables, and has three or four of these buoys on each cable for this purpose.

*Life Buoy* is generally of the Can kind, though sometimes it is made of cork. It is furnished with a small flag on the top, and is used to throw overboard for a person who has fallen into the sea to lay hold of; while the flag serves to direct a boat to the spot, and thereby frequently saves the life of a fellow creature.

*Buoy Rope*, the rope which fastens the buoy to the anchor, and should be always of sufficient strength to draw up the anchor; it should also be little more in length than equal to the depth of the water where the anchor lies.

**BURNING**, the action of fire on bodies, whereby the minute parts of them are separated, and thrown into violent motion, some of them assuming the nature of fire themselves, fly off *in orbem*, while the rest are dissipated in form of vapour, or reduced to ashes.

**BURNING Glass**, a convex lens which transmits the rays of light, but in their passage refract or incline them towards a common point in the axis called the focus; and by thus combining together in a single point the power of all the rays

transmitted through the glass, a very great degree of heat is accumulated in that point, which will fuse bodies that are infusible in the greatest culinary heat that can be produced.

**BURNING Mirrors**, or *Specula*, are concave reflecting surfaces, commonly of metal, which reflect the rays of light falling upon them, but at the same time incline them towards a determined point or focus, where their accumulated effect operates in the most powerful manner, burning and dissipating the hardest and most infusible bodies.

Those burning glasses which consist of refracting convex lenses, though not entirely unknown, were very imperfectly understood by the ancients; but the latter kind, the burning mirrors, they seem to have had in greater perfection than the moderns, at least if we may credit the relations of several eminent historians, who assert that Archimedes, by means of such mirrors, burned and destroyed the Roman fleet, which, under Marcellus, was employed at the siege of Syracuse; and that Proclus in the same way destroyed the navy of Vitellius, at the siege of Byzantium.

There are also passages in some of the ancients, which seem to indicate that they also possessed a knowledge of the burning powers of refractors, although their magnifying powers appear to have been wholly unknown to them. Among the moderns, one of the earliest who devised a burning mirror, was the celebrated Lord Napier, the inventor of logarithms.

Of the moderns, the most remarkable burning glasses are those of Magine, of 20 inches diameter; of Sepatala, of Milan, near 42 inches diameter, and which burnt at the distance of 15 feet; of Settala, of Vilette, of Tschirnhausen, of Buffon, of Trudaine, and of Parker.

That of M. de Vilette was 3 feet 11 inches in diameter, and its focal distance was 3 feet 2 inches. Its substance is a composition of tin, copper, and tin glass. Some of its effects, as found by Dr. Harris and Dr. Desaguliers, are, that a silver sixpence melted in  $7\frac{1}{2}$ "; a king George's halfpenny melted in 16", and ran in 34"; tin melted in 3"; and a diamond, weighing 4 grains, lost  $\frac{1}{4}$ ths of its weight.

That of Buffon is, (see Archimedes' mirror, in the following figure), a polyhedron, 6 feet broad, and as many high, consisting of 168 small mirrors, or flat pieces of looking-glass, each 6 inches square, by means of which, with the faint rays of the sun in the month of March, he set on fire boards of beech wood at 150 feet distance. Besides, his machine has the conveniency of burning downwards or horizontally, as one pleases, each speculum being moveable, so as, by means of three screws, to

be set to a proper inclination for directing the rays towards any given point; and it turns either in its greater focus, or in any nearer interval, which our common burning glasses cannot do, their focus being fixed and determined. Buffon, at another time, burnt wood at the distance of 200 feet; and melted tin and lead at the distance of more than 120, and silver at 50 feet.

The following figure represents another contrivance of Buffon, for diminishing the thickness of very large refracting lenses, in which the burner consists of concentric pieces of glass, each resting upon the other, as represented in the figure, by dividing the convex arch of the lens into three equal parts. Thus, suppose the diameter to be 26 inches, and the thickness

in the middle 3 inches; by  $\div$  the lens into three concentric O's, and laying the one over the other, the thickness of the

middle piece need only be one inch; at the same time that the lens will have the same convexity, and almost the same focal distance, as in the other case, while the effects of it must be much greater on account of the greater thickness of the glass.

Mr. Parker, of Fleet-street, London, was induced, at an expense of upwards of £700, to contrive, and at length to complete, a large transparent lens, that would serve the purpose of fusing and vitrifying such substances as resist the fires of ordinary furnaces, and more especially of applying heat in vacuo, and in other circumstances in which it cannot be applied by any other mean, as in the annexed figure. After directing his attention for several years to this object, and performing a great variety of experiments in the prosecution of it, he at last succeeded in the construction of a lens of flint glass, 3 feet in diameter, which, when fixed in its frame, exposes a surface of 32 inches in the clear; the distance of the focus is 6 feet 9 inches, and its diameter 1 inch. The rays from this large lens are received and transmitted through a smaller one of 13 inches diameter, its focal length 29 inches, and diameter of its focus  $\frac{3}{8}$  inch; so that this second lens increases the power of the former, as  $8^2$  to  $3^2$ , or rather more than 7 to 1.

In the elevation, (as in the following figure,) A is the lens of

the diameter mentioned; B is a second lens, 16 inches diameter; C a truncated cone, composed of 21 ribs of wood, in which both lenses are fixed; D is a rack passing through the pillar L; E its handle; F a bar of wood, fixed between the two lower ribs of the cone at G, in which the apparatus H, with the iron plate I, turning on the ball and socket K, to hold thereon the matter under experiment; LL a frame moving on the castors M M. Below the table N are three friction wheels, that move the machine horizontally. O a strong iron bar, in which the lens and the cone hang.

The following figure represents the section. *a* is the great lens marked A in the elevation; *b* the frame containing the great lens; *t* the small lens marked B; *d* the frame that contains the small lens; *e* the truncated cone C; *f* the bar on

which the apparatus F turns; *g* the iron plate marked I; *h* the cone of rays formed by the great lens *a* falling on the lens *t*; *i* the cone of rays formed by the refraction of the lens *t*. In the front view in Mr. Parker's lens, A is the great lens in its circular frame; *m* the iron bow in which it hangs; *l* the support.

From a variety of experiments made with this lens, the following are selected to serve as a specimen of its powers:—

| Substances fused, with their Weight and Time of Fusion. | Weight in Grains. | Time in Seconds. |
|---------------------------------------------------------|-------------------|------------------|
| Gold,....pure.....                                      | 20                | 4                |
| Silver,.. ditto.....                                    | 20                | 3                |
| Copper, ditto.....                                      | 33                | 20               |
| Platina, ditto.....                                     | 10                | 3                |
| Nickel,.....                                            | 16                | 3                |
| Bar iron, a cube.....                                   | 10                | 12               |
| Cast iron, ditto.....                                   | 10                | 3                |
| Steel,.... ditto.....                                   | 10                | 12               |
| Scoria of wrought iron.....                             | 12                | 2                |
| A topaz, or chrysolite.....                             | 3                 | 45               |
| An oriental emerald.....                                | 2                 | 42               |
| Crystal pebble.....                                     | 7                 | 6                |
| Topaz,.....                                             | 10                | 30               |
| Flint oriental.....                                     | 10                | 30               |
| Rough cornelian.....                                    | 10                | 75               |
| Jasper,.....                                            | 10                | 25               |
| Onyx.....                                               | 10                | 20               |
| Garnet.....                                             | 10                | 17               |
| White rhomboidal spar.....                              | 10                | 60               |

Mr. Parker farther informs us, that a diamond weighing 10 grains, exposed to this lens for 30 minutes, was reduced to 6 grains; but gold remained in its metallic state, without apparent diminution, notwithstanding an exposure at intervals of many hours. With regard to experiments on iron, it is remarkable that the lower part, *viz.* the part in contact with the charcoal, was first melted, when that part which was exposed to the focus remained unfused. For farther particulars on this subject see Rees's Cyclopaedia, article Burning Glass; see also an essay on "Mirrors Ardents," by M. Peyrard, subjoined to the French translation of the works of Archimedes.

BURTHEN, or BURDEN, the weight or measure of any species of merchandise that a ship will carry when fit for sea; the general rule for finding which is, to multiply the length of the keel, the inner midship breadth, and the depth from the main deck to the plank joining the keelson, together; which product divided by 94 gives the tonnage, or burden, required in tons.

BUSHEL, a measure for dry goods, which by an act of parliament, passed in 1697, is to contain 2150.42 cubic inches, *viz.* "Every round bushel, with a plain and even bottom, is to

be made 18½ inches wide throughout, and 8 inches deep, which is accounted a legal Winchester bushel, according to the standard in his majesty's exchequer." See WEIGHTS and MEASURES.

**BUTTER, CHEESE, &c.**—Butter is an artificial preparation of cow's milk. The milk, either in its natural state or in that of cream, is whirled round or agitated in a churn, till all its unctuous particles are separated from the whey, and a soft consistent mass is formed.\* Greek authors frequently speak of milk and cheese, but do not mention butter; and the Romans, for six centuries, used it as a medicine. In modern times, the art of making, improving, and preserving butter, has kept pace with the unwholesome custom of eating this animal oil from an early period of infancy. Butter forms a considerable article of trade. 50,000 tons of butter are annually consumed in London; of which the counties of Cambridge and Suffolk are said to furnish 50,000 firkins, each containing 56 lbs. None, however, is equal to that produced in Essex, and known by the name of Epping butter.

Butter, like all inflammable substances, is constantly undergoing oxygenation, as the chemists call it, and by this process becomes rancid, or is changed into a new substance no longer suitable for the purposes of nourishment. The tendency to rancidity, or oxygenation, is much hastened by its greater or less admixture with the other parts of the milk, from which it is not totally freed; for if the parts are very completely separated, the progress of oxygenation is much retarded.

The only means of preserving butter is by means of sea-salt; and with this addition it can be kept long in a fit condition for aliment. The cream, or oily part of the milk, from which butter is made, acquires, by being kept for some time, new properties, and these new properties facilitate its conversion into butter. Thus sour cream does not take one-fourth part of the labour necessary in churning, as fresh cream, in order to give out its product: but this acid which prevails in the cream before churning, disappears also after the process is finished; and this circumstance is no way influenced either by the access or exclusion of the atmospheric air. Fresh butter, as first made, is almost without any smell, of a mild and agreeable taste, easily soluble in water, and remaining uniform even in a boiling heat. As its acid becomes extricated, it acquires an acrimony or rancidity, and is then rendered unwholesome.—This acid is peculiar, and has not yet been properly examined.

The proper quality of butter is marked by its oily or fat shining surface, and its yellow colour, with an agreeable flavour and sweetish taste. The colour varies according to the feeding of the animal, and to supply its defect, adventitious means are often resorted to by colouring it with vegetables. The highest degree of natural colour is generally found in that from the milk of Guernsey cows. From the strong tendency of butter to oxygenation, great quantities of this article come to be sold in a rancid state; and this cannot fail to be attended with the most deleterious consequences, and to lay the foundation of

disease. As the wholesomeness of this article depends on its freedom from rancidity, whatever operation it is subjected to, that produces this state of it, introduces the foundation of disease, whether it arise from keeping, or the processes of cookery in frying and burning. It becomes in this state heavy and indigestible on the stomach, occasioning acrid and acid belchings.

But besides selling it in a rancid state, other deceptions may be adduced in respect to butter, by those who deal in it. By beating, it possesses the quality of absorbing an immense quantity of water. Such advantage is taken of this circumstance, that what with the additional weight of salt also introduced into it, the public do not receive more than two-thirds of the actual product when they buy it. The fraud begins from the very dairy, and is increased when it gets into the hands of the cheesemonger. The poor man is deprived of so much of the nourishment which he ought to have, and, by an excess of extraneous matter introduced into his body, through the use of this sophisticated article, sees himself and his progenitors often suffering under scrofula and other maladies, drawing their origin from, or aggravated by, this impure source.

Cheese, made from curdled milk, freed from the serum or whey, and afterwards dried for use, differs in quality, as it is made from new milk, or from skimmed milk,—from the curd which separates spontaneously upon standing, or that which is more speedily produced with runnet. There is also cheese from cream, which is fat and butyraceous, and does not keep long. Of all the cheese made in England, none is so esteemed as the Stilton. These cheeses must be kept two years before they are properly mellowed for use in families. The making of what is called Stilton cheese is not confined to the Stilton farmers. Others in Huntingdonshire, and even in Rutland and Northamptonshire, make a similar sort, which is sold under the name of Stilton. The double Gloucester is much esteemed. The goodness of Cheddar cheese is said to be owing to the richness of the land: the same is the case with the Somersetshire, and that of the adjoining counties. Cheshire cheese is generally admired. A cheese is sometimes above a hundred pounds weight. To give a high colour to cheese, it is usual to put with the milk, before it is turned, a little annatto. No cheese will look yellow without it, and though it is perfectly innocent, it does not add to the goodness of the cheese.

**BUTTERFLY, To take the Impression of a.** Having caught a butterfly, kill it without spoiling its wings, contrive to spread these out as regularly as possible in a flying position; then, with a small brush or pencil, take a piece of white paper; wash part of it with gum water, afterwards lay your butterfly on the paper, cut off the body close to the wings, throw it away, lay the paper on a smooth board, with the fly upwards; lay another paper over that, put the whole preparation into a screw press, and screw it hard down, or otherwise press it, for half an hour. Afterwards take off the wings of the butterfly, and you will find their perfect impression, with all their various colours marked distinctly, on the paper. When this is done, draw between the wings of your impression the body of the butterfly, and colour it after the insect itself.

\* There are also vegetable butters made from palm oil, and the oil of the cocoa nut. The celebrated Park found, in Africa, a tree called by the natives shea, from the fruit of which a tolerably pure butter was procured.

## C.

### C A B

**CABIN**, a room or apartment in a ship, where any of the officers usually reside. In a large ship there are several cabins, the principal of which, distinguished by the name of the great cabin, is designed for the captain or commander. In ships of the line, this chamber is furnished with an open gallery in the ship's stern, as also a little gallery on each quarter.

**CABINET**, a secret or inner apartment; also a piece of joiner's work resembling a press or chest; likewise a council, or select meeting, is called a cabinet.

### C A B

**CABLE**, a thick, stout rope, made of hemp, &c. to keep a ship at anchor. Every cable is of three strands, every strand of three ropes, every rope of three twists; and the twists are spun of more or less threads, as the cable is to be thick or small. Thus, a cable of one inch diameter, or three inches circumference, consists of forty-eight ordinary threads, and weighs 192 pounds. To estimate the strength of a hempen cable, divide by 5, the square of its girth in inches, and the quotient will express in tons the utmost strain it can bear.

Hence, a rope of 1 inch diameter is capable of bearing a strain of 1·8 ton.

| Circum.  | Thread.    | Weight.—lbs. | Strain.—Tons. |
|----------|------------|--------------|---------------|
| 4 .....  | 77 .....   | 308 .....    | 3·2           |
| 6 .....  | 174 .....  | 696 .....    | 7·2           |
| 8 .....  | 311 .....  | 1244 .....   | 12·8          |
| 10 ..... | 485 .....  | 1940 .....   | 20·0          |
| 14 ..... | 952 .....  | 3808 .....   | 39·2          |
| 18 ..... | 1574 ..... | 6296 .....   | 64·8          |
| 20 ..... | 1943 ..... | 7772 .....   | 80·0          |

This estimate applies to new ropes, formed of the best materials, not much twisted, and having the strands laid even. If yarns, of 180 yards long, be worked up into ropes 120 yards only, it will lose one-fourth of the strength, the exterior fibres alone resisting the greatest strain.

The long cable is not so apt to break as the short one, because it will bear a great deal more stretching before it comes to the greatest strain; it therefore resembles a sort of spring, which may be very easily extended, and afterwards recovers its first state, as soon as the force which extended it is removed. Besides all this, a ship will ride much smoother with a long cable, and be less apt to pitch or plunge deep in the water with the fore part. On the contrary, the short cable, being too nearly vertical to the anchor, cannot bear such a strain, because it is charged with a greater effort; and, as it will not bear stretching, may break the first violent tug. The ship also rides with much greater difficulty, labours extremely, and often plunges all her fore part under water. Every ship should be furnished with sufficiency of cables, or what is called ground tackle; for owing to a deficiency of this necessary article, many excellent vessels have been lost, and it is an inconsiderate policy indeed, in merchants, to expose their ships to such evident dangers for the want of them.

**CAGE**, an enclosure of wire, or wicker, for the confinement of birds or wild beasts. **CAGE** means also, in carpentry, some outer work, or timber enclosing other timber, as, the cage of a windmill; the cage of a staircase, the wooden walls or sides that enclose it.

**CALAMINE**, a mineral composed of zinc, iron, and sometimes other substances; its colour is sometimes whitish or gray; at other times brown or blackish, red or deep yellow.

**CALAMUS**, the rotang, or true Indian cane, abundant in Sumatra, is one of those plants from which the drug, called dragon's blood, is obtained.

**CALASH**, a small light chariot, or garden chair, of which a new sort going on two wheels has been invented; not hung on traces and springs, yet easier than the common coaches, and possessing the singular advantage of recovering its proper position, should it, by any irregularity of the road, or other accident, be overturned.

**CALCAR**, a small oven, or reverberatory furnace, in which the first calcination of sand and potashes is made, for turning them into *frit*, from which glass is ultimately made. This furnace, 10 feet long, 7 wide, 2 deep, is heated by flame reverberating from the roof upon the frit, over the surface of which the smoke rolls quite black, escaping by the mouth of the calcar. The coals burn on grates of iron, to allow the ashes to precipitate.

**CALCAREOUS EARTH**, the same as lime, and of which there are various combinations, as marble, limestone, marle, gypsum. Vast quantities of marine shells, and the bones of animals, are found imbedded in it.

**CALCINATION**. See **CHEMISTRY**.

**CALCULATION**, the act of computing, as in Arithmetic, Astronomy, Geometry, &c.

**CALCULUS**, among Mathematicians, denotes a certain way of performing mathematical operations.

**CALCULUS**, in Medicine, the disease of the stone in the bladder or kidneys; the term is Latin, and signifies a *little pebble*. Hard waters, that contain limy earth, contribute to the formation of human calculi.

**CALENDAR**, in Chronology, a distribution of time, accommodated to the purposes of civil life, exhibiting the order of days, weeks, months, festivals, &c. that happen and succeed in the course of one year. The calendar of Romulus,

or the ancient Romish year, consisted of ten months, namely, *Martius* of thirty-one days, *Aprilis* of thirty, *Maius* of thirty-one, *Junius* thirty, *Quintilis*, of thirty-one, *Sextilis* of thirty, *September* of thirty, *October* of thirty-one, *November* of thirty, *December* of thirty; in all, three hundred and four days.

The Roman year of Numa consisted of twelve months. *Januarius* had twenty-nine days, *Februarius* twenty-eight, *Martius* thirty-one, *Aprilis* twenty-nine, *Maius* thirty-one, *Junius* twenty-nine, *Quintilis* thirty-one, *Sextilis* twenty-nine, *September* thirty-one, *October* twenty-nine, *November* twenty-nine; *December* twenty-nine; in all, three hundred and fifty-five. The months called *Quintilis* and *Sextilis*, from their order in Romulus's year, were changed into *Julius* and *Augustus*, in honour of *Julius Cæsar* and his successor *Augustus*.

The *Julian* year consists of twelve months, viz. *January* of thirty-one days, *February* of twenty-eight, *March* of thirty-one, *April* of thirty, *May* of thirty-one, *June* of thirty, *July* of thirty-one, *August* of thirty-one, *September* of thirty, *October* of thirty-one, *November* of thirty, *December* of thirty-one; in all three hundred and sixty-five. Every fourth year, in the *Julian* account, has three hundred and sixty-six days, *February* then having twenty-nine, as we have before observed. The *Gregorian* year has the same number of months and days as the *Julian*, the only difference being that each month in the former begins eleven days sooner than the latter.

The *Jewish* year consists of twelve months. *Nisan* or *Abib* has thirty days, *Jiar* or *Zius* twenty-nine; *Siban* or *Sivan* thirty, *Thamus* or *Tamus* twenty-nine, *Ab* thirty, *Elul* twenty-nine, *Tisri* or *Ethanim* thirty, *Marchescan* or *Bul* twenty-nine, *Cisleu* thirty, *Tebeth* twenty-nine, *Shebat* or *Schebeth* twenty-nine, *Adar* twenty-nine; in all three hundred and fifty-four. This is made to agree with the *solar year*, by adding eleven, and sometimes twelve days.

As the form of the year is various among different nations, so likewise is its beginning. The Jews, like other nations of the East, had a civil year, which commenced with the moon in September; and an ecclesiastical year, which began from the new moon in March. The Persians begin their year in the month answering to June. The Chinese and most of the Indian nations begin it with the first moon in March; and the Greeks with the new moon that happens next after the summer solstice.

In England, the civil or legal year formerly commenced on the 25th of March, and the historical year on the first day of January. But since the alteration of the style, in 1752, the civil year, in this country, as we observed before, has likewise begun on the first of January.

**CALENDS**, or **KALENDS**, in the Roman Chronology, the first day of every month. It was one of the offices of the pontifices to watch the appearance of the new moon, and give notice thereof to the high priests; upon which a sacrifice being offered, the pontiff summoned the people together in the Capitol, and there with a loud voice proclaimed the number of calends, or the day whereon the nones would be; which he did by repeating a formula as often as there were days or calends. And hence also our term calendar.

The *Nones* were the 5th day of January, February, April, June, August, September, November, and December, and the 7th of March, May, July, and October. And the *Ides* happened 9 days after the nones; that is, on the 13th day of February, April, June, August, September, November, and December; and on the 15th of March, May, July, and October.

**CALIBER**, or **CALIPER**, properly denotes the diameter of any round body: thus we say the caliber of the bore of a gun, the caliber of a shot, &c.

**CALIBER** or **CALIPER** *Compasses*, or simply *Calipers*, a sort of compass made with bowed or arched legs, for the purpose of taking the diameter of any round body.

**CALICO**, a cloth made from cotton wool, resembling linens; the name is from *Calicut*, a city in India, from whence the Spaniards or Portuguese first brought calicoes.

**CALICO-PRINTING**, or the art of applying coloured patterns on a white or coloured ground of linen or cotton, has been practised in India for more than two thousand years, but has not been cultivated in Europe more than a century. This art depends on the action of certain bodies, which, by chemical agency, permanently unite the colouring matter of dyeing

materials to particular parts of the cloth. The substances which bind the colouring matters to the faces of the cloth, are denominated mordants. The mordant is applied to the cloth by wooden blocks, in which the patterns are carved in relief. This effect is also produced by means of a small brush, by sheet copper fixed in a block, like filligree work, or by the copper-plate. When the mordant has been applied, the cloth is made completely dry; and washed in water, till the thickening matter, and those parts of the mordants uncombined with the cloth, are removed. After this, the cloth is rinsed in clean water. It is then dipped in the dye liquor, by which the whole is dyed. The parts which have been impregnated in the mordant receive a brighter colour than those which have not. The colour of the former is permanent, but that of the latter is discharged by repeated washing.

Calico-printing, we have said, consists in impregnating those parts of the cloth which are to receive a colour, with a mordant, and then dyeing it as usual with some dye stuff or other. The dye stuff attaches itself firmly to that part of the cloth only which has received the mordant. The whole surface of the cotton is indeed more or less tinged, but by washing and bleaching, all the unmordanted parts resume their original colour, while those which have received the mordant retain it. Let us suppose, that a piece of white cotton cloth is to receive red stripes; all the parts where the stripes are to appear are pencilled over with a solution of acetite of alumine; after this, the cloth is dyed in the usual manner with madder. When taken out of the dyeing vessel it is all of a red colour, but by washing and bleaching, the madder leaves every part of the cloth white, except the stripes impregnated with the acetite of alumine, which remain red. Thus it is obvious, that it is not the cloth but the mordant which has retained the dye. In the same manner may yellow stripes, or any other wished-for figure, be given to cloth, by substituting quercitron bark, weld, &c. for madder.

When different colours are to be given to different parts of the cloth at the same time, it is done by impregnating it with various mordants. Thus, if stripes be drawn upon a cotton cloth with acetite of alumine, and other stripes with acetite of iron, and the cloth be afterwards dyed in the usual way with madder, and then washed and bleached, it will be striped red and brown. The same mordants with quercitron bark, give yellow and olive, or drab.

The mordants employed in calico-printing are, acetite of alumine, and acetite of iron. These mordants are applied to the cloth, either with a pencil, or by means of blocks. As the mordants are applied on to particular parts of the cloth, care must be taken that none of them spread to the part of the cloth which is to be left white, and that they do not interfere with one another, when more than one are applied. If these precautions be not attended to, all the elegance and beauty of the print will be destroyed.

It is necessary, therefore, that the mordants should be of such a consistence, as not to spread beyond those parts of the cloth on which they are applied. This is done by thickening them with flour or starch, when they are to be applied by the block; and with gum arabic, when they are to be put on by a pencil. The thickening should never be greater than is sufficient to prevent the spreading of the mordants; when carried too far, the cotton is apt not to be sufficiently saturated with the mordants; and of course, the dye takes but imperfectly. In order that the parts of the cloth impregnated with mordants may be distinguished by their colour, it is usual to tinge the mordants with some colouring matter or other. The printers commonly use the decoction of Brazil wood for this purpose; but the Brazil wood colouring matter impedes the subsequent process of dyeing. The mordant should therefore be coloured with some of the dye stuff afterwards to be applied, but not more than is sufficient to make the mordant distinguishable when applied to the cloth. The reason is obvious. If too much dye be mixed with the mordant, a great proportion of the mordant will be combined with colouring matter, which must weaken its affinity for the cloth, and of course prevent it from combining with it in sufficient quantity to ensure a permanent dye. Sometimes these two mordants are mixed together in different proportions; and sometimes one or both is mixed with

an infusion of sumach, or of nut galls. By these contrivances, a great variety of colours are produced by the same dye stuff. After the mordants have been applied, the cloth is dried by artificial heat, which contributes towards the separation of the acetous acid from its base, and towards its evaporation, by which the mordant combines in a greater proportion, and more intimately with the cloth.

When the cloth is sufficiently dried, it is to be washed with warm water and cow-dung, till all the flour, or gum, employed to thicken the mordants, and all those parts of the mordants which are uncombined with the cloth, be removed. After this, the cloth is thoroughly rinsed in clean water. Almost the only dye stuffs employed by calico-printers, are indigo, madder, and quercitron bark, or weld. This last substance, however, is but little used by the printers of this country, except for delicate greenish yellows. The quercitron bark has almost superseded it, because it gives colours usually good, and is much cheaper and more convenient, not requiring so great a heat to fix it. Indigo not requiring any mordant, is commonly applied at once, either with a block or a pencil. It is prepared by boiling together indigo, potash made caustic by quicklime, and orpiment; the solution is afterwards thickened with gum. It must be carefully secluded from the air, otherwise the indigo would soon be regenerated, which would render the solution useless. Coarse brown sugar, as a substitute for orpiments, is equally efficacious in decomposing the indigo, and rendering it soluble; while it likewise serves all the purposes of gum.

When the cloth, after being impregnated with the mordant, is sufficiently cleansed, it is dyed in the usual manner, and the whole is more or less tinged with the dye stuff. It is well washed, and then spread out for some days on the grass, and bleached with the wrong side uppermost. This carries the colour off completely from all parts of the cotton which have not imbibed the mordant, and leaves them of their original whiteness, while the mordanted spots retain the dye as strongly as ever.

We will now give some examples of the manner in which printers give particular colours to calicoes. Some calicoes are only printed of one colour, others have two, others three or more, even to the number of eight, ten, or twelve. The smaller the number of colours, the fewer in general are the processes.

One of the most common colours on cotton prints is a kind of nankeen yellow, of various shades, down to a deep yellowish brown, or drab. It is usually in stripes or spots. To produce it, the printers besmear a block, cut out into the figure of the print, with acetite of iron, thickened with gum or flour; and then apply it to the cotton, which, after being dried and cleaned in the usual manner, is plunged into a potash ley. The quantity of acetite of iron is always proportioned to the depth of the shade. For yellow, the block is besmeared with acetite of alumine. The cloth, after receiving the mordant, is dyed with quercitron bark, and then bleached. Red is communicated by the same process, only madder is substituted for the bark. The fine light blues which appear so often on printed cottons, are produced by applying to the cloth a block besmeared with a composition, consisting partly of wax, which covers all those parts of the cloth which are to remain white. The cloth is then dyed in a cold indigo vat; and after it is dry, the wax composition is removed by hot water.

Lilac brown, and blackish brown, are given by means of acetite of iron; the quantity of which is always proportioned to the depth of the shade. For very deep colours, a little sumach is added. The cotton is afterwards dyed in the usual manner with madder, and then bleached.

Dove colour and drab, by acetite of iron and quercitron bark. When different colours are to appear in the same print, a greater number of operations are necessary. Two or more blocks are employed, upon each of which, that part of the print only is cut, which is to be of some particular colour. These are besmeared with different mordants, and applied to the cloth, which is afterwards dyed as usual. Let us suppose, for instance, that these blocks are applied to cotton, one with acetite of alumine, another with acetite of iron, a third with a mixture of those two mordants, and that the cotton is then dyed with quercitron bark, and bleached. The parts impregnated with mordants would have the following colours:—Ac-

tite of alumine, yellow; acetite of iron, olive, drab, dove; the mixture, olive green, olive.

If the part of the yellow be covered over with the indigo liquor, applied with a pencil, it will be converted into green. If the same liquid, blue may be given to such parts of the print as require it. If the cotton be dyed with madder, instead of quercitron bark, the print will exhibit the following colours:—Acetite of alumine, red; acetite of iron, brown, black; the mixture, purple.

When a greater number of colours are to appear; for instance, when those communicated by bark, and those by madder, are wanted at the same time, mordants for part of the pattern are to be applied; the cotton is then to be dyed in the madder bath, and bleached; then the rest of the mordants, to fill up the pattern, are added, and the cloth is again dyed with quercitron bark, and bleached. The second dyeing does not much affect the madder colours; because the mordants, which render them permanent, are already saturated. The yellow tinge is easily removed by the subsequent bleaching. Sometimes a new mordant is also applied to some of the madder colours, in consequence of which, they receive a new permanent colour from the bark. After the last bleaching, new colours may be added by means of the indigo liquor. The following table will give an idea of the colours which may be given to cotton by these complicated processes.—1. *Madder Dye*. Acetite of alumine, red; acetite of iron, brown, black; acetite diluted, lilac; both mixed, purple.—2. *Bark Dye*. Acetite of alumine, yellow; acetite of iron, dove, drab; lilac and acetite of alumine, olive; red and acetite of alumine, orange.—3. *Indigo Dye*. Indigo, blue; indigo and yellow, green.

Thus no less than twelve colours may be made to appear together in the same print, by these different processes. These instances will serve to give the reader an idea of the nature of calico-printing, and at the same time afford an excellent illustration of the importance of mordants in dyeing.

Were it possible to procure colours sufficiently permanent, by applying them at once to the cloth by the block or the pencil, as is the case with the mordants, the art of calico-printing would be brought to the greatest simplicity; but at present this can only be done in one case, that of indigo; every other colour requires dyeing. Compositions, indeed, may be made, by previously combining the dye stuff and the mordants. Thus yellow may be applied at once, by employing a mixture of the infusion of quercitron bark and acetite of alumine, red, by mixing the same mordant with the decoction of alumine, and so on. The colours applied in this way, are, unfortunately, far inferior in permanency to those produced when the mordant is previously combined with the cloth, and the dye stuff afterwards applied separately. In this way are applied almost all the fugitive colours of calicoes, which washing, or even exposure to the air, destroys.

**CALIPPIC Period**, in Chronology, a period of 76 years, continually recurring, after which it was supposed by Calippus, that the lunations, &c. of the moon would return again in the same order; which, however, is not exact, as it brings them too late by a day in 225 years.

**CALOMEL**, dulcified sublimate of mercury, is a combination of mercury with muriatic acid; called also *sub-muriate of mercury*.

**CALORIC**, in Chemistry, a modern term introduced into philosophy, to denote that substance, by the influence of which are produced all the phenomena of heat, and which was formerly distinguished by the term *igneous fluid, matter of heat*, and other analogous demonstrations.

Heat, considered as a sensation, or, in other words, sensible heat, is only the effect produced upon our organs by the motion of caloric, disengaged from surrounding bodies. To illustrate this, let us observe, that in general we receive the impression only in consequence of motion, and it might be established as an axiom, that without motion there is no sensation. This general principle applies very accurately to the sensations of heat and cold. When we touch a cold body, the caloric, which always exerts itself to attain an equilibrium in all bodies, passes from our hand into the body we touch, and give us the feeling or sensation of cold. The contrary happens when we touch a warm body; the caloric then, in passing from the

body into our hand, produces the sensation of heat. If the hand and the body it touches be of the same temperature, or very nearly so, we receive no impression of either heat or cold, because there is no motion or passage of caloric. When the thermometer rises, it shews that the free caloric is entering into the surrounding bodies. The thermometer, which is one of these, receives it in proportion to its mass, and to the capacity which it possesses for containing caloric. Free caloric is that which is not combined in any manner with any body. But as we live in a system, to the matter of which caloric has a very strong affinity, we are never able to obtain it in a state of absolute freedom.

**Combined CALORIC** is that which is fixed in bodies by affinity, or elective attraction, so as to form part of the substance of the body.

**Specific CALORIC**. By the expression of specific caloric of bodies, we understand the respective quantities of caloric requisite for raising a number of bodies, of the same weight, to an equal degree of temperature. This proportional quantity of caloric depends upon the distance between the constituent particles of bodies and their greater or less degree of cohesion; and this distance, or rather the space or void resulting from it, is called the capacity of bodies for containing caloric. Caloric is the cause of fluidity and of vapour.

Bodies which transmit caloric easily, are called conductors of caloric; and according to the power of doing this, they are termed good or bad conductors. Those which do not transmit heat at all, or with great difficulty, are called non-conductors. The best conductors of heat are metals, and the best non-conductors of fluids are water and air. Charcoal is also considered as a non-conductor. Heat is produced by collision, friction, chemical action, the solar rays, electricity, galvanism, &c. The instruments for measuring its intensity are called Pyrometers. See FIRE.

**CALX**, lime, but a dignified title for any powder remaining after burning a metal; and because in burning the metal imbibes oxygen, and the powder from it becomes heavier than the metal was before, all metallic calces are now-a-days called *oxides*, and rust is also an oxide.

**CAMBLET**, a stuff made of wool, hair, or silk, and sometimes of all these mixed.

**CAMBRIC**, a species of linen made of flax, very fine and white, deriving its name from Cambray, in France, where this cloth was first made.

**CAMEL** is the name given to a machine, employed by the Dutch for carrying vessels heavily laden over the sandbanks in the Zuyder-Zee. In that sea, opposite to the mouth of the river Y, about six miles from the city of Amsterdam, there are two sandbanks, between which is a passage called the Pampus, sufficiently deep for small vessels, but not for those which are large and heavily laden. On this account, ships which are outward bound take in before the city only a small part of their cargo, receiving the rest when they have got through the Pampus. And those that are homeward bound must, in a great measure, unload before they enter it. For this reason, the goods are put into lighters, and in these transported to the warehouses of the merchants in the city; and the large vessels are then made fast to boats by means of ropes, and in that manner towed through the passage to their stations.

Though measures were adopted so early as the middle of the sixteenth century, by forbidding ballast to be thrown into the Pampus, to prevent the further accumulation of sand in this passage, that inconvenience increased so much from other causes as to occasion still greater obstruction to trade; and it at length became impossible for ships of war, and others heavily laden, to get through it. About the year 1672 no other remedy was known than that of making fast to the bottoms of ships large chests filled with water, which was afterwards pumped out; so that the ships were buoyed up, and rendered sufficiently light to pass the shallow. By this method, which was attended with the utmost difficulty, the Dutch carried out their numerous fleet to sea in the above-mentioned year. This plan, however, gave rise soon after to the invention of the camel, by which the labour was rendered easier.

The camel consists of two half ships, constructed in such a manner that they can be applied below water, on each side of

the hull of a large vessel. On the deck of each part of the camel are a great many horizontal windlasses, from which ropes proceed through apertures in the one half, and, being carried under the keel of the vessel, enter similar apertures in the other, from which they are conveyed to the windlasses on its deck. When they are to be used, as much water as may be necessary is suffered to run into them; all the ropes are cast loose, the vessel is conducted between them, and large beams are placed horizontally through the port holes of the vessel, with their ends resting on the camel on each side. When the ropes are made fast, so that the ship is secured between the two parts of the camel, the water is pumped from them, by which means they rise, and float the ship with them. Each half of the camel is about 130 feet long, and 22 to 13 feet broad. The hold is divided into several compartments, that the machine may be kept in equilibrio while the water is flowing into it. A vessel drawing 15 feet water, can be made to draw only 11 by the camel; and ships of war of 100 guns, can be raised to pass without grounding the shallow banks of the Zuyder-Zee. The Russians\* employ similar machines to float vessels built in the Neva, over the intermediate sand-banks. Camels are also used at Venice.

**CAMELOPARDALIS.** The Camelopard is a modern constellation, that has been formed by Hevelius. Its boundaries and contents are: north by the pole of the world, east by Ursa Major and Lynx, south by Perseus and Auriga, and west by Perseus, Cassiopeia, and Tarandus; right ascension  $68^{\circ}$ , declination  $70^{\circ}$  north. It consists of 58 small stars, five of the fourth magnitude, and the rest smaller. The most conspicuous star is nearly on the Arctic Circle, on the near hind thigh. This constellation extends from Auriga to the North Pole, by which position it can be the better traced in the heavens.

**CAMERA LUCIDA**, or *Light Chamber*, a contrivance of Dr. Hook, to make the image of any object appear on a wall, in a light room, either by day or night. Dr. Wollaston has recently invented a portable instrument for drawing in perspective, to which he has given the name of *camera lucida*.

**CAMERA Obscura**, or *Dark Chamber*, in Optics, a machine or apparatus, so constructed, that principally by means of a convex glass, or a convex glass and plane mirror, the images of external objects are represented on a rough ground plane glass, white paper, or other surface, in the most vivid and distinct manner, with all their natural colours, motions, &c.

The use of the Camera Obscura is various: it assists very much in explaining the nature and rationale of vision; and hence by some it has been compared to an artificial eye. It exhibits the most striking and entertaining representations of objects of all descriptions, whether near or distant, in their true perspective; the colouring just and natural, their light and shadows correct, and all their motions and relative positions according to the original. By means of this instrument, a person, however unacquainted with drawing, may delineate objects with great facility and correctness; and to the skilful artist it will be found indispensably useful in comparing his sketches with the perfect representations given in the camera; and by observing his defective imitations, he may correct as much as possible his designs.

The theory of the Camera Obscura will be readily comprehended from the annexed figure, in which the object  $AB$  radiates through a small aperture,  $C$ , upon a white wall opposite to it, and if the place of radiation behind the aperture  $bca$  be dark, the image of the object will be painted on the wall, in an inverted position; for the aperture  $C$  being very small, the rays issuing from the point  $B$  will fall on  $b$ ; those from points  $A$  and  $D$  will fall on  $a$  and  $d$ ; wherefore, since the rays issuing from the several points are not confounded, they will by reflection exhibit its appearance on the wall. But since the rays  $AC$  and  $BC$  intersect each other in the aperture, and the rays from the lowest points fall on the highest, the situation of the object will of necessity be inverted.

If the wall where the object is delineated be parallel to it,  $ab : AB :: dC : DC$ , that is, the height of the image will be to the height of the object, as the distance of the image from the aperture is to the distance of the object from the same.

*To construct a permanent Camera Obscura.*—1. Darken a chamber, one of whose windows looks into a place set with various objects; leaving only a little aperture open in one shutter. 2. In this aperture fit a lens, either plano-convex, or convex on both sides, so as to be a portion of a large sphere. 3. At a due distance, to be determined by experience, spread a paper, or white cloth, unless there be a white wall for the purpose; for on this the images of the desired objects will be delineated invertedly. 4. If it be rather desired to have them appear erect, it is done either by means of a concave lens placed between the centre and the focus of the first lens; or by receiving the image on a plane speculum inclined to the horizon under an angle of  $45^{\circ}$ ; or by means of two lenses included in a drawtube, in lieu of one.—*Note.* If the aperture do not exceed the size of a pea, the objects will be represented, even though no lens be used.

That the images be clear and distinct, it is necessary that the objects be illuminated by the sun's light shining upon them from the opposite quarter; so that, in a western prospect, the images will be best seen in a forenoon; an eastern prospect, the afternoon; and a northern prospect, about noon: a southern prospect is the least eligible of any. But the best way is to have the lens fixed in a proper frame, on the top of a building, and made to move easily round in all directions, by a handle extended to the person who manages the instrument; the images being then thrown down into a dark room immediately below it, upon a horizontal round plaster of Paris ground: for thus a view of all the objects quite around may easily be taken in the space of a few minutes; as is the case of the excellent Camera Obscura placed on the top of the royal observatory at Greenwich, and with a very good one made by Holroyd of Leeds, in which the images are received on a table of more than six feet diameter.

A very simple portable Camera Obscura is represented in the annexed figure.  $ABCD$  is a small rectangular box, its length being about 20 or 24 inches, and its breadth about 10 inches. This box is closed on all sides, except the space  $EFGD$ , which is covered with a piece of ground glass, or transparent paper.

In the other end,  $AB$ , is a moveable tube,  $L$ , with a proper lens, and  $EIH D$  is a plane reflecting mirror (set at an angle of  $45^{\circ}$ ) which intercepts the rays  $Pp$ ,  $Qq$ , &c. proceeding from the object  $PQ$ , which are thence reflected upon the transparent screen  $EFGD$ , where the image of the object will be painted in its natural colours, but in an inverted position, as  $QP$ ; which, however, may be obtained erect, by the introduction of proper lenses in the tube  $L$ .—*Note.* That a shade is necessary to keep off the external light from the screen  $EFGD$ , which is commonly effected by having the box covered with a horizontal lid, under which are two wings which open at right angles to each side of it. Various other forms are given to this instrument.

**CAMP**, the ground on which an army pitch their tents. The Roman camp was a square, fortified with a ditch and parapet, and sometimes with walls of hewn stone, the tents themselves being formed of the same material.

**CAMPHORA**, or **CAMPHIRE**, a solid concrete substance extracted from the wood of the *laurus camphora*, is white, pellucid, unctuous to the touch, of a bitter aromatic taste, and smells like rosemary. As a medicine, it is useful in fevers, and all malignant distempers. From experiments on brutes, camphire is proved to be poisonous.

**CAMUS**, CHARLES STEPHEN LEWIS, a celebrated French mathematician, born at Cressey in Brie, August 25, 1699; died 1768, in the sixty-ninth year of his age.

**CANAL**, an artificial cavity in the earth, filled with water, to afford an easy, speedy, and cheap conveyance of goods, &c. in boats and vessels, from one part of a country to another.

\* It was introduced into Russia by Peter the Great, who obtained the model of one, when he worked in Holland as a common ship-carpenter.

Numerous circumstances contribute to facilitate or retard operations in canal-making; as, the situation and character of the ground and country, the vicinity and connexion of rivers. But the great business is the construction of the Locks, or BASONS, lined with walls of masonry, and built where the ground is hilly. The principle of a lock is this: Suppose a declivity of 10 feet in a length of 50 yards of ground. Then we must construct a bason, with a flood-gate, so that when filled with water from above, it may permit the vessel to pass on along the upper channel of the canal. A fall of 17 feet would require two locks; a fall of 26 feet, three locks, each having 8 feet 8 inches fall. All these operations proceed on the principle of continuing levels to given points, and by artificial means floating a boat some 8 feet perpendicularly, when we cannot proceed further with the level, in order that she may swim in another superior level, and *vice versa*.

The *Form of Locks*, should approach as nearly as possible to the figure of the boats that are to navigate them. The width must only exceed that of the boat by a space sufficient to work the gates. A rectangle is therefore the most natural figure, because it consumes the smallest quantity of water, is filled and emptied in the shortest time, and is constructed at the least expense.

The *Length, Depth, and Breadth of Locks*, ought also to be regulated by the form of the boats, which are generally long and narrow, with flat bottoms. Narrow lock-gates are more easily worked than broad ones, and narrow boats are more easily drawn than those which are wider and shorter.

*Reservoirs or Basins*, must be resorted to wherever a double lockage is unavoidable, from undulations in the line of navigation. These basins should collect the flooded waters from an ample surface of country, and be so high as to enable all the water they contain to be drawn into the summit of the canal. They should contract towards their lower extremity, so as to require a comparatively short embankment or head, which should be placed upon a substantial foundation. Reservoirs must not leak. The dimensions of their embankments must be regulated by the nature of the materials.

For the theory and practice of *Canal Cutting*, with *Plans of Locks* on the most celebrated canals, see INLAND NAVIGATION.

*CANAL Embankment*.—Since the pressure of any fluid is proportional merely to the depth below the surface, the strain borne by a sluice on the sides of a canal must increase uniformly from the top to the bottom. The centre of pressure is hence not in the middle, but at one-third of the entire altitude. To this point, therefore, if more strength be wanted, the additional prop should be applied.

If water be confined in a canal or basin by a wall or embankment, the thickness of the dike must increase regularly in proportion to its depth. The adhesion of any materials, or their resistance to a horizontal thrust, may be estimated as a certain proportion of their weight, commonly the half or the third part. Let *AB* be the height of the wall, and make its density to three times that of water, as *AB* to *BC*, and join *AC*, which will represent the proper slope. If the dike be composed of stones or bricks, the base *BC* must be at least equal to the altitude *AB*; but if it consists of earth, *BC* should be one half more. When the embankment is formed of earth, its side must not be perpendicular; it should form an inclined plane, not exceeding 35 degrees, or the *angle of repose*, lest the softened parts should slide down; the outside, being more solid, may be steeper.

The *Construction of Locks or Flood Gates*.—In canal navigation, a boat is raised from a lower to a higher level by a series of locks, a portion of the water somewhat exceeding the length of the vessel being enclosed at the sides by walls, and at both ends by masonry, and opposite flood-gates. As soon as it passes these gates, they are shut behind it; and a small lateral or superior sluice being opened, the water rushes into the

enclosure, and quickly mounts to the higher level, thus enabling the vessel again to proceed. A similar operation is performed at each successive lock. In descending the canal, the procedure is exactly reversed, the water contained in the series of enclosures being allowed to flow out, and thus lower by degrees the level of the boat.

The flood-gates are contrived to shut at a certain angle. If this angle be very acute, they sustain too great a pressure, and yet close feebly. Let *AC* and *BC* represent the flood-gates of a canal, which are opened by help of the extended arms *AE* and *BF*. When shut, the gate *AC* is pressed at right angles by the water, with a force as *AC* itself, which, from the principle of the lever, must exert a perpendicular effort at the end

*C*, as the square of *AC*. The thrust thence produced in the direction *AB* will be as  $AC \times CD$ , and will encounter an equal and opposite thrust from the gate *BC*. These two forces constitute the power which closes the gates. The force with which they are made to cohere, thus increasing with *AC* and *CD*, must augment rapidly when the angles *BAC* and *ABC* are enlarged, or their mutual inclination *ACB* becomes diminished.

If the angle *ACB* were very obtuse, those conjoined gates would, like a low roof, occasion a great thrust against the walls of the canal, or the centres of the gates at *A* and *B*.

The thrust in the direction *CA* might be shown to be  $\frac{AC^2 \times AD}{CD}$ .

It will hence be easy to determine the angle *ACB*, with the centres of the flood-gates which suffer the smallest strain; for

*AC* being constant,  $\frac{AC^2}{CD}$  must be a *minimum*. But this quantity is evidently the diameter of a circle circumscribing the triangle *ACB*; and since the least circle is that described about the point *C*, the angle *ACB*, at which the gates lock, should be a right angle.

**CANCER**, the *Crab*, ♋, is the first of the summer signs, which the sun enters, according to the fixed zodiac of the astronomers, on the 21st of June, introducing the first day of summer, and the longest day in the northern hemisphere,—the middle of day at the north pole, and the middle of night at the south pole. Agreeably to the moveable zodiac of nature, the sun enters this sign July the 19th. The sun, on June 21st, is at his greatest north declination, and is vertical to the tropic of Cancer. The earth, at this season, has entered Capricorn, and the sun is intermediate between the earth and the Celestial Crab. And on this account the north pole, which has now its greatest inclination to the sun, enjoys perpetual day. The tropic of Cancer is in the light from 5 in the morning till 7 at night; the parallel of London from a quarter before 4 till a quarter after 8, and the polar circle just touches the dark, so that the sun has only the lower half of his disk hid from the inhabitants on that circle, for a few minutes, about midnight. Thus do we account for summer in the northern regions of the earth.—The boundaries and contents of this constellation are: on the north by Lynx, east by Leo, south by Hydra, and west by Gemini. There are 83 stars in this sign, *viz.* seven of the 4th magnitude, and the remainder of inferior magnitudes.  $\alpha$  Canceris, near the eastern extremities of the great southern claw, having  $12^\circ 31' 6''$  north declination, and  $132^\circ 9' 20''$  of right ascension, rises nearly E.N.E. at London, and rises and culminates as follows: Meridian Altitude,  $51^\circ 0' 6''$ .

**CANDY**, or **SUGAR CANDY**, is sugar melted and crystallized six or seven times over, till it is rendered hard and transparent.

**CANES VENATICI**, the Hounds or Greyhounds, a northern constellation. These two dogs are farther distinguished by the names *Asterion* and *Chara*.

**CANICULAR**, the name formerly given to the constellation *Canis Major*; and the same was also sometimes applied to the star *Sirius*, whence the *Canicular Days*.

**CANICULAR Days**, or *Dog-Days*, denote properly a certain number of days which precede and follow the heliacal rising of *Canicular*, or the *Dog-star*, in the morning; which were formerly the days of the greatest heat. The ancients imagined that this star, rising as above, was the cause of the hot sultry weather common at that season, as well as of the distempers which usually followed them, and somewhat of a similar notion still prevails in many of the remote parts of this country, even to the present day. The dog-days were commonly reckoned at about forty; viz. twenty before, and twenty after the heliacal rising of *Sirius*; and in the almanacks, were usually accounted absolutely from this circumstance, which in consequence of the precession of the equinoxes brought them into the months of June and July, instead of July and August: an alteration, however, has been made in this respect within a few years; and they are now, without any regard to the rising of *Sirius*, accounted from July 3 to August 11; these being considered the hottest days of the year.

**CANICULAR Year**, denotes the Egyptian natural year; which was computed from one heliacal rising of *Canicular* to another.

**CANIS MAJOR**, the *Great Dog*, a constellation in the heavens, is fabled to have been one of Orion's hounds; the other was *Canis Minor*; for Orion, Boötes, and *Sagittarius* were denominated Hunters among the constellations: but some writers of ancient story tell us, that the sagacious *Mæra*, which discovered to Erigone the burial place of her murdered father *Icarus*, was changed into one of the celestial dogs. The true account of *Canis Major*, and which has obtained the credence of mankind, is, that it represents the Egyptian god *Anubis*. The people of Egypt judged of the swelling of the Nile by the rising of the brilliant in this constellation, and hence they represented it by the figure of a dog, this animal being the most watchful and faithful of the brute creation. The *Dog Star*, *Latrator Anubis*, is vertical on the 30th of June, when the Nile overflows. Indeed, *Canis Major* seems to have had the same relation to the Nile that *Cerberus* had to the sun; and *Porphyry*, who was well versed in the mythology of the ancients, says, *Cerberus* was described with three heads, in reference to the rising, the meridian altitude, and the setting of the sun. The triple bust of the Hindu deity exhibits to us in one compound figure an hieroglyphic of the solar god, having a perfect resemblance to *Cerberus*. At night, and in the west, the sun is *Vishnou*; he is *Brahma* in the east, and in the morning; from noon to evening he is *Seeva*.—The boundaries and contents of this constellation are: on the north by *Monoceros*, east and south by *Argo Navis*, and west by *Columba Noachi* and *Lepus*. In this constellation there are sixty-four stars, of which the brilliant *Sirius* is of the 1st magnitude, two of the 2d, four of the 3d, four of the 4th, &c. *Sirius* in size and colour resembles the planet *Jupiter* more than any of the other fixed stars, and has thence been supposed to be nearer our earth than *Arcturus*, *Capella*, *Vega*, *Spica*, or *Aldebaran*. The right ascension of *Sirius* for 1820 was  $99^{\circ} 18' 10''$ ; and the declination  $16^{\circ} 28' 11''$  south. It rises at London on the S. E. by E.  $\frac{1}{4}$  E. point of the compass nearly; and rises and culminates as in the following table, for the 1st of every month: Meridian Altitude  $22^{\circ} 9' 49''$ .

**CANIS MINOR**, the *Little Dog*, is said to be the type of one of the beagles in Orion's pack, or it is from the kennel of Boötes, or it is the sagacious-cur y'cleped *Mæra*. The star

*Procyon*, in *Canis Minor*, comes to the meridian about 50 minutes later than *Sirius*, but it rises to Egypt at the same time with the brilliant in the *Great Dog*, but 25 degrees further east. Now, whoever attends to the observations made by the ancients upon *Sirius*, must be satisfied that *Procyon* had its boundaries assigned from its being an attendant of the *Great Dog*, so famous in all that regarded the rising, overflowing, and decrease of the Nile. The Egyptians have introduced the astronomical symbols in pairs; thus we have two rivers, two serpents, two bears, two fishes, &c.; and there is very strong collateral evidence to prove that their whole territory was partitioned out agreeably to those symbols. With respect to the symbol before us, there seems little doubt that *Canis Minor* rising in conjunction with the *Great Dog*, but coming later to the meridian, as if assigning the other the point of honour, and then declining in the west above an hour later than its companion, was a fit emblem of that fidelity which *Latrator Anubis* was feigned to evince towards *Isis* and *Osiris*. One of the celestial dogs may thence have reference to the *arkite worship*, and the other to the *solar superstition*.—The boundaries and contents of *Canis Minor* are: on the north by *Gemini*, east by *Hydra*, and south and west by *Monoceros*. There are fourteen stars in this constellation, according to the *Britannic Catalogue*, viz. one of the 1st magnitude, one of the 2d, one of the 4th, &c.  $\alpha$  *Procyonis*, of the 1st magnitude, in *Canis Minor*, rises at London, on the east by north point of the compass nearly; its declination north is  $5^{\circ} 46'$ , and its right ascension  $112^{\circ} 27' 53''$ . It rises and culminates on the first day of each month, as follows: Meridian Altitude  $44^{\circ} 15'$ .

The situation of  $\alpha$  (*Procyon*) is easily found when it is above the horizon at night, for it always forms a triangle with *Betelgeux*, *Rigel*, and *Sirius*; and it comes to the meridian about four minutes after *Castor*, and about one minute before *Pollux*.

**CANNON**, a military engine for throwing ball, first used in the battle of Cressy, in 1346, by king Edward; or, mounted in battery on the decks of ships, to fire balls on other ships.

The principal parts of a cannon are, 1st. The breech, and its button or cascabel, called by seamen the pomelion. The breech is generally understood to be the solid metal from the bottom of the concave cylinder to the cascabel, which is the extremity of the cannon opposite to its muzzle. 2d. The trunnions, which project on each side like arms, and serve to support the cannon near the middle of its length, holding it almost in equilibrio. As the metal is thicker at the breech than towards the mouth, the trunnions are placed nearer to that end than the other. 3d. The bore or caliber is the interior or concave cylinder, wherein the powder and shot are lodged when the cannon is charged or loaded. The entrance of the bore is called the mouth or muzzle. The other parts are as follow: The length; the 1st reinforce; the 2d reinforce; the chase; the ventfield; the chase girdle; the breech mouldings; the swelling of the muzzle; the base ring and ogee; the vent astragal and fillets; the 1st reinforce ring and ogee; the 2d ditto, ditto; the chase astragal and fillets; the muzzle ditto, ditto; the muzzle mouldings; the swelling of the muzzle.

The diameter of the ball is always somewhat less than the bore of the piece, that it may be discharged with the greater ease, and not damage the piece by rubbing it too forcibly in its passage, and the difference between these diameters is called the windage of the cannon. The length of any cannon is always reckoned from the hind part of the base ring, or beginning of the cascabel, to the extremity of the muzzle. The second reinforce begins at the same circle where the first terminates, and the chase at the same circle where the second reinforce ends.

The first reinforce, therefore, includes the base ring, the ogee nearest thereto, the vent-field, the vent-astragal, and

first reinforce ring. The second reinforce contains the ogee next to the first reinforce ring, and the second reinforce ring. The chase comprehends the ogee nearest to the second reinforce ring; the chase girdle and astragal, and the muzzle and astragal. The trunnions are always placed on the second reinforce, so that the breech part of the cannon may weigh something more than the muzzle part, to prevent the piece from starting up behind when it is fired.

A variety of experiments made with great care and accuracy, prove that the powder, when on fire, possesses at least 4000 times more space than when in grains. Therefore, if we suppose that the quantity of powder with which a cannon is charged, possesses one-fourth of a cubical foot in grain, it will, when on fire, occupy the space of about 1000 cubical feet. The same experiments evince also, that the powder, when inflamed, is dilated equally round its centre. One grain of powder fired in the centre of different concentric circles, round which grains of powder are placed, shall therefore set fire to all those grains at once. From this principle, it necessarily follows, that powder when fired in a cannon, makes at the same instant an equal effort on every part of the inside of the piece, in order to expand itself about its centre every way. But as the resistance from the sides of the piece turns the action of the powder so as to follow the direction of the bore of the cannon, when it presses upon the ball, so as to force it outwards, it presses also on the breech of the cannon, and this gives the piece a motion backwards, that is called the recoil, which is restrained by the breeching, and the convexity of the decks. The recoil in some degree diminishes the action of the powder upon the shot. But this cannot be avoided; for if the carriages were fixed so as not to give way to this motion, the action of the powder, or the effort that causes the recoil, would tear them to pieces in a very short time.

The metal of the cannon is not equally thick in all parts, but is in some measure proportioned to the force of the powder which it is to resist. At the breech, where the effort is strongest, the thickness of the metal is equal to the diameter of the corresponding shot. At the first reinforce, when this begins to slacken, the thickness is somewhat less than at the breech; at the second, where the force is still further diminished, the thickness is more reduced than at the first; and by the same rule, the chase has less thickness than the second reinforce. The thickness of the chase gradually diminishes from the trunnions to the mouth of the piece; so that if a cannon was without a cascabel, trunnion, and mouldings, it would exactly resemble the frustum of a cone, or a cone deprived of the small end.

Cannons are charged by putting down into the bottom first a quantity of powder, one-third or one-half the weight of the ball. This is done with an instrument termed a ladle, which is a kind of cylindrical spoon, generally made of copper, and fixed to the end of a staff called its handle. Upon the powder is put in a wad of rope yarn, formed like a ball, which is pressed down upon the powder with an instrument called a rammer; upon this wad is put the ball or shot, and to secure it in its proper place, another wad is firmly pressed down upon it, which operation is called ramming home the wad and shot. The touch-hole of the piece is then filled with powder, from the upper part of which a little train is laid that communicates with it. The use of this train is to prevent the explosion of the powder from operating directly upon the instrument employed to fire the piece, which, in that case, might be forced out of the hand of the gunner.

In the modern pieces, a little gutter or channel is framed on the upper part of the breech, to prevent the train from being dispersed by the wind. This channel reaches from the touch-hole to the base ring.

The cannon being pointed to its object, or the place it is intended to strike, the train is fired, and the flame immediately conveyed to the powder in the touch-hole, by which it is further communicated to that in the piece. The powder being kindled, immediately expands, so as to occupy a much greater space than when in grains, and thus dilated, it makes an effort on every side to force itself out. The ball making less resistance than the sides of the piece, upon which the powder presses at the same time, is driven out by its whole effort, and acquires

that violent motion which is well known to the world. After firing, there is a sponge used to clean the piece, and extinguish any sparks that may remain behind. In the land service, the handle of the sponge is a long wooden staff; but in ships of war, this handle, which usually contains the rammer at its other end, is a piece of rope well stiffened by spun-yarn, which is for this purpose firmly wound about it. By this convenience the rammer becomes flexible, so that the piece is charged within the ship, as the person who loads it may bend and accommodate the length of the rammer to the distance between the muzzle and the ship's side; being at the same time sheltered from the enemy's musketry, to which he would be exposed, in using a wooden rammer without the ship. To sponge a piece, therefore, is to introduce this instrument into the bore, and thrusting it home to the further end thereof, to clean the whole cavity.

The worm, of which there are different kinds, is used to draw the charge when necessary. The bit, or priming-iron, is a kind of large needle, whose lower end is formed into a gimblet, serving to clear the inside of the touch-hole, and render it fit to receive the prime. The lint-stock is a kind of staff, about three feet long, to the end of which a match is occasionally fastened to fire the piece.

The following is Mr. Robin's scheme for augmenting the force of the present sea-batteries, on this plain principle—that all ship-guns should be cast upon the model of the 32-pounders, measuring by the diameter of the respective bullet; so that for each pound of bullet there should be allowed one hundred and two-thirds of metal only. The advantages of this scheme will appear by the following comparison of the weight of the present pieces, with their weight proposed by this new fabric.

| Pounders. | Weight now in Hundreds. | Weight by New Fabric |
|-----------|-------------------------|----------------------|
| 24 .....  | 48 to 46 .....          | 40                   |
| 18 .....  | 41 to 39 .....          | 30                   |
| 12 .....  | 34 to 31 .....          | 20                   |
| 9 .....   | 29 to 26 .....          | 15                   |
| 6 .....   | 34 to 18 .....          | 10                   |

Hence it appears that the 24-pounders will be eased of 6 or 8 cwt. of useless metal; and instead of guns of inferior caliber now used, much larger ones of the same weight may be borne especially when it is remembered that this computation exceeds even the present proportion of the 32-pounders; so that from the above projected 18-pounders, for instance, 2 or 300 weight may be safely taken. The changes then proposed by the author are these:—

| Pounders.            | Hundreds. | Pounders.      | Hundreds. |
|----------------------|-----------|----------------|-----------|
| For { 6 of 24 and 18 |           | New { 12 of 20 |           |
| { 9 ..... 29 and 26  |           | { 18 ..... 28  |           |
| { 12 ..... 34 and 31 |           | { 24 ..... 40  |           |
| { 18 ..... 41 and 39 |           |                |           |

The nine-pounders lately cast, being still lighter than what is here represented, they may, perhaps, be only transformed into 12-pounders; but this will be a very great addition of strength, and the 12-pounders thus borne, will be considerably lighter than the smallest nine-pounders now in use. The weight of the present three-pounders is not remembered exactly by the author, but he doubts not that they are heavier than the proposed six-pounders, and may therefore be changed for them. And the author believes, that one-fourth or one-fifth of the weight of the bullet in powder, if properly disposed, is abundantly sufficient for every species of ship's guns.

**Boring CANNON.** (See PL. OIL MILL.)—Till within a few years, iron cannon were cast with a cylindrical cavity, nearly of the dimensions of the caliber of the piece, which was afterwards enlarged to the proper caliber by means of steel-cutters fixed into the dog-head of a boring bar-iron. Three equidistant side-cutters were requisite to preserve the caliber straight and cylindrical; and a single cutter was used at the end of the bar to smooth the breech of the piece. In boring cannon cast hollow, the piece was fixed upon a carriage that could be moved backwards and forwards in a direct line with the centre of a water-wheel; in this centre was fixed the boring-bar, of a sufficient length to reach up to the breech of the piece, or more properly to the further end of the caliber. The carriage with the piece being drawn backwards from the centre of the water-

wheel to introduce the boring and finishing bars and cutters, it is then pressed forwards upon this bar by means of levers, weights, &c. and the water-wheel being set going, the bar and fullers are turned round, and clean out and smooth the caliber to its proper dimensions.

Experience at last pointed out many inconveniences arising from the method of casting guns *hollow*, and widening the calibers by boring bars; but chiefly, that all guns cast hollow became more or less spongy where they ought to have been most compact; and numberless cavities also were created round the cores, from stagnated air generated in them, which were too deep to be cut out by the boring. To remedy these defects, iron cannon as well as brass is now universally cast solid, by which means the column of metal is greatly enlarged, and the grain more compressed; and the contraction becomes in the heart of the column, and consequently is cut out by the perforation for the caliber.

Guns are bored out of the solid reversely from the hollow method. The piece A is placed upon two standards BB, by means of two journeys, turned round by machinery; the breech D being introduced into the central line of the wheel, with the muzzle towards the sliding carriage E, which is pressed forwards by a ratch F, and weights, in the same way as the gun carriage was in hollow-boring. Upon this sliding carriage is fixed, truly horizontal and central to the gun, the drill-bar G, to the end of which is fixed a carp's-tongue drill or cutter H; which, being pressed forward upon the piece whilst it is turning round, perforates the bore, which is afterwards finished with bars and cutters as the hollow guns were.

The machinery for boring of ordnance is sometimes put in motion by a steam-engine; and in this way, from 18 to 24 great guns have been boring at the same time; the borer in each piece being brought up to its proper place in the gun, by a lever and weights. In this method of bringing up the borer, the pressure may always be made equable, and the motion of the borer regular; but the disadvantage is, that without due attention, the borer may work up too far towards the breech, and the piece be spoiled.

"In the Royal Arsenal at Woolwich," says Dr. Gregory, "only one piece is bored at a time in the same mill: the gun to be bored lies with its axis parallel to the horizon, and in that position is turned round its axis by means of wheel-work, moved by one or more horses. The borer is laid, as above described, in the direction of the axis of the gun, and is incapable of motion in any direction except that of its length; and in this direction it is constantly moved by means of a small rack-wheel, kept in proper motion by two men, who thus make the point of the borer so to bear against the part of the gun that is boring, as to pierce and cut it. The outside of the gun is smoothed at the same time by men with instruments fit for the purpose, whilst it turns round, so that the bore may be exactly in the centre of the metal. In this way the boring is performed with great nicety, the guns scarcely ever failing in the examination. But in these mills the horses work to great disadvantage, the diameters of the walks in which they move being far too small." See GUN, POWDER, GUNNERY.

CANNONADE, the application of artillery to the purposes of war, directing the shot against some remote object, as a ship, a fortress, &c. which it is designed to destroy or capture. In the marine, a large vessel may be considered as a combination of floating batteries, and hence, her efforts must be greatly superior to those of a fortress on land; but this is not always the case, for on some particular occasions her situation may be extremely dangerous, and her cannonading ineffectual. There are several circumstances in which her superiority consists, *viz.* the power of bringing her different batteries to converge to one point; of shifting the line of her attack so as to do the greatest possible execution against the enemy, or to lie where she will be the least exposed to his shot; and chiefly because, by employing a much greater number of cannon against a fort than it can possibly return, the impression of her artillery against stone walls soon becomes decisive and irresistible. Besides these advantages in the attack, she is also greatly superior in point of defence; because the cannon shot passing with rapidity through her sides, seldom do any execution out of the line of their flight, or occasion much mischief

by their splinters; whereas, they very soon shatter and destroy the faces of a parapet, and produce incredible havoc amongst the men by the fragments of the stones, &c. A ship may also retreat when she finds it too dangerous to remain longer exposed to the enemy's fire, or when her own fire cannot produce the desired effect. Finally, the fluctuating situation of a ship, and of the element on which she rests, render the efforts of shells very uncertain, and altogether destroys the effect of the ricochet or rolling and bounding shot, whose execution is so pernicious and destructive to a fortress in land engagements; both of which, however, a ship of war may apply with great success. On the contrary, the chief inconvenience to which she is exposed, is, that the low-laid cannon in a fort, near the brink of the sea, may strike her repeatedly on or under the surface of the water, so as to sink her before her cannonade can have any considerable efficacy.

CANOE, a sort of Indian boat, or vessel, formed of the trunk of a tree hollowed, and sometimes of several pieces of the bark fastened together; they are used on various occasions, as fishing, passage, trade, &c. and are of several sizes, according to the different uses for which they are designed in different countries. They are generally rowed with paddles, instead of oars, which are pieces of light wood, nearly resembling a corn shovel, and instead of moving the paddle horizontally like an oar, they row perpendicularly; the small ones are very narrow, having only room for one person in breadth, and eight or ten lengthways. They very easily carry sail, unless when going before the wind, and their sails are made of a sort of rushes or silk grass; they seldom have any rudder, the want of which is supplied by a dexterous management of the hind oars. The Indians who navigate them are very expert in rowing uniformly, and in balancing them properly with their bodies, which would be difficult for a stranger to do, however well accustomed soever to the conducting of our boats, on account of the extreme lightness of the canoes, and their aptness to be overturned. The Negroes in Guinea, and even many in the East Indies, use them. The American Indians, when they are necessitated to land on account of a waterfall or other occasion, carry their canoes on their heads or shoulders, till they arrive at some place where they may again be launched. The canoe of the Esquimaux Indians in Labrador has a light wooden frame, and the shell, instead of a plank, is made with seal skins sewed together, which are not only extended round the bottom and sides, but likewise over the top, forming a complete deck, and having only one opening conveniently framed, and situated to admit the Indian into his seat. A flat hoop is fitted to this hole rising about four inches, to which the surrounding skin is sewed. The Indian's calf-skin jacket being of a proper length, he can occasionally bind the skirt of it round the outside of this hoop, by which means he keeps the canoe free from water, and is enabled to pursue his game far from land, and in stormy seas. His paddle is about 10 feet long, light, and flat at each end, with which he both rows and steers with great velocity and exactness.

CANON, in Arithmetic, Geometry, &c. a general rule for resolving all cases of the same kind: this word is now seldom used; we say instead of it, method or formula.

CANT TIMBERS, those timbers which are situated at the two ends of a ship. They derive their name from being canted or raised obliquely from the keel, in contradistinction to those whose planes are perpendicular to it. The upper ends of those on the bow or fore part of the ship are inclined to the stem, as those in the after or hind part incline to the stern-post above.

CANTATA, in Music, a song or composition intermixed with recitatives, airs, and different movements, chiefly intended for a single voice.

CANVASS, a strong kind of cloth, of which the sails are made. Among Painters, canvass is the cloth on which they usually draw their pictures, having first stretched it in a frame of deal wood.

CAOUTCHOUC, elastic resin, or Indian rubber, a substance produced from an American tree, has been already explained. This substance oozes out of the trees by incisions made in them, and has the appearance of milk, and it is thickened merely by exposure to the air.

CAOUTCHOUC Gum is thus made:—Take one pound of spirit

of turpentine, and one pound of the gum, cut into small pieces. (A knife dipped in cold water cuts this elastic stuff easily.) Pour the turpentine into a long-necked matrass, or fire-proof bottle, which must be placed in a sand bath; throw in the gum, bit by bit, till it all dissolves. Add now a pint of nut or linseed oil, or oil of poppies; then let the whole boil for a quarter of an hour, and the preparation is finished. This is an excellent but expensive varnish for air-balloons.

**CAP**, a strong thick block of wood, having two large holes through it, the one square, the other round, used to confine two masts together, when one is erected at the head of the other, in order to lengthen it. The principal caps of a ship are those of the lower masts, which are fitted with a strong eye-bolt on each side, wherein to hook the block by which the topmast is drawn up through the cap. The breadth of all the caps is equal to twice the diameter of the topmast, and the length to twice the breadth. The thickness of the main and forecaps is half the diameter of their breadths; the mizencap three-sevenths, and the topmast caps two-fifths of their respective breadths. In the same manner as the topmast slides up through the cap of the lower mast, the top-gallant-mast slides up through the cap of the topmasts.

**CAPILLARY ACTION**. The suspension of a slender column of water in the interior ring of a glass tube, is the popular explanation of capillary action, or attraction.

**CAPILLARY Tubes**. One of the most singular phenomena of these tubes is, that if you take several of them of different sizes, open at both ends, and immerse them a little way into water, or any other fluid, it will immediately rise in the tubes to a considerable height above the surface of that into which they are immersed; these heights varying nearly in a reciprocal proportion of the diameters; the greatest heights, according to Dr. Hook, being about 21 inches. The heights, however, are not the same for all fluids, some standing considerably higher or lower than others: and with regard to quicksilver, it does not rise in their tubes at all, but, on the contrary, stands lower in the tube than in the vessel into which the tube is immersed, and that so much the more as the diameter is smaller. Another phenomenon of these tubes is, that such of them as will naturally discharge water only by drops, when electrified yields it in a perpetual stream. Various hypotheses have been advanced to account for the ascent of fluids in capillary tubes; some attributing it to the attraction of the glass upon the upper surface of the fluid, others again, to the diminished pressure of the air on the fluids in the tube, &c. The cause of the phenomenon is satisfactorily accounted for thus: It is a fundamental property of fluids, that any force impressed in one direction may be propagated equally in every direction. The tendency of the fluid, then, to approach the glass, will occasion it to spread over the internal cavity of the tube, and consequently to mount upwards.

Capillary action is not confined to glass tubes, but is exerted among all substances perforated by pores, or subdivided by fissures or interstices. Hence, the excretory vascular systems of plants and animals; the ascent of humidity through rocks, earth, &c.; the lymph or perspiration exuded by the pores of the human skin, the leaves of trees, plants, and grasses—pores that exceed not the ten-thousandth part of an inch: and while plants retain their vegetating principle, the humidity they draw from the earth by means of their roots, is constantly exhaled into the atmosphere, and as constantly supplied by the ascent of sap from the roots.

**CAPRA**, the name of a small Northern Constellation, consisting of three stars.

**CAPRICORN**, the *Goat*, a southern constellation, and the tenth sign of the zodiac, denoted by the character  $\varphi$ , being intended for the representation of the goat's horns. It is the first of the winter, and the fourth of the southern signs, according to the fixed and intellectual zodiac; and the sun enters it on the 21st of December, which is the time of the winter solstice, when the earth makes the transit from Gemini to Cancer. But the visible and moveable zodiac places this sign in the station of Aquarius, and the sun enters it about the 16th of January. At the period of the winter solstice, the sun being vertical to the tropic of Capricorn, the southern hemisphere enjoys the same light, &c. which the northern hemisphere

enjoyed on the 21st of June, when the sun was vertical to the tropic of Cancer. It is then the middle of day at the south pole, and the middle of night at the north pole.—The boundaries and contents of Capricorn are: on the north and east of Antinous and Aquarius, on the south by Piscis Australis, and on the west by Sagittarius. It contains 51 stars, three of which are of the 3d magnitude, three of the 4th, &c. The following table shews the time when  $\alpha$ , a star of the third magnitude, in the Goat's forehead, rises and culminates for the first day of each month in the year. This star rises nearly on the E. S. E.  $\frac{1}{2}$  E. point of the horizon, at London; its right ascension is  $302^{\circ} 0' 51''$ , and its declination  $13^{\circ} 5' 39''$  south: Meridian Altitude  $25^{\circ} 23' 21''$ .

**Tropic of CAPRICORN**, a small circle of the sphere parallel to the equinoctial, passing through the beginning of Capricorn, or the winter solstice, or point of the sun's greatest southern declination.

**CAPRIOLES**, in the Manage, leaps which a horse takes in the same place without advancing, in such a manner, that when he is at the height of the leap, he jerks out with his hinder legs even and near. The common name of this exercise is, among dragoons, *the pillared horse*, because the animal, to work well at caprioles, is put between two pillars, and taught to raise first his fore quarters, and then his hind quarters, while his fore ones are yet in the air.

**CAPSTAN**, or **CAPSTERN**, a great piece of timber, in the shape of a cone, usually placed behind the windlass of a ship, to weigh anchors, hoist up or strike down topmasts, strain ropes, or heave any heavy bulky thing on board of a ship, as in the upper figure.

The advantages of simplifying machinery are well exemplified in the second capstan, which unites great strength and simplicity. It is represented in the lower figure, where A D is a compound barrel composed of two cylinders of different radii. The rope D E C is fixed at the extremity of the cylinder D; and after passing over the pulley E, which is attached to the load by means of the hook F, it is coiled round the other cylinder D, and fixed at its upper end. The capstan bar A B urges the compound barrel C D about its axis, so that while the rope coils round the cylinder D it unwinds itself from the cylinder C. Let us suppose, that the diameter of the part D of the barrel is 21 inches, while the diameter of the part C is only 20 inches, and let the pulley E be 20 inches in diameter. When the barrel A D, therefore, has performed one complete revolution by the pressure exerted at B, 63 inches of rope, equal to the circumference of the cylinder, will be gathered upon the cylinder D, and 60 inches will be unwound from the cylinder C. The quantity of wound rope, therefore, exceeds the quantity that is unwound by  $63 - 60 = 3$  inches, the difference of their respective perimeters; and the half of this quantity, or  $1\frac{1}{2}$  inches, will be the space through which the load or pulley E moves by one turn

of the bar. If a simple capstan of the same dimensions had been employed, the length of rope coiled round the barrel would have been 60 inches; and the space described by the pulley, or load to be overcome, would have been 30 inches. Now, as the power is to the weight as the velocity of the weight is to the velocity of the power, and as the velocity of the power is the same in both capstans, the weights which they will raise will be as  $1\frac{1}{2}$  to 30. If it be wished to double the power of the machine, we have only to cover the cylinder C with lathes a quarter of an inch thick, so that the difference between the radii of each cylinder may be half as little as before; for it is obvious that the power of the capstan increases as the difference between the radii of the cylinders is diminished. As we increase the power, therefore, we increase the strength of our machine, while all other engines are proportionably enfeebled by an augmentation of power. Were we, for example, to increase the power of the common capstan, we must diminish the barrel in the same proportion, supposing the bar A B not to admit of being lengthened, which will not only diminish its strength, but destroy much of its power by the additional flexure of the rope.—This capstan may be easily converted into a crane, by giving the compound barrel a horizontal position, and substituting a winch instead of the bar A B. The superiority of such a crane above the common ones does not require to be pointed out; but it has this additional advantage, that it allows the weight to stop at any part of its progress, without the aid of a ratchet wheel and catch, because the two parts of the rope pull on the contrary sides of the barrel. The rope indeed which coils round the larger part of the barrel acts with a larger lever, and consequently with greater force, than the other; but as this excess of force is not sufficient to overcome the friction of the machine, the weight will remain stationary in any part of its path.

The principle on which the preceding capstan is constructed, might be applied with great advantage when two separate axles A C, B D are driven by means of the winch H and the wheels B and A, as in the annexed figure. It is evident, that when the winch is turned round in one direction, the rope *r* is unwound from the axle B D; the wheel B drives the wheel A, so that the axle A C moves in a direction opposite to that of B D, and the rope is coiled round the axle A C. If the wheels A, B, are of the same diameter and the same number of teeth, the weight W will be stationary, as the rope wound about one axle will be always equal to what is unwound from the other. If the wheels have different diameters, or different numbers of teeth, the quantity of rope wound round the one axle will exceed what is unwound from the other, and the weight will be raised.

CAPUT DRACONIS, the *Dragon's Head*, a name given by some to the star  $\alpha$ , Draconis, in the head of that constellation.

CARDAN, JEROM, a celebrated mathematician, physician, and astrologer of the sixteenth century, born in Italy Sept. 24, 1501, and died at Rome in Sept. 1575. As an astrologer, he was invited to England in order to cast the nativity of Edw. V. as he had already done that of his own; which latter not being precisely correct as to the time of his death, he is said to have starved himself for the honour of the science; viz. that his living might not discredit his art. Hudibras alludes to Cardan's pretended astrological skill in the following lines:—

“Cardan believes great states depend  
Upon the tip of the Bear's tail's end;  
And as she winks it t'wards the sun,  
Strews mighty empires up and down.”

CARDINAL POINTS, in Geography and Navigation, the four principal points of the compass; viz. east, west, north, and south. The term is derived from *cardo*, a *hinge*, being that on which all the others turn or depend.

CARDINAL Signs, are those at the four quarters, or the equi-

noxes and solstices; viz. the signs Aries, Libra, Cancer, and Capricorn. *Cardinal Winds*, those that blow from the cardinal points.

CARDIOIDE, (see the annexed figure,) the name of a curve so denominated by Castilliani, from its resemblance to a heart, *καρδία*: the construction of which is as follows:—Through one extremity A, of the diameter AB, of the circle APB, draw a number of lines APQ, cutting the circle in P P, &c. upon the set off PQ, equal to the diameter AB; then the curve passing through all the points Q, Q, &c. is termed the Cardioide. From this generation of the curve, is readily reduced its principal properties; viz. that every where . . . . . PQ = AB

$$CQ \text{ or } QQ = Aa = 2AB$$

$$AQ = AB = AP$$

P always bisects QQ.

CAREENING, the operation of heaving a ship down on one side, by the application of a strong purchase to her masts, which are properly supported for the occasion, to prevent their breaking with so great a strain; by which means one side of the bottom, being elevated above the surface of the water, may be cleansed or repaired. When a ship is laid on a careen every thing is taken out of her; but this operation is now nearly superseded by sheathing the ships with copper, whereby they keep a clean bottom for several years. A ship is also said to careen, when she inclines to one side at sea by a press of sail.

CARLINGS, short pieces of timber ranging fore and aft from one deck beam to another, into which their ends are mortised; they are used to sustain and fortify the smaller beams of the ship.

CARMINATIVES, Medicines used in colics, or other flatulent disorders, to dispel wind.

CARMINE. See COLOUR MAKING.

CARNATION, or Clove Pink, an agreeable flower, valued for its pleasant flavour and lovely leaves. It is said the flowers of this plant, reduced to a decoction, have cured many malignant fevers, &c.

CARNELIAN, in Natural History, a precious stone, red, yellow, or white, usually brought from the East Indies.

CAROTIDS, in Anatomy, two arteries of the neck, which convey the blood from the aorta to the brain; one called the right, and the other the left carotid.

CARPENTER, a person who practises carpentry.

CARPENTER of a ship, is an officer appointed to examine and keep in order the frame of the ship, together with her masts, yards, boats, and all other wooden machinery, likewise the stores committed to him by indenture from the surveyor of the dock yard. It is the carpenter's duty in particular, to keep the ship tight, for which purpose he ought frequently to review the decks and sides, and to caulk them when it is found necessary. In the time of battle, he is to examine up and down with all possible attention in the lower apartments of the ship, to stop any holes that may be made in the sides by shot, with wooden plugs, provided of several sizes for that purpose.

CARPENTRY, the art of building, framing, &c. See JOINER.

CARRIAGE of a Gun, is a strong frame of wood fixed on four solid wheels, or trucks, on which the cannon is placed: its chief parts are as follow:—1. The sides or cheeks; 2. the axletrees; 3. the trucks or wheels; 4. the transom; 5. the sole or bottom; 6. the bed; 7. the quoin. These are all of wood. 8. the cap-squares, or clamps; 9. the eye-bolts; 10. joint bolts; 11. the transom bolt; 12. the bed bolt; 13. hind axletree bolts; 14. the breeching bolts; 15. loops, or eye-bolts, to which the gun tackle are hooked; all of iron.

The Construction of Wheel Carriages is one of the most important branches of mechanical science, whether we consider their general use, or the numerous lives which are daily risked in travelling by this mode of conveyance. We will, therefore, in the first place, direct our readers' attention to the wheels of these vehicles. Every wheeled carriage consists of two or more wheels, generally four: but the fore wheels of our wag-

gons are unaccountably small, and it is not uncommon to see carts moving upon wheels scarcely two feet diameter. We know that the convenience of turning is urged as the reason for diminishing these wheels, and we allow, that much address is requisite in the crowded and narrow lanes and courts of London, to turn unwieldy waggons, drawn by four huge horses. The disadvantages of small wheels will be obvious from this: Suppose CDE (as in the annexed figure,) a wheel, and FG an obstacle over which it is to be moved by a force P, acting in the direction

in the direction AH; join AF, and draw Fm, Fn, perpendicular to CA and AH. The weight D of the wheel is evidently the weight to be raised, and may be represented by W acting at the point A in the vertical direction AC. We may now consider AF as a lever, whose fulcrum is F, and there will be an equilibrium when the force P is to the force W, as the perpendicular Fm is to the perpendicular Fn. And since Fm represents the mechanical energy of the power P to turn the wheel round F, it is obvious, that when FG is equal to the radius of the wheel, (as in this case it is only 12 inches,) the weight P, however great, has no power to move it over the obstacle, for when FG is equal to AC, Fm will vanish, that is, the obstacle being as high as the axletree of the wheel, it could never surmount it. In other words, Fm is now equal to O, which, if multiplied by P, no matter what the weight of P may be, the product is O. How very difficult then must it be for the best horses to tug an unwieldy waggon with fore wheels only 14 inches in radius. Hence, since the power of a wheel to overcome stones, rubbish, and all manner of resistances in the road, increases with its diameter, the advantages of large wheels for overcoming such resistances must be apparent. But there are some circumstances, which, independent of their weight and expense, prescribe limits to the size of wheels. A wheel should never exceed 4½ feet diameter, that is, the height of a horse's shoulder where the traces are fixed to the collar.

With respect to the shape of the wheels, every mechanic would place the spokes perpendicular to the axletree, if he were not prejudiced, by apprenticeship, to the pretended advantages of concave or dishing wheels, or those which have inclined spokes, as in the annexed figure, PA, PB, and conical rims Ar and Bs. It is alleged, this wheel renders the carriage less liable to be overturned, by extending the base; that it is stronger; that it hinders the fellies from rubbing against the sides of the cart, &c. &c. But the concave dishing wheel is more expensive than the other, more injurious to the roads, more liable to be broken by accidents, and less durable than the wheel with spokes perpendicular to the naves. Look at the figure, and you will see that the whole of the pressure which the wheel AB sustains, is exerted along the inclined spoke, Ps therefore acts obliquely upon the level ground nD, whether the rims with their tire irons are conical or cylindrical. But when the spokes are perpendicular to the nave, as pn, and when the rims mA, nB, are cylindrical, and parallel to the ground, the weight sustained by the wheel acts perpendicularly upon the road, and whatever shocks it may receive from resistances, fall upon its strongest position, where it is in no danger of giving way to the strain.

*The Position of Wheels.*—All wheels should revolve on perfectly straight axletrees, and be themselves perfectly parallel or perpendicular to the road. By this method there is the least stress in all given cases on the linch-pin, the axles, the spokes, and rim; and the friction less than in the conic wheels, which partly roll and partly drag.

*On the Line of Traction, and the Method by which Horses exert their Strength.*—In all four-footed animals, the hinder feet become the fulcrum of the lever by which their weight acts against the load; and when the animals pull hard, they depress their chest, and thus increase the lever of their weight, and diminish the lever by which the load resists their efforts; for it is a general law, that animals draw by their weight, and not by the force of their muscles. So that when a horse is employed in drawing, his effort will depend, in some measure, both upon his own weight and that which he carries on his back.

Indeed it is highly useful to load the back of a drawing horse to a certain extent; though this, on a slight consideration, might be thought to augment unnecessarily the fatigue of the animal: but it must be considered, that the mass with which the horse is charged vertically is added in part to the effort which he makes in the direction of traction, and thus dispenses with the necessity of his inclining so much forward as he must otherwise do; and may, therefore, under this point of view, relieve the draught more than to compensate for the additional fatigue occasioned by the vertical pressure. Carmen, and waggoners in general, are well aware of this, and are commonly very careful to dispose of the load in such a manner that the shafts shall throw a due proportion of the weight on the back of the shaft horse.

The best disposition of the traces during the time a horse is drawing, is to be perpendicular to the position of the collar upon his breast and shoulders: when the horse stands at ease, this position of the traces is rather inclined upwards from the direction of the road; but when he leans forward to draw the load, the traces should then become nearly parallel to the plane over which the carriage is to be drawn; or, if he be employed in drawing a sledge, or any thing without wheels, the inclination of the traces to the road, supposing it to be horizontal, should be about  $18\frac{1}{2}^{\circ}$ .

From the preceding observations, it will be easy in most cases to adapt the size of the wheels to that of the animal which is to draw in the shafts, so that when he leans forward to his work, the traces may be nearly parallel to the road, whether that road be horizontal or not; always recollecting, that, if there be any variation from the parallel position, it must be rather inclining upwards than downwards; as the former will somewhat diminish the friction, while the latter, instead of raising the wheels from any hollow into which they may fall, will tend to draw them down lower, and much increase the labour of the animal.

When several horses are harnessed one before another, so that they may all draw at the same load, and the slope on which they are drawing changes, as from DA to AB, (see the engraving in the next page,) the effort of the horse which draws along the road AB is decomposed into two parts, of which one tends to pull up the load, the other to pull down the horse which is in the shafts and is drawing along the slope DA. This latter component is always greater as the traces of the foremost horse are the longer. From the point E where the traces are fastened to the horse next the load, draw ER to the same point in the second horse R, and let R' be another position of the second horse; it is required to find the difference of effect that will be produced by placing the second horse at R or at R', or the comparative advantages of short and long traces. From R', the point where the traces are fixed, draw R'F'E; and from E draw Emn parallel to the declivity DA. Take EF = EF' to represent the power of the horse in the direction of the traces, which will be the same whether he is yoked at R or at R'; draw EA perpendicular to DA, Fn, F'm parallel to EA, and Fφ, F'φ parallel to En. Then, since the second horse when at R pulls with a force represented by FE, in the direction FE, we may resolve this force into the two forces En, Eφ, one of which En is solely employed in dragging the cart up the inclined plane DA, while the other Eφ is solely

employed in pressing the first horse *E* to the ground. Let the horse be now removed from *R* to *R'*, the direction of the traces becomes *R'E*, and *F'E* = *FE* is the power exerted by the horse at *R'*, and the direction in which it is exerted. But this force is equivalent to the forces *Em*, *Ef*, the first of which

acts directly against the load, while the other presses the horse against the ground. Hence we see the disadvantages of long traces, for the force which draws the load when the horse is at *R*' is to the force when the horse is at *R*, as *Em* to *En*, and the forces which press the horse upon the ground as *Ef* to *Eφ*, ...

... or as *F'm* to *F'n*. Now  $Eφ = Fn = FE \times \sin. nEF$ ; hence  $Fφ = FE \times \sin. (nEg' - FEg')$  (*g'E* being parallel to *AB'*) and  $En = EF \times \cos. (nEg' - FEg')$ . In like manner we have  $Ef = FE \times \sin. (nEg' - F'Eg')$ , and  $Em = EF \times \cos. (nEg' - F'Eg')$ . Now  $\sin. FEg' = \sin. FEg = \frac{Rg}{ER}$ ,

and  $\sin. FEg' = \frac{R'g'}{ER'} = \frac{Rg}{ER}$ ; but  $Rg = R'g' = BR - EQ = BR - BR \times \cos. nEg' = BR \times (1 - \cos. nEg')$ . By substituting this value in the equations which contain the values of *Eφ*, *En*, *Ef*, *Em*, and considering that the angles *FEg'*, *F'Eg'*, are always so small that their arcs differ very little from their sines, we have

$$FEg = \frac{BR \times 1 - \cos. nEg}{ER}, \text{ and } F'Eg' = \frac{BR \times 1 - \cos. nEg}{ER'}$$

By substituting these values in the preceding equations, we have

$$Eφ = EF \times \sin. (nEg - \frac{BR \times 1 - \cos. nEg}{ER}),$$

$$Efn = EF \times \sin. (nEg - \frac{BR \times 1 - \cos. nEg}{ER'}),$$

$$En = EF \times \cos. (nEg - \frac{BR \times 1 - \cos. nEg}{ER}),$$

$$Em = EF \times \cos. (nEg - \frac{BR \times 1 - \cos. nEg}{ER'}).$$

Suppose *AB* horizontal, the ascent *DCA*, that for every 6 feet, as *CN* in a horizontal plane, the vertical rise *NA* should be one foot; this slope is too steep for any common road, but may sometimes be met with in ascents from stone quarries, gravel pits, &c. In this case, the angle *nEg* will be nearly  $9^\circ 28'$ , which, expressed in decimal parts of the radius, gives  $\sin. 0.16522$ , and  $\cos. nEg = 0.98638$ . Then if *EF* = 200 lbs. *BR* =  $3\frac{1}{2}$  feet, *ER* = 8 feet, *ER'* = 12 feet. Then shall we have,

$$(1) \dots Fq = 200 \sin. (0.16522 - \frac{3.5(1 - 0.98638)}{8})$$

$$= 200 \sin. 9^\circ 7' 29'' = 31.716 \text{ lbs.}$$

$$(2) \dots F'q' = 200 \sin. (0.16522 - \frac{3.5(1 - 0.98638)}{12})$$

$$= 200 \sin. 9^\circ 14' 29'' = 32.25 \text{ lbs.}$$

$$(3) \dots Eq = 200 \cos. 9^\circ 7' 29'' = 177.47 \text{ lbs.}$$

$$(4) \dots E q = 200 \cos. 9^\circ 14' 29'' = 197.404 \text{ lbs.}$$

Hence it appears, that the horse whose breast is at *E* is pulled downwards by the other horse, with a force equivalent to about 32 lbs.: this weight is small for a horse that is not fatigued; but we should consider, that when drawing up a steep road the animal's strength is much weakened, so that it

may be obliged to yield to a very small effort. A lengthening of four feet to a trace of eight feet, will produce an augmentation of  $32.25 - 31.716 = 0.534$  lbs. in the effort which tends to pull the shaft horse down, and a diminution of  $197.47 - 197.404 = 0.066$  lbs. in the effort which raises the load up the hill. These quantities are not considerable; but it appeared desirable to explain the method of ascertaining their magnitude. And it may be added, that when a horse pulls for only a short time, as a few minutes, he will often exert a force equivalent to 500 or 600 lbs.: in which case, the tendency to pull down a shaft horse rising a hill would be thrice as much as we have stated it above; a force against which no horse could stand in such a disadvantageous position.

*On the Position of the Centre of Gravity, and the manner of disposing the Load.*—If the axletree of a two-wheeled carriage pass through the centre of gravity of the load, the carriage will be in equilibrio in every position in which it can be placed with respect to the axletree; and in going up and down hill the whole load will be sustained by the wheels, and will have no tendency either to press the horse to the ground, or to raise him from it. But if the centre of gravity is above the axletree, as it must necessarily be, according to the present construction of wheel-carriages, a great part of the load will be thrown on the back of the horses from the wheels when going down a steep road, and thus tend to accelerate the motion of the carriage which the animal is striving to prevent; while, in ascending steep roads, a part of the load will be thrown behind the wheels, and tend to raise the horse from the ground, when there is the greatest necessity for some weight on his back to enable him to fix his feet in the earth, and overcome the great resistance which is occasioned by the steepness of the road. On the contrary, if the centre of gravity is below the axle, the horse will be pressed to the ground in going up hill, and lifted from it when going down. In all these cases, therefore, where the centre of gravity is either on the axletree, or directly above it or below, the horse will bear no part of the load on level ground: in some instances he will be lifted from the ground, when there is the greatest necessity for his being pressed to it, and he will sometimes bear a great proportion of the load, when he should rather be relieved from it. The only way of remedying these evils, is, to assign such a position in the centre of gravity, that the horse may bear some portion of the weight when he must exert great force against the load, that is, in level ground, and when he is ascending steep roads; for no animal can pull with its greatest effort, unless it is enabled to use its feet as levers upon the ground as a prop or fulcrum. This may be effected in the following manner:—Let *CDE* (last figure but two) be the wheel of a cart, *AH* one of the shafts, *H* that part of the shaft by which the cart is suspended over the horse's back, *A* the axletree; then if the cart and the load together weigh 400 lbs., if the distance *AH* be 8 feet, and if the horse should bear 50 lbs of the weight, then *bA* should be one foot, which being one-eighth of *AH*, will make the pressure

upon H exactly 50 lbs, for  $50 \times 8 = 400$ , the whole load. If the road slopes 4 inches in a foot,  $bQ$  must be 4 inches, or the angle  $bAQ$  should be equal to the inclination of the road; for then the point Q will rise to  $am$  when ascending such a road, and will press with its greatest force on R the back of the horse. In a word, the centre of gravity Q is placed in a point equidistant from the two wheels, but before the line of traction AH, and before the axletree—the horse will bear a certain weight on level ground, a greater when going up hill, and has more occasion for it, and less weight, when going down hill, and does not require to be pressed to the ground. When carts are not made in this manner, we may, in some measure, obtain the same result by judiciously loading them. In a cart loaded with homogeneous materials, as sand, lime, &c. let us suppose the centre of gravity is at O, we should, with another load of heterogeneous materials, or bodies of different weights, place the heaviest at the bottom and nearest the front, which would lower the point  $a$ ; bring it further forward, and nearer its proper position Q, where part of the load suspended before the centre of gravity would still come nearer Q; but then the poor horse is very injudiciously burdened.

*Description of different Carriages that move without Horses.—*

In the annexed figure is represented a carriage invented by Mr. Richard, a physician in Rochelle, which moves without horses, merely by the exertion of the passengers. The machinery by which this is effected, is placed in a box behind the carriage, and is shewn in the 2d figure, where AA is a small axis fixed in the box, and B a pulley, over which a rope passes, whose two extremities are tied to the ends of the levers or

treddles C, D; the other ends of the levers are fixed by joints to the cross beam. The cranks FF are fixed to the axle KL, and move upon it as a centre. Each of them has a detent tooth at F, which catches in the teeth of the wheels H, H, so that they can move from F to H without moving the wheel, but the detent tooth catches in the teeth of the wheels when the cranks are brought backward, and therefore bring the wheel along with them. When the foot of the passenger, therefore, is placed upon the treddle D, it brings down the crank F and along with it the wheel H, so that the large wheels fixed on the same axis perform part of a revolution; but when D is depressed, the rope DA descends, the extremity C of the other treddle rises, and the crank F rising along with it, takes into the teeth of the wheel H, so that when the elevated treddle C is depressed, the wheels H, H, and consequently the wheels I, I, perform another part of a revolution. In this way, by continuing to work at the treddles, the machine advances with a regular pace.

A carriage of this kind, where the mechanism is much more simple and beautiful than that which we have described, has

been lately invented and constructed by Mr. Nasmyth, of Edinburgh, a gentleman whose mechanical genius is scarcely inferior to his talents as a painter. The pulley B and axle AA, are rendered unnecessary; leather straps are substituted in place of the cranks F, F, and the whole mechanism is contained in two small cylindrical boxes, about six inches in diameter, and one and a half broad.

A carriage driven by the action of the wind is exhibited in the annexed figure. It is fixed on four wheels, and moved by

the impulse of the wind upon the sails C, D, being guided by the rudder E. Carriages of this kind will answer very well in a level country where the roads are good and the wind fair; and are said to be used in China. In Holland they sometimes use similar vehicles for travelling upon the ice; but they have a

sledge instead of wheels, so that if the ice should happen to break, there will be no danger of sinking. Stepinus, a Dutchman, is said to have constructed one of these carriages with wheels, which travelled at the rate of 21 miles an hour with a very strong wind.

Dr. Phebus, of New York, has caused a wheel to be constructed which is put in motion by the wind. The plan of it is very simple. It has eight horizontal spokes attached to a perpendicular axle. Every one of the spokes is furnished with a sail which extends or contracts at pleasure, something like the sails of a vessel. Every sail is hooked up, from the right to the left, to the first loop of that which follows; and they are sufficiently large to receive the full impulse given by the wind. This machine, which is more easy to conceive than to describe, is very ingenious, and may be employed in a great number of manufactures.

The carriage represented in the annexed figure, is made so as to sail against the wind by means of the spiral sails E, F, G, H, one of which, F, is expanded by the wind. The impulse

of the wind upon the sails gives a rotatory motion to the axle M, furnished with a cog-wheel K, whose trundles act upon teeth placed on the inside of the two fore wheels.

A carriage which cannot be overturned, is represented in the next figure, where AB is the body of the carriage, consisting of a hollow globe, made of leather or wood, at the bottom of which is placed an immoveable weight. Two horizontal circles of iron, D, E, connected with bars H, I, and two vertical circles F, G, surround the globe; and the wheels are

fastened by a handle K to the perpendicular bars H, I, O, P, are handles or shafts by which to move the machine along. N is one wheel, and on the opposite side is another. O is a window. The door may be next to O P. Then, since the body of the carriage moves freely in every direction within the iron circles, the centre of gravity will always be near C, and the carriage will preserve an upright position even if the wheels and frame were overturned.

*Stage Coaches and Waggon.*—The danger of a stage coach overturning, arises either from two wheels on one side being driven into a hole, a ditch, or over a high bank, or running quickly to the side of a road very much rounded from its crown; or from turning a sharp corner with great velocity.

The *breaking down* of any coach is a disastrous and fatal accident, which will happen in future, as it has happened heretofore; and can only be prevented by the use of two pairs of idle wheels placed within the wheels in use, which is much the same as if we were travelling in two separate carriages.

A coach may be overturned by the centre of gravity being placed too high. Holes, ditches, banks, rounded roads, corners, and unequally loading to displace the centre of gravity, are all to be avoided by care, skill, and prudence; and in general by having the wheels perpendicular to the road, *i. e.* to the horizon, for the broader the base, and the nearer the line of direction is to the centre, the more firmly does the coach roll along; on the contrary, the narrower the base, *i. e.* the wheels, such as the conical, and the nearer the line of direction is to its side, the more easily may the coach be overthrown.

Suppose an overloaded waggon slopes on an uneven road, as shewn in the annexed figure, till the centre of gravity is at the point A; your eye will tell you that a vehicle thus situated, must overset; and the reason is, that the centre of gravity A, is not supported; for if you draw a perpendicular line from it to the ground at C, it does not fall under the waggon within the wheels, and is therefore not supported by them. If, however, we remove the centre of gravity to B, by taking off the upper part of the load, the waggon will not overturn, because the line of direction B D falls within the wheels at D.

The wheels of carriages turn round, on account of the friction they sustain in contact with the roads; and large wheels are more advantageous than small ones. In four-wheeled carriages, the fore wheels are made smaller than the hind ones, for the convenience of turning; otherwise they would be better of the same size. Broad wheels are better for heavy carriages—such as waggons—because they press and harden, instead of cutting up the roads, as small wheels do.

Much attention has of late been paid to the safety of passengers, by the construction of coaches in which the centre of gravity is brought very low, and the risk thereby greatly lessened. The legislature should pass an act to compel waggon-masters, van-proprietors, and coach-makers, to turn out such machines only as have their centres of gravity placed within the line of direction, when loaded at their utmost draught. It may be indifferent to draught, whether a ton be placed on the roof of a coach, or at its floor 2 feet from the ground; but it is material to danger and safety, that a ton weight be within 2, rather than 7 feet of the ground.

**CARTES, RENNES DES**, a celebrated French mathematician. Des Cartes explains mechanically how the world was formed, and how the present phenomena of nature came to arise. He supposes that God created matter of an indefinite extension, which he separated into small square portions or masses, full of angles: that he impressed two motions on this matter; the one, by which each part revolved about its own centre; and another, by which an assemblage, or system of them, turned round a common centre. From whence arose as many different vortices, or eddies, as there were different masses of matter, thus moving about common centres.

The consequence of these motions in each vortex, according to Des Cartes, is as follows:—The parts of matter could not thus move and revolve amongst one another, without having their angles gradually broken; and this continual friction of parts and angles must produce three elements; the first of these, an infinitely fine dust, formed of the angles broken off; the second, the spheres remaining after all the angular parts are thus removed; and those particles not yet rendered smooth and spherical, but still retaining some of their angles and hamous parts, from the third element.

Now the first or subtilest element, according to the laws of motion, must occupy the centre of each system, or vortex, by reason of the smallness of its parts: and this is the matter which constitutes the sun, and the fixed stars above, and the fire below. The second element, made up of spheres, forms the atmosphere, and all the matter between the earth and the fixed stars, in such sort, that the largest spheres are always next the circumference of the vortex, and the smallest next the centre. The third element, formed of the irregular particles, is the matter that composes the earth, and all terrestrial bodies, together with comets, spots in the sun, &c.

He accounts for the gravity of terrestrial bodies from the centrifugal force of the ether revolving round the earth; and upon the same general principles he pretends to explain the phenomena of the magnet, and to account for all the other operations in nature.

Des Cartes infers the existence of God from the principle, "*Cogito, ergo sum*;" "I think, therefore I am!" and thinks his inference just, because it satisfies his reason: he proceeds on a supposition, that what satisfies his reason is true; and takes it for granted, that his reason is not a fallacious but a true faculty; hence his argument proceeds on a supposition, that the point to be proved is true. He therefore attempts to prove the truth of our faculties by an argument which evidently and necessarily supposes their truth; and consequently his metaphysics is built on sophisms. As this philosopher doubted where he ought to have been confident, so he is often confident where he ought to doubt. He admits not his own existence till he thinks he has proved it; yet his system is replete with hypotheses, taken for granted without proof, almost without examination. He sets out with the profession of universal scepticism, while many of his theories are founded on the most unphilosophical credulity. Des Cartes erred materially when he concluded, that the most perfect kind of science was to be arrived at by inferring effects from their causes; for, consistently with this conclusion, he endeavoured, from his knowledge of the Deity, (which must necessarily be imperfect,) to deduce an explication of all his work, and thus produced a system almost in every respect repugnant to truth and experiment. Des Cartes was so far from applying geometry and observations to natural philosophy, that his whole system is one continued blunder, on account of his negligence in that point. His theory of vortices, upon which his system is founded, is absolutely false; for Newton has shewn, that the periodical times of all bodies that swim in vortices, must be directly as the *squares of their distances* from the centre of them; but it is evident, from observations, that the planets, in moving round the sun, observe a law quite different from this; for the squares of their periodical times are always as the *cubes of their distances*; and therefore, since they do not observe that law, which of necessity they must if they swim in a vortex, it is a demonstration that there are no vortices in which the planets are carried round the sun; and therefore Des Cartes' hypothesis is absurd, irrational, and not capable of mathematical proof.

The Cartesian system has been often altered and mended; many ingenious men, for full a century, employing their talents in reforming one part and new-modelling another. But it is now acknowledged on all hands, that the foundation was faulty, and the superstructure erroneous; so that the fabric, though allowed to be a work of genius, is abandoned to neglect and ruin, and is pointed at as a memorial of philosophical presumption. Yet this system, or one much more absurd, has been broached of late, by a person who denominates his vagaries, "the philosophy of Atomic motion." Des Cartes died in 1650.

**CARTWRIGHT**, a person who makes carts, ploughs, harrows, wheelbarrows, and in short all sorts of country and farming carpentry,—for the word *wright* signifies in the North, a *joiner*. But cartwrights are confounded with *wheelwrights*, though the latter only were recognized in old times as the legitimate makers of carriages, of what name soever these might be called.

**CASKS**, *The Manufacture of*, is now much facilitated by machinery, which was invented by Messrs. Plakete and Brown, in 1811, and is thus perspicuously described in Dr. Gregory's "Mechanics."

"First. The machinery for cutting the stave consists of a stout bench, having a board or platform annexed to it, capable of being moved endways, to which another board is connected, so arranged as to be moved across it steadily by racks and pinions, or screws. This last board has a hollow part made in it, in which the staveboard may be laid, so that one edge of it may project clear beyond the edge of the first mentioned board: a circular saw is placed either above or below the bench, having its axis at right angles to the line of motion of the first mentioned board, and opposed to the direction of the course of the projecting part of the staveboard: this circular saw is made flat, when the straight-edged staves are to be cut; and is dishd, or of a spherical shape, when staves with curved edges are wanted.

"The board first mentioned is moved either in a right line, or is made to assume a curved course by being confined in its motion by curved grooves, or by curved rods moving against pins; and by the proper management of these sliding boards, the staveboard is cut by the circular saw, of the shape desired.

"The machinery next used consists of a large lathe, in which the cask is turned in a vertical position when it is of a large size, (after it is formed in the usual manner from the staves prepared as above described,) being either fixed in a great chuck placed beneath it, or in a cylindrical cage, which surrounds it, fixed upon a strong upright arbor, and revolving between collars, where it serves the office of a mandril. In this lathe the chime and groove for receiving the head are turned in the cask by the application of a proper tool. When the cask is small, the cage is made to turn in a horizontal position, instead of revolving vertically.

"The third operation is to form the head, which is pinioned together as usual, after having the pinholes made by piercers, projecting from the mandril of a lathe; the distances and depth of which holes are correctly regulated by gauges; it is then turned on a flat revolving table, from which points project to hold it fast, and against which it is held by another revolving piece, that is screwed towards the first, where it is brought to the proper size of the cask by fit tools.

"The fourth operation is to turn the whole cask at the outside; for which purpose, it is placed in a large lathe between two chucks, made to fit into the chimes, and attached to the head by points; and then the surface of the cask is turned smooth by a spokeshave, or other fit instrument, held against it by a rest properly placed for the purpose.

"The patentees bend the wooden hoops for their casks in a more expeditious manner, by fastening one end of them to the circumference of a wheel, and pressing them against the wheel as it is turned round: they also describe a method of forming the projecting part in the bung staves of the small casks, called bottles, by flat or concave circular saws, which cut the face of the stave on each side close up to the projection; and lastly, in giving motion to this machinery, the inventors use any of the usual first movers, and millwork, as may be necessary."

**CASSINI, JOHN DOMINIC**, an eminent astronomer, born at a town in Piedmont, in 1625. In 1650 he was invited to the senate of Bologna to be their public mathematical professor, while he was yet but twenty-five years of age. He resolved an astronomical problem, which Kepler and Bullialdus had given up as insolvable, viz. to determine geometrically the apogee and eccentricity of a planet, from its true and mean place. In 1666 he printed at Rome a collection of astronomical pieces, and among others, a "Theory of Jupiter's Satellites." Cassini died in 1712, in the 87th year of his age.

**CASSINI, John James**, the son and successor of the above, born at Paris in 1677, and educated at the Mazarine College, under Varignon, Professor of Mathematics. At the age of seventeen he was admitted a member of the Academy of Sciences; and in 1696 he visited England, where he was chosen a Fellow of the Royal Society. He succeeded his father in 1712, and enriched the stock of science with many valuable discoveries. He died in consequence of a fall, in 1756.

**CASSIOPEIA**, one of the Northern Constellations, represented as the Wife of Cepheus, and Mother of Andromeda, but is called *El Seder*, the Cedar tree, by Ulug Beig.—The boundaries and contents are: north by Tarandus, east by Camelopardalis and Perseus, south by Andromeda, and west by Cepheus.—This constellation, situated between 45° and 75° north declination, passes vertically over the British isles, and a large portion of Europe. It lies between 47° and 55° right ascension. It contains 55 stars, viz. five of the 3d magnitude, five of the 4th, &c. The head and body of this lady are placed in the Milky Way, her right foot resting on the Arctic Circle. Relatively to the two Bears, Cassiopeia is placed opposite to the space between them, and she is very easily distinguished by five stars of the 3d magnitude. In the year 1752, Tycho Brahe discovered in this constellation, a new star which shone with more light than Venus, till 1574, when it disappeared entirely. *Schedir*,  $\alpha$ , having 7° 35' 7", or 0<sup>h</sup> 29' 40" right ascension, and 55° 32' 58" declination north, culminates or comes to the meridian at London, for the first day of every month during the year, as shewn in the following table: Meridian Altitude 85° 58' 2" north.

**CASTING and MOULDING**. The art of taking impressions from pieces of sculpture, medals, &c. is of importance in the fine arts. To procure a cast from any figure, bust, medal, &c. it is necessary to obtain a mould, by pressing upon the thing to be copied some substance capable of being forced into all the cavities or hollows of the sculpture. When this mould is dry and hard, some substance which will fill all the cavities of the mould is poured into it: the form of the original from which the mould was taken, is now accurately represented. Moulding in any particular manner depends upon the form of the subject. When there are no projecting parts but such as form rectilineal angles with the principal surface of the body, nothing more is necessary than to cover it over with the substance of which the mould is to be formed, and to take it off clean, and without bending. It may be laid horizontally, and will bear to be oiled without injury.

The substances used for moulding are various, according to the nature and the situation of the sculpture, as wax, metal, plaster of Paris, &c. This last is prepared in a fine powder mixed with water, and poured over the mould to a convenient thickness, after oiling it, to prevent the plaster from sticking. A composition of bees' wax, resin, and pitch, makes a very desirable mould, if many casts are to be taken. If the situation of the sculpture be perpendicular, clay, or some similar substance, must be used. The best kind of clay is that with which sculptors make their models; it is worked to a due consistence, and having spread it out to a size sufficient to cover all the surface, it is sprinkled over with whiting, to prevent it from adhering to the original. Bees' wax and dough, or the crumb of new bread, may also be used for moulding some small subjects, as impressions of seals and bijoux. When

there are undercuttings in the bas-relief, they must be first filled up before it can be moulded, otherwise the mould could not be got off. When the casts are taken afterwards, these places must be worked out with a proper tool. When the model, or original subject, is of a round form, or projects so much that it cannot be moulded in this manner, the mould must be divided into several parts; and it is frequently necessary to cast several parts separately, and afterwards to join them together.

In this case, the plaster must be tempered with water to such a consistence, that it may be worked like soft paste, and laid on with some convenient instrument, compressing it till it adapt itself to all parts of the surface. When the model is thus covered to a convenient thickness, the whole is left at rest till the plaster become firm, so as to bear dividing without falling to pieces by any slight violence; it must then be divided into pieces to be taken from the model. This is done by cutting it with a thin-bladed knife; being now divided, it must be cautiously taken off, and kept till dry; but, before the separation of the parts is made, they are notched across the joints, at proper distances, that they may with certainty be put together again. The art of properly dividing the moulds, to make them separate from the model, requires dexterity and skill. Where the subject is of a round or spheroidal form, it is best to divide the mould into three parts, which will then easily come off from the model; and the same will hold good of a cylinder, or any regular curve figure.

The mould being thus formed, and dry, and the parts put together, it must be first oiled, and placed in such a position that the hollow may lie upwards. It is then filled with plaster mixed with water; and when the cast is perfectly set and dry, it is taken out of the mould, and repaired where necessary. This finishes the operation. In larger masses, where there would otherwise be a great thickness of the plaster, a core may be put within the mould, as was observed in regard to the casting of statues, to produce a hollow in the cast. This saves expense of plaster, and renders the cast lighter.

In the same manner, figures, busts, &c. may be cast of lead, or any other metal, in the moulds of plaster or clay; the moulds must be perfectly dry, for should there be any moisture, the sudden heat of the metal will convert it into vapour, and produce by its expansion, an explosion, that would blow the melted metal about to the great danger of the artist.

*To take a Cast in Metal from any small Animal, Insect, or Vegetable.*—Prepare a box, sufficiently large to hold the animal, in which it must be suspended by a string: the legs, wings, &c. of the animal, or the tendrils, leaves, &c. of the vegetable, must be separated and adjusted in their right position by a pair of pincers. A due quantity of plaster of Paris mixed with talc, must be tempered to a proper consistence with water, and the sides of the box oiled. Also a straight piece of stick must be put to the principal part of the body, and pieces of wire to the extremities of the other parts, that they may form, when drawn out after the matter of the mould is set and firm, proper channels for pouring in the metal, and vents for the air, which otherwise, by the rarefaction it would undergo from the heat of the metals, would blow it out, or burst the mould. In a short time the plaster will set, and become hard; the stick and wires may now be drawn out, and the frame in which the mould was cast taken away; and the mould must then be put, first, into a moderate heat, and, afterwards, when it is as dry as it can be rendered by that degree, removed into a greater, which may be gradually increased, till the whole be red hot. The animal or vegetable enclosed in the mould will then be burnt to a coal; and may be totally calcined to ashes, by blowing for some time into the charcoal and passages made for pouring in the metal, and giving vent to the air. This operation, at the same time that it destroys the remainder of the animal or vegetable matter, will blow out the ashes. The mould is then allowed to cool gently; the destruction of the substance that had been included in it, has now produced a corresponding hollow; but it may nevertheless be proper to shake the mould, and blow with bellows into each of the air vents, to free it wholly from any remaining ashes; where there may be an opportunity of filling the hollow with quicksilver, it will be found an effectual method of cleaning the cavity, as all dust and ashes must rise to the surface of the quicksilver, and be poured out with it.

The mould being thus prepared, must be heated very hot, when used, if the cast is to be made of copper or brass, but a less degree will serve for lead or tins. The metal being poured into the mould, it must be gently struck, and then suffered to rest till it be cold; it is then carefully taken from the cast, but without force; such parts of the matter as appear to adhere more strongly, are to be softened, by soaking in water till they be entirely loosened, that none of the more delicate parts of the cast may be broken off or bent.

When talc cannot be obtained, plaster alone may be used; it is apt however to be calcined, by the heat used in turning the animal or vegetable from whence the cast is taken, and to become of too incoherent and fusible a texture. Stourbridge clay, washed perfectly fine, and mixed with an equal part of fine sand, may be employed. Pounded pumice-stone, and plaster of Paris, in equal quantities, mixed with washed clay in the same proportion, make excellent moulds.

*To take a Cast in Plaster from a Person's Face.*—The person whose likeness is required in plaster, lays down on his back, the hair is tied back, so that none of it may cover the face. Into each nostril a conical piece of stiff paper open at both ends is conveyed, to allow of breathing. The face is then lightly oiled over with salad-oil, to prevent the plaster from sticking to the skin. Fresh burnt plaster is mixed with water to a proper consistence, and poured in spoonfuls all over the face, (taking care the eyes are shut,) till it is entirely covered to the thickness of a quarter of an inch. This substance will grow sensibly hot, but this the patient must not fear; for in a few minutes the plaster will be hard. This being taken off, will form a mould, in which a head of clay may be moulded, and therein the eyes may be opened, and such other additions and corrections may be made as are necessary. Then, this second face being anointed in oil, a second mould of plaster is made upon it, consisting of two parts joined lengthwise along the ridge of the nose; and in this a cast in plaster is taken, as an exact likeness of the original.

*To take Casts from Medals.*—To take copies of medals, a mould must first be made, of plaster of Paris, or of melted sulphur. After having oiled the surface of the medal with a little cotton, or a camel's hair pencil dipped in oil of olives, a hoop of paper must be put round the medal, standing up above the surface, of the thickness you wish the mould to be. Take now some plaster of Paris, mix it with water to the consistence of cream, and with a brush rub it over the surface of the medal, to prevent airholes from appearing; then immediately afterwards make it to a sufficient thickness, by pouring on more plaster. Let it stand half an hour, when it will have grown so hard, that you may safely take it off; then pare it smooth on the back, and round the edges neatly. In cold or damp weather it should be dried before a brisk fire. When the mould is large, if you cover its face with fine plaster, a coarser sort will do for the back: but no more plaster should be mixed up at one time than can be used, as it will soon get hard, and cannot be softened without being burned over again. Sulphur must not be poured upon silver medals, as this will tarnish them.

To prepare your mould for casting sulphur, put plaster of Paris into it, take half a pint of boiled linseed oil, and one ounce of oil of turpentine, and mix them together in a bottle; dip the surface of the mould into this mixture; take the mould out again, and when it has sucked in the oil, dip it again. Repeat this till the oil begins to stagnate upon it; then take a little cotton wool, hard rolled up, to prevent the oil from sticking to it, and wipe it carefully off. Lay it in a dry place for a day or two, (if longer the better,) and the mould will acquire a very hard surface from the effect of the oil. To cast plaster of Paris in this mould, proceed with it in the same manner as above directed for obtaining the mould itself, first oiling the mould with olive oil. When casts are wanted of sulphur, the material must be melted in an iron ladle.

*To take Casts with Isinglass.*—Dissolve isinglass in water over the fire. With a hair brush lay the wetted isinglass over the medal. Cover it properly, and let it dry. When hard, raise the isinglass with the point of a knife, and it will fly off like horn, leaving a sharp impression of the medal. You may make the isinglass of any colour, by mixing that colour with it when in a state of solution; or you may breathe on the concave

side, and lay gold leaf on it, which, by shining through, will make it appear like a gold medal. A little carmine mixed with the isinglass will give it the appearance of a copper medal, observing to lay the gold on the concave side.

*To cast Small Works in Sand.*—The sand is usually a soft yellowish clammy substance; but as we see it in an iron foundery, it is black, from the charcoal which the workmen strew over it. This sand, after being placed over a trough to receive it, is worked on a board, with a roller and a knife. The workmen then take a board, putting a ledge round, and fill it with sand, a little moistened, to make it cohere. Then the wood or metal models of what is intended to be cast, are applied to the mould, and pressed into the sand, to leave the impression. Along the middle of the mould, half of a small brass cylinder is laid; the metal runs through this chasm into the models; from this are placed several others, to each model placed in the frame. After the frame is finished, the workmen then take out the patterns, by loosening them all round, that the sand may not give way. They then work the other half of the mould with the same patterns, in another frame. In this last frame are pins, which, entering into correspondent holes in the other, make the two cavities of the pattern fall exactly on each other. The frame thus moulded, is carried to the melter. He extends the

chief canal of the counterpart, adds the cross canals to the several models in both, and strewing mill-dust over them, dries them in an oven. Both parts of the mould being dry, are joined by the pins, and screwed up like a press. While the moulds are preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

*To cast Cannon.*—The casting cannons, mortars, and other pieces of ordnance, is like that of statues and bells, especially as it regards the mould, wax, shell, furnaces, &c. The metal is different, however, having a mixture of tin, which is not in that of statues; and only half the quantity of tin that is in bells, at the rate of ten pounds weight of tin to a hundred of copper. Cannons are always thickest at the breach, where the greatest effort of the gunpowder is made, and diminishing thence to the muzzle; so that if the mouth be two inches thick of metal, the breech is six. Its length is measured in calibers, or diameters of the muzzle. Six inches at the muzzle require twenty calibers, or ten feet in length; there is about one-sixth of an inch allowed for the deviation of the ball, and in this manner are all our guns estimated.

CASTLE, a Fortress, or building rendered defensible either by nature or art. In the following engraving, A is the *barbican*; B the *ditch*, or moat; C the *wall* of the outer ballium;

or the outer ballium; E the artificial mount; F the wall of the inner ballium; G the keep, or dungeon. All the towers, magazines, &c. speak for themselves. Between the outer ballium and the barbican, and directly over the moat or ditch, the drawbridge is constructed, opening or rising to the ballium gate, and leaving the way impassable to those who may try to force and enter the barbican.

CASTOR and POLLUX, the allegorical figures in the sign Gemini, which give name to the two principal stars in that constellation.

CAT, in sea affairs, a ship of 600 tons or thereabouts, carrying from 20 to 30 keels (or barges) of coals. CAT is also a tackle, or combination of pulleys, to suspend the anchor at the cat's-head.

CATACOMB, a Grotto, or subterranean place for the burial of the dead, as the sepulchre of the martyrs in the Appian Way, about three miles from Rome; the catacombs of Naples, Syracuse, Catanea, Malta, Paris; but above all, those in Egypt are the most celebrated.

CATALOGUE, a list or enumeration of books, or of the stars, or of the Popes, as the Jesuit's *Propilæum*.

CATAPULTA, in Antiquity, a military engine for throwing stones or darts upon an enemy; but modern warfare dispenses with those awkward machines, and so shall we.

CATARRH, in Medicine, a distillation or defluxion from the head upon the mouth and *aspera arteria*, and through them upon the lungs.

CATENARY, CATENARIA, in the higher Geometry, a mecha-

nical curve, which a chain or rope forms itself into by its own weight, when hung freely between two points of suspension, whether those points be in the same horizontal plane or not. See CHAIN BRIDGE.

CATGUT, fiddle strings, made of the dried and twisted guts of sheep, lambs, dogs, and cats. The Lyons and Italians are the great manufacturers of catgut for our musicians, watch-makers, cutlers, turners, and other artificers.

CAT-HEADS, two strong short beams of timber, projecting almost horizontally over the ship's bows on each side of the bowsprit. That part of the cat-head which rests upon the fore-castle is securely bolted to the beams; the other projecting part carries in its extremity two or three small wheels, or sheaves of brass or strong wood, about which a rope called the cat-dole passes, and communicates with the cat-block, which also contains three sheaves. The cat-head also serves to suspend the anchor clear of the bow, when it is necessary to let it go: it is supported by a sort of knee, which is generally ornamented with sculpture.

CATOPTRICS, the science of reflex vision, which is treated of under the article MIRROR.

CATSALT, formed out of the bittern, or leach brine, that runs from the salt when taken from the pans at the salt works, is very beautifully granulated, sharp and pungent, and much more pleasant at the table than the fine but white powdered salt in common use. Fashion, not taste, must have consigned the large beautiful crystals of catsalt to the makers of hard soap and fish curers.

**CAT'S-EYE**, or **SUN STONE**, a gem whose colours vary like the *opal*, very hard, semitransparent; and which, from the several points it may have naturally, or into which lapidaries can fashion it, reflects the light with a kind of yellowish radiation, something similar to the eyes of a cat, whence the name of this Siberian onyx.

**CAUSTIC**, or **CATACAUSTIC CURVES**, in the higher Geometry and Optics, are the species of curves formed by reflection, or by joining the points of concurrence of several reflected rays. The caustic of the circle is a cycloid, or epicycloid, formed by the revolution of a circle upon a circle. The catacaustic of the common cycloid, when the rays are parallel to its axis, is also a common cycloid, described by the revolution of a circle upon the same base. That of a logarithmic spiral is also the same curve. If the inside of a smooth bason, containing in it any white liquor, as milk, be placed in the sun's rays, or in a strong candlelight, it will exhibit a very perfect catacaustic curve.

**CAWKING** or **CAULKING** a ship, is driving a quantity of oakum, or untwisted rope, into the seams of the bottoms and decks of ships, in order to prevent the entrance of water; and *caulking irons* are chisels for that purpose, being some broad, some round, and some grooved.

**CELA SCULPTORIS**, or **PRAXITELES**, the *Engraver's Tools*, is a small modern constellation, bounded on the north by *Lepus*, east by *Columbia*, south by *Equuleus Pictorius*; and west by *Horologium* and *Eridanus*. There are sixteen stars assigned to this asterism, in the *Britannic Catalogue*.

**CELESTIAL**, relating to the heavens; hence we say *Celestial Globe*, *Celestial Atlas*, &c.

**CELLAR CRANE**, a machine represented in the following figure, and is very useful to wine-merchants, brewers, &c. in drawing up and letting down casks full of wine, beer, &c. It saves the trouble and inconvenience of horses, and in many places can be used where horses could not. A, A are two wooden props, about 6 feet in height, and jointed together like a ruler at B. They are connected to each other by an iron round bar C, and wooden bar at the bottom, D. The iron prongs E E fasten the uprights steadily to the edge of the cellar; F is the axis round which two ropes are coiled, the ends of which are fastened to the two clamps G, G. On the axis F is fixed the iron wheel H of 3 feet in diameter: in the teeth of this works

the pinion I, of about 6 or 7 inches in diameter, and is turned by the handle at K. It is evident, by the figure, that when the two ropes are slipt over the ends upon the barrel, either at the top or bottom of the cellar, by turning of the winch K towards or from the operator, the barrel can be safely and expeditiously taken out or lowered down. When the crane is done with, it shuts up, by unscrewing the nut B, taking the wheel and axis away out of the loops at L, and folding the sides at A together, like a jointed rule; it may then be taken away in the cart or dray, or taken in the men's hands.

**CEMENT**, in general, is any glutinous substance capable of uniting and keeping things together in close cohesion. Cements are of various compositions, according to the substances to which they are applied, and their exposure to heat and moisture.

**Common Glue**.—Common glue is formed by extracting the gelatinous part of cuttings or scraps of coarse leather, or the hides of beasts: it is never manufactured but in a large way.

**Isinglass Glue**.—Isinglass glue is made by dissolving beaten isinglass in water by boiling; having strained it through a coarse linen cloth, it evaporates again to such a consistence,

that, being cold, the glue will be hard and dry. This cement is improved by dissolving the isinglass in proof spirit by heat, or by adding to it, when dissolved in water, an equal quantity of spirits of wine. It is still further improved, by adding to the isinglass, previous to its solution in spirits, one-third of its weight of gum ammoniac. Expose the mixture to a boiling heat until the isinglass and gum are dissolved, and until a drop of the composition becomes instantly stiff as it cools. It will in future melt with a degree of heat little exceeding that of the human body, and, in consequence of becoming stiff in cooling, forms a valuable cement for fixing on the antennæ, &c. of insects in the cabinet of natural history. The easy melting of this cement is no objection to its use, for it owes this property only to the presence of the spirit, which evaporates soon after it has been applied. When used to join broken glass or china, the pieces should be previously warmed, and immersion in hot water will give them a sufficient degree of heat. Wipe off the water before applying the cement, which may be laid on with a pencil; then press the pieces together, binding them with a string or a bit of soft wire, if necessary. For nice purposes, this isinglass glue is preferable to common glue, being stronger, and less liable to soften by heat or moisture.

**Parchment Glue** is made of one pound of shreds of parchment or vellum, boiled in six quarts of water, till the quantity be reduced to one quart; the fluid is strained off from the dregs, and then boiled again till it be of the consistence of glue. Glovers' cuttings of leather dressed with alum, instead of being tanned, makes a colourless glue.

**To make Signboard Glue**.—Melt common glue with water to a proper consistence; add one-eighth of boiled linseed oil, dropping it gently into the glue, which is to be kept stirring all the time. A strong glue is made by adding some powdered chalk to common glue, and another that will resist water by adding half a pound of common glue to two quarts of skimmed milk.

**To prepare Lip Glue for Cementing Paper**, &c.—Take of isinglass and parchment glue, each one ounce; of sugarcandy, and gum tragacanth, each two drachms; add to them an ounce of water, boil the whole, till the mixture appears, when cold, of the consistence of glue. Then form it into small rolls for use. This glue wetted with the tongue, and rubbed on the edges of the paper, silk, &c. to be cemented, will, on their being laid together, and suffered to dry, unite them as firmly as any other part of the surface.

**Lapland Glue**.—Laplanders' bows are composed of two pieces of wood glued together; one of them of birch, which is flexible, and the other of fir of the marshes, which is stiff, in order that the bow when bent may not break, and that when unbent it may not bend. When these two pieces of wood are bent, all the points of contact endeavour to disunite themselves, and to prevent that, the Laplanders employ the following cement:—They take the skins of large perches, and having dried them, moisten them in cold water until they are so soft that they may be freed from the scales, which are thrown away; probably eel skins would answer the same purpose. They then put four or five of these skins into a reindeer's bladder, or they wrap them up in a soft bark of the birch tree, in such a manner that water cannot touch them, and place them thus covered into a pot of boiling water, with a stone above them to keep them at the bottom. When they have boiled about an hour, they take them from the bladder or bark, and they are then found to be soft and viscous. In this state they employ them for glueing together the two pieces of wood which compose their bows, and which they strongly compress and tie up till the glue is well dried. These pieces never after separate.

**Cheese Glue**.—Take skimmed milk cheese, freed from the rind, cut it into slices, boil it in water, stirring it with a spoon until it be reduced to a strong glue, which does not incorporate with water; then throw away the hot water; pour cold water over the glue, and knead it afterwards in warm water, subjecting it to the same process several times. Put the warm glue on a grinding stone, and knead it with quicklime until you have a good glue. To use this glue you must warm it; employed cold, it is not so strong, but it may be used in that manner. This glue is insoluble in water as soon as it is dry, and it becomes so in forty-eight hours after it has been applied.

It may be used for glueing wood, cementing marble, and broken earthenware. Baits for catching fish may also be made of it. Fish are very fond of it, and it resists water.

**Jewellers' Cement.**—In setting precious stones, pieces are sometimes broken off by accident, but these may be joined so correctly, that an inexperienced eye would not discover the stone to have been broken. Jewellers employ for this purpose a small piece of gum mastich applied between the fragments, which are previously heated sufficiently to enable them to melt the interposed gum. They are then pressed together, to force out the redundant gum.

**Turkey Cement for joining Metals, Glass, &c.**—Dissolve six bits of mastich, as large as peas, in as much spirits of wine as will suffice to liquefy; in another vessel dissolve as much isinglass (which has been previously soaked in water till it has swollen and is soft) in brandy or rum, as will make two ounces by measure of strong glue, and add two small bits of gum galbanum, or ammoniacum, which must be rubbed till they are dissolved; then mix the whole with a sufficient heat; keep it in a phial stopped, and when used set it in hot water.

**Broken China Cement.**—Take quicklime and white of eggs, or old thick varnish; grind and temper them well, and it will be ready for use. Drying oil and white lead are used for cementing china and earthenware; but this cement requires a long time to dry. Where the vessels are not to endure heat or moisture, isinglass glue, with a little tripoli or chalk, is better; the juice of garlic also forms a strong cement, and the joining cannot easily be perceived.

**Chemical-Glasses' Cement.**—In the whites of eggs mix equal quantities of wheat flour, fine powdered Venice glass, pulverized chaff, with half the quantity of fine brick dust, and a little scraped lint. This mixture is spread upon a linen cloth, and applied to the crack of the glasses; it should be dried before they are put to the fire.

**Turner's Cement.**—Melt together resin one pound, pitch four ounces; and, while boiling hot, add brick dust, until, by dropping a little upon a stone, you perceive it hard enough; then pour it into water, and immediately make it up in rolls, and it is fit for use.

Another, finer. Take resin one ounce, pitch two ounces; add red ochre, finely powdered, until you perceive it strong enough. Sometimes a small quantity of tallow is used, according to the heat of the weather, more being necessary in winter than summer. Either of these cements is of excellent use for turners. By applying it to the side of a chuck, and making it warm before the fire, you may fasten any thin piece of wood, which will hold fast while you turn it; when you want it off again, strike it on the top with your tool, and it will drop off immediately.

**Electrical Cement.**—Melt in a pot, over a slow fire, one pound of resin; add as much plaster of Paris, in fine powder, as will make it hard enough, which you may know by trial; then add a spoonful of linseed oil, stirring it all the while, and try if it be hard and tough enough for your purpose; if it is not sufficiently hard, add more plaster of Paris; and if not tough enough, a little more linseed oil. This is for fixing the necks of globes or cylinders, or any thing that requires to be strongly cemented, for it is not easily melted when cold.

Another, softer. Take resin one pound, bees' wax one ounce; add as much red ochre as will make it sufficiently stiff; pour it into water, and make it into rolls for use. This cement is for cementing hoops on glasses, or any other mounting of electrical apparatus.

**Glass Grinders' Cement.**—Boil pitch, adding thereto fine sifted wood ashes, until you have it of a proper temper, stirring it all the while; a little tallow may be added, as you find necessary.

Another, for small work. To four ounces of resin add one-fourth of an ounce of bees' wax, melt them together, adding four ounces of whitening made previously red hot. The whitening should be put while hot, that it may not have time to imbibe moisture from the atmosphere. Shell lac is a strong cement for metals, glass, or precious stones, while cutting, twining, or grinding them. The metal, &c. should be warm to melt it. Shell lac is excellent for fastening ruby cylinders in watches, and similar delicate purposes.

**Broken Glass Solder.**—Broken glass is soldered by interposing between the parts, glass ground up like a pigment, but of easier fusion than the pieces to be joined, and then exposing them to such a heat as will fuse the cementing ingredient, and make the pieces agglutinate without being themselves fused.

A glass for cementing broken pieces of flint glass may be made by fusing some of the same kind of glass previously reduced to powder, with a little lead and borax, or with borax only.

**Derbyshire Spar Cement, &c.**—This cement is made with about eight parts of resin and one of bees' wax, melted together with a small quantity of plaster of Paris. If the cement is to fill up the place of any small chips that may have been lost, the quantity of plaster may be increased a little. When the ingredients are well mixed, and the whole nearly cold, the mass must be well kneaded together. The pieces of spar to be joined, must be heated until they melt the cement, and then pressed together, some of the cement being previously interposed. Melted sulphur applied to fragments of stones previously heated (by placing them before a fire) to at least the melting point of sulphur, and then joined with the sulphur between, makes a pretty firm and durable joining. Little deficiencies in the stone, as chips out of corners, &c. may also be filled up with melted sulphur, in which some of the powder of the stone has been melted.

**Steam Cement.**—To join the flanches of iron cylinders, and other parts of hydraulic and steam engines, the following methods are adopted by machinists:—Boiled linseed oil, litharge, red and white lead mixed together to a proper consistence, applied on each side of a piece of flannel, previously shaped to fit the joint, and then interposed between the pieces before they are brought home, (as the workmen term it) to their place by the screws or other fastenings employed, make a close and durable joint. The quantities of the ingredients may be varied without inconvenience, taking care not to make the mass too thin with oil. It is difficult in many cases instantly to make a good fitting of large pieces of iron work. This renders it necessary sometimes to join and separate the pieces repeatedly before a proper adjustment is obtained. When this is expected, the white lead ought to predominate in the mixture, as it dries much slower than the red. A workman knowing this fact, can be at little loss in exercising his own discretion in regulating the quantities. It is safest to err on the side of the white lead, as the durability of the cement is not thereby effected, a longer time only is required for it to dry and harden. When the fittings will not easily admit of so thick a substance as flannel being interposed, linen may be substituted, or even paper or thin pasteboard. This cement answers well also for joining broken stones, however large. Cisterns built of square stones, put together with this cement, will never leak, or want any repairs. In this case, the stones need not be entirely bedded in it; an inch, or even less, of the edges that are to be next the water, need only be so treated; the rest of the joint may be filled with good lime.

Another of the same. This cement, preferable even to the former, for steam-engines, is prepared thus:—Take two ounces of sal ammoniac, one ounce of flowers of sulphur, and sixteen ounces of cast iron filings or borings; mix them in a mortar, and keep the powder dry. When the cement is wanted for use, take one part of the above powder, and twenty parts of clean iron borings or filings; and blend them intimately by grinding them in a mortar. Wet the compound with water, and when brought to a convenient consistence, apply it to the joints with a wooden or blunt iron spatula. This is the cement with which the joinings of the Southwark cast-iron bridge were filled up and clasped. Action and reaction take place among the ingredients, and between them and the iron surfaces, which at last causes the whole to unite as one mass. After a time, the surfaces and the mixture become one.

**Roman Cement.**—By a recent analysis of Parker's Roman cement, by Monsieur Berthier, he finds that its constituents differ so little from the constituents of chalk and common clay, that he proposes the manufacturing of a similar cement by the mere mixture of them in certain proportions—One part of clay, and two and a half parts of chalk, sets almost instantly, and may therefore be regarded as Roman cement.

**Blood Cements**, are used by coppersmiths to lay over the rivets and edges of the sheets of copper in boilers of the first class: they also give additional security to the joinings, and secure cocks from leaking. This cement is made by mixing pounded quicklime with oxen's blood: but unless used when fresh made, it will become hard. It is durable, cheap, and extensively applicable in the rougher branches of art.

**Flour Paste Cement.**—Flour paste for cementing, is formed principally of wheaten flour, boiled in water till it be of a glutinous or viscid consistence. It may be prepared of these ingredients simply for common purposes, but when it is used by bookbinders, or for paper hanging, it is usual to mix with the flour a fifth or sixth of its weight of powdered alum; and where it is wanted still more tenacious, gum arabic, or any kind of size, may be added.

**Rice Glue.**—This elegant cement is made by mixing rice flour intimately with cold water, and then gently boiling it. It is beautifully white, and dries almost transparent. Papers pasted together with this cement will sooner separate in their own substance than at the joining, it is therefore extremely useful in the preparation of curious paper articles, as tea trays, ladies' dressing and work boxes, and other articles which require layers of paper to be cemented together. In every respect it is preferable to common paste made with wheat flour. It answers well for pasting into books the copies of writing taken off by copying machines on unsized silver paper. With this composition, made with a small quantity of water, that it may have a consistence similar to plastic clay, models, busts, statues, basso relievos, and the like, may be formed. When dry, the articles made of it are susceptible of a high polish; they are also very durable. The Japanese make quadrille fish of this substance, which so nearly resemble those made of mother of pearl, that the officers of our East Indiamen are often imposed upon.

**Of Sizes.**—Common size, manufactured in the same manner, and generally by the same people as glue, is glue left in a moister state, by discontinuing the evaporation before it is brought to a due consistence.

**Isinglass Size**, is prepared much in the same way as glue; the quantity of water for dissolving it is increased; and the same makes good parchment size.

**CENOTAPH**, an empty tomb erected in honour of a deceased person, and is thus distinguished from the sepulchre in which a coffin is deposited.

**CENTAURUS**, the *Bull Pricker*, as his name denotes, ranks among the old constellations. The Centaur is said to derive its name from those sons of Ixion and Nubes, whom fable represented half men, half horses; and the notions which the Americans entertained of the Spanish cavaliers, have been suggested, to persuade us that the ancients who first saw a man on horseback, conceived him and the animal to be one. The fable of the Centaurs and the *Lapithæ*, is well known to every schoolboy. The boundaries and contents of this constellation are: on the north by Hydra, east by Lupus, south by Crux, and west by Robur Caroli. There are thirty-five stars in this constellation, *viz.* two of the 1st magnitude, one of the 2d, six of the 3d, nine of the 4th, &c. The brilliants of this constellation are situated on the feet of the Horse; and with the adjoining asterism of the Cross, make a very splendid shew in southern latitudes; but the people of Britain are too far north to enjoy this sight. The star  $\beta$ , in the western foot, culminates about 7 minutes before  $\alpha$ , or at XIX ho. 1' 45", on the 1st of January, and by making an allowance of about 4 minutes for each succeeding day of the month, it will be on the meridian, January 2, at XVIII ho. 57' 21", on the 3d at XVIII h. 52' 58", on the 4th at XVIII ho. 48' 38", &c.

**CENTESM**, the 100th part of a thing.

**CENTRAL**, something relating to a centre. Thus, we have **CENTRAL Eclipse**, **CENTRAL Force**, &c. **Central Eclipse** is, when the centres of the luminaries exactly coincide, and are directly in a line with the eye of the observer. **Central Forces** are those forces which tend directly to or from a certain point or centre; or they are forces which cause a moving body to tend towards, or recede from, the centre of motion; and are hence divided into two kinds, according to their different relations to the centre, *viz.* whether it be to approach or to recede

from it; being called, in the former case, *centripetal* force, and in the latter, *centrifugal*. See **FORCE**.

**CENTRE**, in a general sense, denotes a point equally remote from the extremes of a line, surface, or solid. The word signifies a point.

**CENTRE of an ARCH.** Under the word *Bridge*, the various forms of arches were noticed. We will now shew how the archstones are supported till the arch is completed; and the most commodious and least expensive manner in which this can be accomplished.

1. When the span is small, as cellars and vaults, the foundation of the side wall is dug out, the earth rounded over upon it, the arch thrown, and the earth afterwards dug away.

2. When it is necessary to use wood for the frame or centre, we must *first* consider the weight to be supported; *secondly*, the quantity of materials to be used, that shall be of sufficient strength to support such a weight; and, *thirdly*, the most effective method to apply these materials.

*First, the Weight to be supported.*—A semicircular arch can be raised 30 degrees, (see *Bridge*,) without a centre. There are 120 degrees to support; and if the diameter be 20 feet, 120° will measure 20·94393 + feet; say 21 feet. The keystone of such an arch would be driven at 18 inches depth. The specific gravity of a cubic foot of hard stone, is 2·532. A stone 18 inches square, by 21 feet, gives 47·25 solid feet: the weight by the above specific gravity is 7477·307 lbs, or 66·753 cwt. being the weight that one rib of the centre frame must sustain.

In the span of 50 feet, the arch of 120° measures 52·36 feet; the archstone is 2½ feet deep by 2 feet, is 5 superficial feet, which + 52·36 = 261·8 solid feet and 369·908 cwt. of specific gravity. Here the weight is increased upon the centre frame in the proportion of 66·5 to 309·9; or more than five times, for the difference of the centre framework.

In the span of 100 feet, arch 104·719 feet, keystone 4 × 3, we have 1256·628 solid feet, 1775·848 cwt. specific gravity; above five times the weight of an arch of 50 feet span. In the span of 130 feet, the arch 156·13556 feet, the arch 5 × 3, as in the bridge of Dee at Aberdeen, we have 2042·0336 solid feet, and 2885·2838 cwt. the rib or beam of the frame centre. See **STRENGTH of MATERIALS**.

*Secondly*, the strength of timber requisite to support any of the foregoing weights may be ascertained thus:—In all mechanical structures, each member should not only be able to resist the strain under which it is constantly subjected, but should also be able to withstand those occasional shocks to which it is ever exposed. This is peculiarly the case in the framing of centre work for bridges. Every piece of wood employed is of a prismatic or columnar form, and is exposed either to longitudinal or transverse strain; and may be so used as to sustain a longitudinal tension, in withstanding a longitudinal compression, in resisting a transverse pressure, and in opposing the act of twisting or wrenching. But the investigation of these topics would interest few readers, and to those few the results would not be of much practical value.

A batten or prism of wood, 5 inches square, and 14 feet long, supports a weight of 5300 lbs. which may be called its breaking weight; and it has more than double the strength of a prism of 28 feet long, 5 inches square, for 1775 lbs. would break the latter. Every beam of wood becomes more liable to break by its length; 12 inches. 5 inches square, weight 10·4 lbs. more or less; and 10·4 lbs. at 13 feet distance, acts with a power of 135·2 lbs. This is the last term, and 0, the point of fracture, is the first term. The first and last multiplied by half the number of terms = the sum of all the terms; or  $135·2 \times 6\frac{1}{2} = 878·8$  lbs. added to 1775 = 2653·8, being very near the half of the force that breaks the prism of 14 feet. The weight that breaks a prism of 9 feet long and 5 inches square, is 8308. To reduce this experiment to one of greater dimensions, suppose one foot; similar solids of the same altitude are to one another as their bases; *i.e.* 25, the base of the 5 inch square is to 144, the base of 1 foot square, as the weight that would break the batten of 9 feet, to the weight that would break the batten of the same length and 12 inches square; that is, the base 25 : 8308 :: 144 : 47854 lbs. = 213·8125 tons; and the proportion, as above, for greater or less length of logs or spars. And a

batten of any depth, and one half breadth, is equally strong in that position as if it had been square timber: hence the advantage in point of economy; for if the piece is set upon edge, suppose 9 inches deep and one broad, provided it receives no lateral tension, it will bear as much strain as if 9 inches square. In general, a beam the same length and breadth as another, but twice the depth, is four times stronger; and a beam of the same depth and breadth, and double the length, is only half so strong. These experiments were made upon well-seasoned oak; but between one-third and one-half of the absolute strength of these results will do in practice.

We are now, in the *third* place, to consider the most effective method of applying these materials. The late Mr. Rennie found, that cubes of one inch are crushed by the weights annexed:—

|                              |            |
|------------------------------|------------|
| Elm, .....                   | 1·284 lbs. |
| White deal, .....            | 1·928      |
| English oak, .....           | 3·860      |
| Craighleith freestone, ..... | 8·688      |

Cubes of  $1\frac{1}{2}$  inch are, however, crushed with less loads in proportion: thus,

|                                                                 |            |
|-----------------------------------------------------------------|------------|
| Red brick, .....                                                | 1·817 lbs. |
| Yellow baked brick, .....                                       | 2·254      |
| Fire brick, .....                                               | 3·864      |
| Craighleith stone, .....                                        | 15·560     |
| White statuary marble, .....                                    | 13·632     |
| Purbeck limestone, .....                                        | 20·610     |
| Cornish granite, of which Waterloo Bridge }<br>was built, ..... | 14·302     |
| Peterhead granite, .....                                        | 18·636     |
| Aberdeen blue granite, .....                                    | 24·536     |

A pillar in the church of All Saints, at Angers, is 24 feet high and 11 inches square, supporting 60,000 lbs. which is not one-seventh of the weight that would crush it. Hence the delicacy of many pillars in Gothic buildings, and of those in the Exchange, Cornhill, London. Instead of a pier of 10 feet in a bridge of 50-feet span, one of 2 feet thick would be sufficient. How superfluous then are those enormous piers that obstruct the course of rivers.

But the inquiry is with wood; and to arrive at our conclusion, let us consider precisely the strength of an arch above a right line parallel to the horizon. An arch recedes from a perpendicular to a horizontal line, the force therefore that it will sustain, is, between the force that a body will carry in the perpendicular, and that which produces a fracture upon any material in the horizontal direction. If the perpendicular is greater than the horizontal line, it will have more of the strength of the bruising force, than of the transverse fracture. This force is explained by the ratio compounded of the bruising force and that of the transverse fracture, *i.e.* the absolute and relative force. In other words, if a geometrical mean be taken between the elevation of the arch, as pressure of absolute strength, and the length of the horizontal line, this mean will be the strength of the arch above the horizontal line.

Experiments made upon prisms of seasoned oak, 2 inches square, and 2, 4, or 6 feet high, shewed them crushed by the vertical pressures of 17,500 lbs. 10,500 lbs. and 7000 lbs.; but if 4 inches square, and of the same altitudes, they would give way under loads of only 80,000 lbs. 70,000 lbs. and 50,000 lbs. In the first set of trials, the mean cohesive power amounts to 130,000 lbs. and in the second to 520,000 lbs.

From all these reasonings it appears, that so much as the piece of wood is elevated towards the perpendicular, so much the nearer it approaches to its absolute strength, and by so much as the arch is flatter, or the piece of wood less inclined, the nearer it is to a straight line, and so much the more reduced to its relative strength; the position of the arch therefore must be in the ratio compounded of these two.

Having established these principles, let us now shew the application in practice.

Pitot's plan of an arch, as represented in the following figure, though profuse in materials, possesses great ingenuity. The arch A C D B can be raised  $30^\circ$  on each side, or to the point D, without any centre. The stretcher E E is now raised and propped by the struts A E, B E. The stretcher E E is divided into four equal parts; at the centre part the king post K F rises the

height of the intended arch. The struts A G, B G, and the tie beam G G, are previously put in; G G being one-half of E E. The bridles, 1, 2, 3, 4, &c. prevent the arch from yielding from A to C, or from B to D. The struts A C, B D, support the bridles 1, 1; 3, 3;—the struts B G, A G, support the bridles

2, 2; 4, 4; 5, 5; 6, 6,—the struts E P, D F, support the bridles 7, 7;—the struts G H, G H, support the bridles 9, 9; and the bridles 8, 8, rest on the stretcher E E. The struts E P, D F, support the king post, as do also the struts G H, G H, and the king post being well secured to the stretcher E E, supports it in the centre.

This arch we will say is 60 feet span, the archstones 7 feet long, and 3 feet broad, each cubic foot of which is 160 lbs. Let the structure be of Portland stone, which weighs 160 lbs. the cubic foot. The stretcher E E may be raised  $45^\circ$  in the place of  $30^\circ$  before the centre is put up. Therefore there are only  $90^\circ$  of arch to provide for, and the perpendicular  $d, D d$ , determines the limits of the absolute pressure upon the frame. The parts of the arch below C and D rest upon the abutments of the pier. And the weight of one course of the archstones is  $53 \times 7 \times 3 = 178,080$  lbs. But the absolute transverse strength of a plank 7 feet long and 12 inches broad, by one thick, is 189,163 lbs.; or if 2 inches thick, it would be no more. A plank 7 feet long and 8 inches square, has 47,649 lbs. of transverse strength. Therefore, the former species of scantling is the better, as it gives us an excess of 11080 lbs. more strength than is required to support that part of the arch. But 7 feet is only one-seventh part of 53 feet, the frame is therefore of sufficient strength to support the whole weight of the arch when equally divided along its whole length.

The relative proportion of the strength of oak and fir is  $\frac{1}{10}$ , therefore for every beam 8 inches square of oak,  $9\frac{1}{2}$  by  $2\frac{1}{2}$  of fir may be used.—From these principles of M. Pitot, every mechanic may construct the frame centre for any bridge.

In the centering of the *Bridge of Curvin*, as represented in the following figure, the arches are elliptical, the longer axis or span is 60 feet, the semitransverse axis or rise 20 feet, the archstones weigh 176 lbs. per cubical foot, and are 4 feet in length, which is the thickness of the arch; the truss beams

were from 15 to 18 feet long and 9 inches by 8 inches broad, of oak. There were five trusses  $5\frac{1}{2}$  feet asunder, and the whole weight of the arch amounted to 600 tons, or 112 tons for each truss; 90 tons actually pressed on each truss. But the diagonal of the parallelogram of forces drawn for these beams, is to one of the sides as 360 to 285; then  $360 : 285 :: 90 : 17\frac{1}{2}$  tons on each foot or section of 144 inches. And since every square inch of oak can bear 3 tons, there were 431 tons of strength, more than six times the pressure upon the foot beams in their longitudinal direction.

In the section A C B of this figure, we have given the centering used in erecting the bridge of Nogent, and in the section D C B that was used in the bridge of Maxence. They differ very little; but the arch of Maxence sunk 13 inches, either from the suppleness of the frame, or because the branches were not filled up as the work proceeded. The centre of Nogent would make a good arch for a wooden bridge, and the joints may all be secured by dove-tailed pieces; and the whole may be kept up at a trifling annual expense.

In the *Bridge of Neuilly*, in the following figure, the span of 120 feet has a rise of 30 feet; the arch is 5 feet thick; the strut beams  $17 \times 14$  inches; the king post  $15 \times 9$  inches; the strut beams placed in the parallel to polygons, each abutting on the king post 9 inches square.

In the *Bridge of Orleans*, in the subjoined figure, span 100 feet, rise 30 feet, the struts A, B; A' B', give great additional strength to the centre.

In *Blackfriars' Bridge*, in the following figure, the span is 100 feet, the form elliptical, the archstones at the branch 7 feet, and decreasing to the keystone. This bridge sunk only  $1\frac{1}{2}$  inches throughout, whereas all the French bridges we have mentioned sunk 11 inches upon an average.

Waterloo Bridge.

The last figure represents the centering used in the construction of Waterloo Bridge, some further details of which we have reserved for the word IRON BRIDGE.

**CENTRE** of a *Conic Section*, is that point which bisects any diameter, or that point in which all the diameters intersect each other. This point in an ellipse is within the figure, in the hyperbola without, and in the parabola it is at an infinite distance.

**CENTRE** of *Conversion*, in Mechanics, a term whose signification may be thus conceived:—If a stick be laid on stagnant water, and drawn by a thread fastened to it, so that the thread makes always the same angle with it, the stick will be found to turn about a certain point; which point is called the *centre of conversion*.

**CENTRE** of a *Curve*, of the higher kind, is the point where two diameters concur; and when all the diameters concur in the same point, it is called the *general centre*.

**CENTRE** of a *Dial*, is that point where the gnomon or style, which is placed parallel to the axis of the earth, intersects the plane of the dial.

**CENTRE** of an *Ellipse*. See **CENTRE** of a *Conic Section*.

**CENTRE** of *Equant*, in the old Astronomy, a point in the line of aphelion; being as far distant from the centre of the eccentric towards the aphelion, as the sun is from the centre of the eccentric towards the perihelion.

**CENTRE** of *Equilibrium*, is the same with respect to bodies immersed in a fluid, as the centre of gravity is to bodies in free space; or it is a certain point on which if a body, or system of bodies, be suspended, they will rest in any position.

**CENTRE** of *Friction*, is that point in the base of a body, on which it revolves; into which, if the whole surface of the base and the mass of the body were collected, and made to revolve about the centre of the base of the given body, the angular velocity destroyed by its friction would be equal to the angular velocity destroyed in the given body by its friction in the same time.

**CENTRE** of *Attraction* of a body, is that point into which, if all its matter was collected, its action upon any remote particle would still be the same, as it is while the body retains its own proper form. Or, it is that point to which bodies tend by their gravity, or about which a planet revolves as a centre; being attracted or impelled towards it by the action of gravity. The common centre of attraction of two or more bodies, is sometimes used to denote that point in which, if a particle of matter were placed, the action of each body upon it would be equal, and where it will therefore remain in equilibrio; having no tendency to move one way rather than another. This is more properly termed, by some authors, the point of equal attraction.

**CENTRE** of a *Circle*, is that point in a circle which is equally distant from every point of the circumference, being that from which the circle is described.

**CENTRE** of *Gravity* of any body, or system of bodies, is that point upon which the body, or system of bodies, acted upon only by the force of gravity, will balance itself in all positions; or it is a point which, when supported, the body or system will be supported, however it may be situated in other respects. Hence it follows, that if a line or plane passing through the centre of gravity be supported, the body or system will be also supported. And, conversely, if a body or system balance itself upon a line or plane, in all positions, the centre of gravity is in that line or plane. In a similar manner it will appear, that if a body rest in equilibrio, when suspended from any point, the centre of gravity of that body or system is in the perpendicular let fall from the centre of suspension; and on these principles depends the mechanical method of finding the centre of gravity of bodies.

*To find the Centre of Gravity of Bodies, mechanically.*—For this purpose, it is only necessary to dispose the body successively in two positions of equilibrium, by the aid of two forces in vertical directions, applied in succession to two different points of the body, and the point of intersection of these two directions will shew the centre required.

This may be exemplified by particularizing a few methods.

If the body have plane sides, as a piece of board, hang it up by any point, then a plumb-line suspended from the same point will pass through the centre of gravity, therefore mark that line upon it; and after suspending the body by another point, apply the plummet to find another such line, then will their intersection shew the centre of gravity. Or thus: hang the body by two strings from the same point fixed to different parts of the body; then a plummet hung from the same point will fall on the centre of gravity.

Another method: Lay the body on the edge of a triangular prism, or such like, moving it to and fro till the parts on both sides are in equilibrio, and mark a line upon it close by the edge of the prism: balance it again in another position, and mark another line by the edge of the prism; the vertical line passing through the intersection of these lines, will likewise pass through the centre of gravity. The same thing may be effected by laying the body on a table, till it is just ready to fall off, and then marking a line upon it by the edge of the table: this done in two positions of the body, will, in like manner, point out the centre of gravity.

To find the Centre of Gravity of certain Bodies, geometrically.—  
Prop. 1. To find the centre of gravity of two given bodies.

Let A and B be the two given bodies, take  $AG : BG :: B : A$ ; so shall G be the centre of gravity of the two bodies, as is obvious from the principle of the lever; for the bodies being suspended on the point G, they will remain in equilibrio.—In other words, the distances AG, BG, from the common centre of gravity, are reciprocally as the weights of the bodies A and B; for, if  $AG = 4$ ,  $BG = 6$ , and the ball B = 2, then the ball A = 3, because  $4 : 6 :: 2 : 3$ .

Prop. 2. To find the centre of gravity of a triangle, ABC. Bisect any two sides, AC, CB, in the points D and E, join AE, BD, and the point of intersection G will be the centre of gravity of the triangle. This is obvious, because the triangle would balance itself on each of the lines AE, BD; for these bisecting the line BC, AC, bisect every parallel section, and therefore the weight on each side is equal, and equally distant from these lines.

3. To find the centre of gravity of a trapezium. Divide it into two triangles, and find the centre of gravity of each; and then, by prop. 1, the centre of gravity of these two, which will be the centre of gravity of the trapezium. And in the same manner may be found the centre of gravity of any right-lined figure.

When from the centre of gravity of any body we let fall a line perpendicular to the horizon, that line is called the *line of direction*, the property of which is, that when it falls within the base upon which the body stands, the body cannot fall, but if it falls *without* the base, the body will tumble. Thus, in the inclining body AB, CD, as in the annexed figure, the centre of gravity is E, and the body stands firmly on its base, CDIK, because the line of direction EF falls within the base. But if the weight, as AB, GH, be laid upon the top of the body, the centre of gravity is raised to L; and then, as the line of the direction LD falls without the base at D, the centre of gravity L is not supported, and the body and weight will tumble. Hence is obvious the danger of rising hastily in a coach or boat, when it is likely to overset. By so doing, the centre of gravity is liable to be thrown out of the base, and the vehicle or boat overset. The proper conduct of passengers in such circumstances is to lie down in the bottom, and bring the line of direction, and consequently the centre of gravity, within the base. Coaches are now built so as to confine the centre of gravity within the base upon the most uneven roads. The mechanical motions of animals ought to be regulated on these principles; for when

the line of direction falls within the base of our feet, we stand, and most firmly, when it is in the middle of the body, as A, in the human figure; but when it is out of the base, we immediately fall. When you endeavour to rise from a seat, you thrust forward your body, and draw your feet backward, till the vertical line from the centre of gravity falls just before your feet; this enables you to rise, and prevents you falling forward; you advance one of your feet, till the vertical line of direction is brought between your feet, in consequence of which you may stand firmly. When a man, BC, as shewn in the following figure, endeavours to walk, he first extends his hindmost leg and foot, S, almost to a straight line, and at the same time bends a little the knee, H, of his fore leg. Thus

his hind leg is lengthened, and his fore leg shortened, and by this means his body is moved forward, till the centre of gravity, V, falls beyond the fore foot B; and then being ready to fall, he presently prevents it, by taking up the hind foot, and by bending the joints of the hip, knee, and ankle, and suddenly translating it forward to T beyond the centre of gravity, and thus he gains a new station. After the same manner, by extending the foot and leg H B, and thrusting forward the centre of gravity beyond the foot S, and then translating the foot B forward, he gains a third station; and thus walking is continued at pleasure. His two feet do not go in one right line, but in two lines parallel to one another; therefore, a man walking has a libratory motion from one side to the other; and it is not possible to walk in a right line. We walk on level ground easily and pleasantly; it is laborious to climb a hill, from the great flexure required of the joints to ascend, and from the stress they receive from the weight of the body in that position. In *walking* we always set down one foot before the other be taken up; and therefore at every step we have both feet on the ground at once. But in *running* we never set one foot down till the other be up; so that at every step we have but one foot on the ground, and all the intermediate time none. The walking of birds is not unlike that of man; only their weight is entirely supported by the strength of the muscles, since their joints are always bent. The feet of birds are also moved in two parallel lines. The motions of quadrupeds are the same as those of men.

When a *beast*, a horse for example, *stands*, the line of gravity must fall within the quadrilateral made by his four feet. When he *walks*, he has always three feet on the ground, and one up, as you see in the figure. Thus, suppose he first lift the hind foot C. Before he does this, by extending his leg backwards, he

thrusts forward his body and the centre of gravity; then taking up the foot C he moves it forward to F. Then he directly takes up the fore foot B on the same side, and carries it to H; then he takes up the hind foot D, and translates it forward; and then the fore foot A; then C again, and so on. Let any person try to walk on all-fours, and one hand and one leg on one side, one hand and one leg on the other, is the natural action of the horse in walking. When the horse *trots*, he takes up two feet together, and sets down two together, diagonally opposite. When he *gallops*, he takes up his feet one by one, and sets them down one by one; though some

Animals strike with the two fore feet nearly at once, and the two hind feet nearly at once; and have not above two feet on the ground at once. Animals of six or more feet, as the caterpillar, take up the hindmost first, then the next, and then the next in order to the foremost, *all on one side*; and after that, *all the feet on the other side*; in the same order, beginning at the last. If the caterpillar were to take up its foremost feet first, it would move backwards, as we see a crab do on the sea-shore.

Dogs, and other four-footed animals, find it difficult to stand upon their hind legs, as the centre of gravity lies too far forward, the heads of all animals being heavy, in proportion to other parts of the body.

In the duck, the goose, and the swan, who are adapted for swimming, the centre of gravity lies pretty far forward; hence they walk awkwardly, and do not seem at ease but when in the water. Hawks have the centre of gravity so far forward, that when they light on the rocks they are obliged to stand with their heads up, somewhat in the manner of dogs. If they were to put themselves in any other position, they would fall forward. Penguins are similarly formed, and their weight sinks them so deep in the water, that a stream passes between the neck and the body. In cats, and animals that spring upon their prey, the centre of gravity is so situated that they uniformly fall upon their feet. When dropping from a height, they hang down the fore and hind feet and tail, so as to bring the centre of gravity to the point below their breast, which, descending first, makes them fall as they do. Fasten a piece of lead or stone to the string of a bent bow, and toss the whole in the air, that part will come down first, and the back of the bow will never do so. The same cause acts in the case of cats and other animals of prey.

We are told by voyagers, and writers on natural history, that tortoises are taken in warm climates whilst floating in a drowsy state on the surface of the waves. A man throws himself out of the boat, and lays hold of the tortoise by the tail, and by his weight keeps it from diving, which gives his companions time to lay hold and drag it into the boat.

**CENTRE of Gyration**, of a body, or system of bodies, is that point into which, if the whole mass were collected, a given force applied at a given distance from the axis of suspension, would produce the same angular velocity in the same time, as if the bodies were disposed at their respective distances. This point differs from the centre of oscillation only in this, that in the latter case the motion is produced by the gravity of the body or of its particles, but in the case of the centre of gyration the body is put in motion by some other force acting at one place only. The distance of the centre of gyration from the axis of motion, is a mean proportion between the distance of the centre of gravity and oscillation from the same axis. Hence, when any two of these distances are known, the third may be readily determined.

**CENTRE of Magnitude**, the point equally distant from the similar external parts of a body.

**CENTRE of Motion**, that point which remains at rest while all the other points of a body move about it. And this is the same in uniform bodies of the same matter throughout, as the centre of gravity.

**CENTRE of Oscillation**, is that point in the axis of suspension of a vibrating body, in which if all the matter of the system were collected, any force applied there would generate the same angular velocity in a given time, as the same force at the centre of gravity, the parts of the system revolving in their respective places. Or, since the force of gravity upon the whole body may be considered as a single force, equivalent to the weight of the body, applied at its centre of gravity; the centre of oscillation is that point in a vibrating body, into which if the whole mass were concentrated, and attached to the same axis of motion, it would then vibrate in the same time the body does in its natural state. The centre of oscillation cannot fall within a cone, unless the altitude be greater than the semidiameter of the cone's base; and when the altitude and semibase are equal, the centre of the base is the centre of oscillation; but when the semidiameter of the base exceeds the altitude, it always falls below the base.

**CENTRE of Percussion**, in a moving body, is that point where the percussion or stroke is the greatest, in which the whole

percussive force of the body is supposed to be collected; or about which the impetus of the parts is balanced on every side, so that it may be stopped by an immoveable obstacle at this point, and rest on it without acting on the centre of suspension.

1. When the percussive body revolves about a fixed point, the centre of percussion is the same with the centre of oscillation; and is determined in the same manner, *viz.* by considering the impetus of the parts as so many weights applied to an inflexible right line void of gravity; namely, by dividing the sum of the products of the forces of the parts multiplied by their distances from the point of suspension, by the sum of the forces. The centre of percussion in a cylinder is at  $\frac{3}{4}$  of its length from the point of suspension; or a stick, of a cylindrical figure, supposing the centre of motion at the hand, will strike the greatest blow at a point about two-thirds of its length from the hand.

2. But when the body moves with a parallel motion, or all its parts with the same celerity, then the centre of percussion is the same as the centre of gravity. For the momenta are the products of the weights and celerities; and to multiply equiponderating bodies by the same velocity, is the same thing as to take equimultiples; but the equimultiples of equiponderating bodies do also equiponderate, therefore equivalent momenta are disposed about the centre of gravity, and consequently in this case the two centres coincide, and what is true of the one will hold in the other.

**CENTRE Phonic**, in Acoustics, is the place where the speaker stands in polysyllabical and articulate echoes.

**CENTRE Phonocampic**, is the place or object that returns the voice.

**CENTRE of Position**, in Mechanics, denotes a point of any body, or system of bodies, so selected that we may properly estimate the situation and motion of the body, or system, by those of this point. It is evident, that in mechanical discussions, the point, by the position of which we estimate the position and distance of the whole, must be so determined that its position and distance of the whole, estimated in any direction whatever, shall be the average of the positions and distances of every particle of the mass estimated in the same direction. Accordingly, this will be the case, if the point be so selected that when a plane is made to pass through it in any direction whatever, and perpendiculars are drawn to this plane from every particle in the body or system, the sum of all the perpendiculars on one side of this plane is equal to the sum of all the perpendiculars on the other side.

**CENTRE of Pressure**, or *Meta Centre* of a fluid against a plane, is that point against which a force being applied equal and contrary to the whole pressure, it will sustain it, so as that the body pressed on will not incline to either side. This is the same as the centre of percussion, supposing the axis of motion to be at the intersection of this plane with the surface of the fluid; and the centre of pressure upon a plane parallel to the horizon, or upon any plane where the pressure is uniform, is the same as the centre of gravity of that plane.

**CENTRE of spontaneous Rotation**, is that point which remains at rest the instant a body is struck, or about which the body begins to revolve. If a body of any size or form, after rotatory or gyratory motions, be left entirely to itself, it will always have three principal axes of rotation, that is, all the rotatory motions by which it is effected may be constantly reduced to three, which are performed round three axes perpendicular to each other, passing through the centre of gravity, and always preserving the same position in absolute space, while the centre of gravity is at rest, or moves uniformly forward in a right line.

**CENTRE Velic, Velique, or Velic Point**, is the centre of gravity of an equivalent sail, or that single sail whose position and magnitude are such as cause it to be acted upon by the wind when the vessel is sailing, so that the motion shall be the same as that which takes place while the sails have their usual positions.

**CENTRIFUGAL PUMP**, a very curious machine for raising water by means of a centrifugal force combined with the pressure of the atmosphere. It consists of a large tube of copper, &c. in the form of a cross, which is placed perpendicularly in the water, and rests at the bottom on a pivot. At the upper

part of the tube is an horizontal cog-wheel, which touches the cogs of another in a vertical position; so that by the help of a double winch the whole machine is moved round with very great velocity. Near the bottom of the perpendicular part of the tube is a valve opening upwards; and near the two extremities, but on the contrary side of the arms or cross part of the tube, are two other valves opening outwards. These two valves are, by the assistance of springs, kept shut till the machine is put in motion, when the centrifugal velocity of the water forces them open, and discharges itself into a cistern or reservoir placed there for that purpose. On the upper part of the arms are two holes, which are closed by pieces screwed into the metal of the tube. Before the machine can work, those holes must be opened, and water poured in through them, till the whole tube be full; by these means all the air will be forced out of the machine, and the water supported in the tube by means of the valve at the bottom. The tube being thus filled with water, and the holes closed by the screw-caps, it is turned round by means of the winch, when the water in the arms of the tube acquires a centrifugal force, opens the valves near the extremities of the arms, and flies out with a velocity nearly equal to that of the extremities of the said arms. This machine cannot raise water higher than 32 feet; because its action depends upon the weight of the atmosphere, and, on shipboard, is much inferior to the chain-pump.

**CENTRIFUGAL FORCE**, is that force by which a body revolving about a centre, or about another body, has a tendency to recede from it.

**CENTRIPETAL FORCE**, is that force by which a body is perpetually urged onwards to a centre, and thereby made to revolve in a curve instead of a right line.

**CENTURY**, any thing divided or ranged into periods of hundreds. Thus we say, such a century of the Christian era, meaning so many hundred years since the commencement of that era, and which is necessarily one more than the number of years mentioned in the date: the present is the 19th century, which commenced on the 1st of January, 1801.

**CEPHEUS**. This constellation perpetuates the memory of an ancient king of Ethiopia, or India, said to be the father of Andromeda, and husband of Cassiopeia. *Hyk* (a king) was the old Ethiopian name for this asterism, which the Arabians call *Keiphuz*, and *Cheic*, an evident corruption from the Greek.—The boundaries and contents are: north by the pole of the world, east by Cassiopeia and Tarandus, south by Lacerta and Cygnus, and west by Draco. Right ascension  $8^{\circ}$ , and declination  $60^{\circ}$  north. It contains 35 stars, viz. three of the 3d magnitude, seven of the 4th, &c. Alderamin,  $\alpha$ , having  $318^{\circ} 33' 55''$  right ascension, and  $61^{\circ} 49' 28''$  north declination, culminates, at London, on the first day of every month, as shewn in the following table: Meridian Altitude  $79^{\circ} 41' 32''$  north.

**CETUS**, the *Whale*, is pretended by the Greeks to be the sea monster which Neptune, brother to Juno, sent to devour Andromeda, because her mother, Cassiopeia, had boasted herself to be fairer than Juno and the Nereides; and it was placed among the stars, when Perseus, to save that princess, struck it dead, by presenting to its view the head of Medusa. The name of this constellation is found long prior to the time of Perseus. When the equinoctial sun in Aries opened the year, it was denominated the *preserver* or *deliverer*, by the idolaters of the East. The constellation of the Whale is called *Nux* in Chaldaic, and *Nuxa* in Syriac. Now the head of Cetus is placed immediately under the *Ram*, and always rises and sets with that sign, but the rest of the constellation rises before Aries. On this account, it has been suggested, that the *Ram* was metaphorically called the son of that constellation, which is next to it, and which rises immediately before it.—The boundaries and contents of this constellation are: north by Pisces and Aries, east by Eridanus, Orion, and Taurus, south by Fornax Chemica and Officina Sculptoris, and west by Aquarius. This constellation occupies the greatest space of any in

the firmament. It contains 97 stars, of which two are of the 2d magnitude, eight of the third, nine of the 4th, &c. The brilliant in this constellation is *Menkar*, situated in the upper mandible, and of the 2d magnitude, having  $43^{\circ} 12' 59''$  north, right ascension, and  $3^{\circ} 22' 50''$  declination north. This star appears in the horizon, at London, on E. by N.  $\frac{1}{2}$  E. point of the compass, and rises and culminates as in the following table: Meridian Altitude  $41^{\circ} 51' 50''$ .

**CHAFF MACHINE**, as represented in the following figure, is used for cutting straw for horses and cattle. This machine consists of a wooden frame, supported by four legs, and on this frame is a box to hold the straw, about 5 feet long and 10 inches broad. On the wheel B is fixed a knife A, and in every revolution of the wheel the knife passes the end of the box, and cuts the straw into chaff. The straw is fed by two rollers connected with the machinery in the side of the box, and worked usually by a wheel, whose teeth work in an endless screw. The whole is worked by the hand, which grasps the winch C. This is Baker's chaff-cutter. Pike's is somewhat different.

**CHAIN**, an instrument used in surveying, of which there are three different kinds, but that which is most commonly employed for this purpose, is the *Gunter chain*, so called from the name of its inventor. This chain is 4 poles, or 66 feet long, and is divided into 100 square lengths, or links, each link being 7.92 inches in a link. 1 square chain = 10000 links = 16 poles; 10 square chains = 100000 links = 160 poles = 1 acre.

Hence we have the following easy method of converting links or chains to acres:—From the number of links point off five figures to the right hand for decimals, and those on the left will be acres; multiply the decimals by 4, and point off again five places for decimals, and those on the left will be rods; multiply these decimals by 40, and point off the decimals as above, and the figures on the left will be poles, or perches, which is commonly the lowest denominator. See SURVEYING.

**CHAIN-PUMP**, a well-known hydraulic machine for raising water. It is usually made from 12 to 25 feet in length, and consists of two collateral square barrels, and an endless chain of pistons of the same form fixed at proper distances. The chain is moved round a coarse kind of wheelwork, fixed sometimes at one end, but often at both ends of the machine. The teeth of the wheelwork are so contrived as to receive one half of the flat pistons, and let them fold in; and they take hold of the links as they rise. A whole row of the pistons (which go free of the sides of the barrel by about a quarter of an inch) are always lifting when the pump is at work; and, as this machine is generally worked briskly, the pistons or pallets bring up a full bore of water in the pump. Chain-pumps are wrought sometimes by men turning winches, sometimes by horses, and some-

times by the impulse of a stream of water; they are likewise so contrived, that by the continual folding in of the pistons, stones, dirt, or whatever comes in the way, may be cleared off; they are therefore often used to drain ponds, sewers, and remove foul water, when no other pump could be employed.

Chain-pumps are not merely fixed in a vertical position, but are often inclined; and in the latter case they are in a state of the greatest perfection, or raise the most water, when the breadth of the pallets is equal to their distance from each other, and the plane is inclined under an angle of  $24^{\circ} 21'$ . The Chinese method of working the chain-pump resembles the operation of the tread-mill.

It is not unusual for chain-pumps to be erected without a barrel to receive the pistons, after the manner represented in the figure. The pallets are converted into square boxes S, S, &c. which are raised by means of hexagonal axles, each side of the hexagon being equal to the distance from box to box; the boxes descend with their mouths downwards, and so enter the water.

Another contrivance for raising water, similar to the chain-pump, is an endless rope, with stuffed cushions hung upon it, which, by means of two wheels or drums, are caused to rise in succession in the same barrel, and to carry water with them. From the resemblance of this apparatus to a string of beads, it is usually called *paternoster-work*. But in this, as well as the chain-pump, the magnitude of the friction is a formidable practical objection.

**CHAINS**, strong links or plates of iron, the lower ends of which are bolted through a ship's side to the timbers: they are placed at short distances from each other on the ship's outside, as being used to contain the blocks, called dead-eyes, by which the shrouds of the masts are extended.

**CHAIN-SHOT**, a particular kind of shot, formed by fastening two cannon-balls together with a short chain, and designed to mangle and ruin a ship's sails and rigging.

**CHAIN-WALES**, or **CHANNELS**, broad and thick planks projecting horizontally from the ship's outside, beginning abreast of, and continuing somewhat abaft each mast. They are formed to extend the shrouds from each other, and from the axis, or middle of the ship, so as to give a greater security and support to the masts, and to prevent the shrouds from rubbing against the gun-wale. Every mast has its chain-wales, which are either built above or below the second-deck ports in a ship of the line; they are strongly connected to the side by knees bolts, and standards, besides being confined thereto by the chains, whose upper ends pass through notches on the outer edge of the chain-wales, so as to unite with the shrouds above.

**CHALDRON**, an English dry measure of capacity, mostly used in measuring coals. The chaldron contains 36 bushels, and weighs about 28 cwt. By act of parliament, the Newcastle chaldron is to weigh 52½ cwt., and this is to the London chaldron in the ratio of 15 to 5, which gives 28 cwt. for the London chaldron, as above stated.

**CHAMELEON**, *THE*, in Astronomy, is a small asterism by the roots of Robur Caroli, at the south pole, and contains ten stars, none of which exceed the 5th magnitude.

**CHANCES**, an interesting branch of the modern analysis, which treats of the probability of certain events taking place, by contemplating the different ways in which they may happen or fall. The doctrine of chances is a subject of which the

ancients seem to have had no idea; the discovery of it is wholly due to the moderns; but, like most other theories, it has grown into a science by such imperceptible degrees, that we can scarcely say to whom we are indebted for the first invention. But the various circumstances and limitations under which events may happen, render it impossible to reduce the laws of chance to a few determined rules and principles, as is done in various other branches of analysis; much must necessarily be left to the judgment of the analyst, and no subject requires more his care and attention. We cannot in this place enter upon the subject further than to observe, that the probability of casting an ace with a single die in one throw is  $\frac{1}{6}$ , of casting an ace or deuce is  $\frac{2}{6}$ , and so on. Again, the probability of drawing an ace out of a complete pack of cards is  $\frac{1}{13}$  or  $\frac{4}{52}$ . For there are four aces and 52 cards, or 4 chances for the event happening, and 52 for its happening and failing.

**CHANGES**, in Mathematics, denote the various arrangements that may take place in the order or situation of a given number of things; and is distinguished from the more general term *Permutations*, in this; that in the latter there may be any number of things, and any number taken at a time; while in the former, the whole number is always supposed to enter. The whole number of changes that a given number of things  $n$  admits of, is equal to the continued product  $1.2.3.4. \dots n$ ; thus the number of changes of  $6$  things  $= 1.2.3.4.5.6 = 720$   
 $7$  things  $= 1.2.3.4.5.6.7 = 5040$

See *PERMUTATION* and *COMBINATION*.

**CHANNEL**, in Hydrography, the deepest part of a river, harbour, or strait, which is most convenient for the track of shipping; also, an arm of the sea running between an island and the main or continent, as the British channel, &c.

**CHARACTERS**, in Mathematics, are certain symbols introduced in order to represent either quantities or operations. *Algebraical Characters* are those used to denote operations, equalities, proportions, &c. See *ALGEBRAICAL DEFINITIONS*. *Astronomical Characters* are those used to denote the *Aspects*, *Planets*, *Signs*, &c. *Geometrical and Trigonometrical Characters*. See *GEOMETRY* and *TRIGONOMETRY*. *Numeral Characters* are those used to represent numbers.

**CHARGE**, in Electricity, in a strict sense, denotes the accumulation of the electric matter on one surface of an electric, as a pane of glass, Leyden phial, &c. whilst an equal quantity passes off from the opposite surface.

**CHARGE**, in Gunnery, is the quantity of powder and ball, or shot, put into a piece of ordnance, in order to prepare it for execution. Different charges of powder, with the same weight of ball, produce different velocities in the ball, which are in the subduplicate ratio of the weights of powder; and when the weight of powder is the same, and the ball varied, the velocity produced is in the reciprocal subduplicate ratio of the weight of the ball; and thus corresponds both to theory and practice. This, however, is on a supposition that the gun is of an indefinite length; whereas, on account of the limited length of guns, some variation from this law occurs in practice, as well as in theory; in consequence of which it appears, that the velocity of the ball increases with the charge only to a certain point, which is peculiar to each gun, where the velocity is the greatest; and that, by farther increasing the charge, the velocity is gradually diminished, till the bore is quite full of powder. The length of the charge producing the greatest velocity, ought to be about  $\frac{1}{4}$ ths of the length of the bore. But for several reasons, the length of the charge producing the greatest velocity falls short of this, and the more so as the gun is the larger. From many experiments it has been found, that the length of the charge producing the greatest velocity, in guns of various lengths of bore, from 15 to 40 calibers, is as follows:

| Length of Bore in Calibers. | Length of Charge for greatest Velocity. |
|-----------------------------|-----------------------------------------|
| 15 .....                    | $\frac{1}{4}$                           |
| 20 .....                    | $\frac{1}{5}$                           |
| 30 .....                    | $\frac{1}{6}$                           |
| 40 .....                    | $\frac{1}{7}$                           |

In practice, however, the charge which produces the greatest velocity, is not that which produces the greatest effect, at least in battering down the gates, &c. of fortified places, and in naval actions; for the balls, in these cases, penetrate and pass

quite through, and therefore communicate to the objects they strike against, only a part of their momentum.

**CHARLES'S WAIN**, a name given by some old astronomical writers to the constellation *Ursa Major*.

**CHART**, or **SEA CHART**, a hydrographical or sea map, for the use of navigators; being a projection of some part of the sea in plano, shewing the sea-coasts, rocks, sands, bearings, &c. Fournier ascribes the invention of sea charts to Henry, son of John, king of Portugal. These charts are of various kinds, the plain chart, Mercator's or Wright's chart, the globular chart, &c. In the construction of charts, great care should be taken that the several parts of them preserve their position to one another, in the same order as on the earth; and it is probable, that the finding out of proper methods to do this gave rise to the various modes of projection.

There are many ways of constructing maps and charts; but they depend chiefly on two principles. First, by considering the earth as a large extended flat surface; and the charts made on this supposition are usually called plain charts. Secondly, by considering the earth as a sphere; and the charts made on this principle are sometimes called globular charts; Mercator's charts resemble a cylinder unrolled; and to these hydrographical maps we more properly give the epithet *chart*.

**Plain CHARTS** have the meridian, as well as the parallels of latitude, drawn parallel to each other, and the degrees of longitude and latitude every where equal to those at the equator. And therefore such charts must be deficient in several respects. For, first, since in reality all the meridians meet in the poles, it is absurd to represent them, especially in large charts, by parallel right lines. Secondly, as plain charts shew the degrees of the several parallels as equal to those of the equator, therefore the distances of places lying east and west must be represented much larger than they really are. And, thirdly, in a plain chart, while the same rhumb is kept, the vessel appears to sail on a great circle, which is not really the case. Yet plain charts made for a small extent, as a few degrees in length and breadth, may be tolerably exact, especially for any part within the torrid zone; and even a plain chart made for the whole of this zone will differ but little from the truth.

**Mercator's CHART**, like the plain charts, has the meridians represented by parallel right lines, and the degrees of the parallels, or longitude, every where equal to those at the equator, so that they are increased more and more, above their natural size, as they approach towards the pole; but then the degrees of the meridians, or of latitude, are increased in the same proportion at the same part; so that the same proportion is preserved between them as on the globe itself. This chart has its name from that of the author, Girard Mercator, who first proposed it for use in the year 1556, and made the first charts of this kind, though they were not altogether on true or exact principles, nor does it appear that he perfectly understood them. Neither, indeed, was the thought originally his own, of lengthening the degrees of the meridian in some proportion; for that was hinted by Ptolemy two thousand years ago. It was not perfected, however, till about the year 1590, when Mr. Wright shewed a ready way of constructing it, by enlarging the meridian line by the continual addition of the secants.

**Globular CHART**, is a projection so called from the conformity it bears to the globe itself. This is a meridional projection, in which the parallels are equidistant circles, having the pole for their common centre, and the meridians curvilinear and inclined, so as all to meet in the pole, or common centre of the parallels. By which means the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same as on the globe itself; which renders it a good method for geographical maps.

**Hydrographical CHARTS**, are sheets of large paper, on which several parts of the land and sea are described, with their respective coasts, harbours, sounds, flats, rocks, shelves, sands, &c.; also the points of the compass, and the latitudes and longitudes of the places.

**Selenographic CHARTS**, are particular descriptions of the appearances, spots, and maculæ of the moon.

**Topographic CHARTS**, are draughts of some small parts only of the earth, or of some particular place, without regard to its relative situation, as London, York, &c.

**CHEMISTRY**, investigates the effects of the action of bodies upon each other, with the view of determining their constituent principles, and forming new compounds. The extensive utility of this science is shewn by its immediate connexion with the arts, subservient to the subsistence or the comforts of man. Dyeing, bleaching, tanning, glass-making, the working of metals, &c. are chemical operations. In agriculture its use is very important, because it explains the phenomena of the growth and nourishment of vegetables, and the nature and action of manures, &c. The culinary arts, the arts of baking, brewing, distilling, &c. owe their improvement to chemistry. In medicine, it affords invaluable assistance, by giving the medical man a knowledge of the various substances used as medicines. In short, there is scarcely any art, trade, or manufacture that does not depend, either immediately or remotely, upon a knowledge of this science. Besides, it enlarges the mind, by affording us a more extensive and intimate knowledge of nature, and procures for us some of the most sublime pleasures and rational enjoyments. Before we proceed to the theory, we shall describe the principal processes employed in chemical experiments: these are—

1. Trituration. 2. Sifting. 3. Washing. 4. Filtration. 5. Decantation. 6. Lixivation. 7. Evaporation. 8. Distillation. 9. Sublimation. 10. Crystallization. 11. Solution. 12. Precipitation. 13. Fusion. 14. Cupellation. 15. Digestion. 16. Saturation. 17. Combustion. 18. Deflagration. 19. Detonation. 20. Operations in the dry way. 21. And in the humid way.

**Mechanical Operations for the Division of Bodies.**—Trituration, Pulverization, and Levigation, (or the reduction of solids into powders of different degrees of fineness,) are necessary and preliminary operations, previous to the solids being chemically acted upon. Brittle substances are reduced to powder by means of hammers, pestles and mortars, and stones and mullers. The annexed cut represents a pestle and mortar. Fibrous substances, as wood, the horns of animals, elastic gum, and metals, which flatten under the hammer, cannot be reduced to powder by the foregoing methods; for these, files, rasps, knives, and graters, are used.

**Sifting.** The separation of the finer parts of bodies from the coarser, which may want farther pulverization, is performed by sifting or washing. A sieve consists of a cylindrical band of thin wood, or metal, having silk, leather, hair, or wire, plaited or woven, and stretched across it. Sieves are of different degrees of fineness.

**Washing**, is employed for procuring powders of an uniform fineness, more accurately than by the sieve; but it can only be used for substances that are not acted upon by the fluid which is used in the washing.

**Filtration**, is a finer species of sifting, through the pores of paper, flannel, fine linen, sand, pounded glass, porous stones, and the like. It is used for separating fluids from solids, or gross particles that may happen to be suspended in them, and not chemically combined with the fluids. Thus, salt water cannot be deprived of its salt by filtration; but muddy water will deposit its mud.

**Decantation**, separates solid particles which are diffused through liquors. These are allowed to settle to the bottom, and the clear fluid is gently poured off. If the sediment be extremely light, and apt to mix again with the fluid by the slightest motion, a syphon is used for drawing off the clear fluid.

**Lixivation**, is the separation by water, or some other fluid, of such substances as are soluble in that fluid, from other substances that are not soluble in it. If a mineral consisting of salt and sand, or salt and clay, &c. be broken to powder and thrown into water, the salt will be dissolved and kept suspended, whilst the earthy matter will fall to the bottom of the vessel, and, by means of filtration, may be separated from the fluid.

**Evaporation**, separates a fluid from a solid, or a more volatile fluid from another less volatile. Evaporation is used when the more volatile or fluid substance is not to be preserved, and various degrees of heat are employed for this purpose, according to the nature of the substances. Evaporation is performed in vessels of wood, glass, metal, porcelain, &c. of a flat shape, to expose the liquids as extensively as possible to the action of heat: evaporating vessels may be placed either over the naked

fire, or in a vessel filled with sand, called a sand-bath; or they may be left in a warm room.

**Distillation.** When the fluid which is evaporated must be preserved, the operation is called distillation, which is nothing more than evaporation in close vessels, to separate two fluids of different degrees of volatility, and preserve the most volatile, or both of them. The substance to be subjected to distillation is put into some vessel that will resist the action of heat, called a retort. See the annexed figure, of which A is the retort, and B a vessel for receiving the product of distillation; the latter is called the receiver. *a* is called the turbulure, having a glass stopper, by which the substance intended for distillation is poured into the retort; *b* is the neck of the receiver, into which the beak of the retort enters. Alembics and stills having beaks in the same way, are used for sublimation and distillation. The vessel that contains the liquor to be distilled is placed upon the fire, or in a sand bath, or over a lamp; the heat causes the volatile fluid to rise in the form of vapour and pass into the receiver, where it is again condensed by cold. This condensation may be assisted by making the vapour pass through a tube which is immersed in a vessel containing cold water, and called the refrigeratory. The above represents a still in action; A is the end of the tube from whence the distilled fluid escapes.

**Sublimation.** When the materials which are evaporated concrete in a solid form within the neck of the distilling vessels, the operation is called sublimation, and is performed in an alembic, which the annexed figure represents. A is the cucurbit or boiler; B is the head or capital; C is a glass tube through which the sublimed substances pass into D, the receiver. The following beautiful experiment, illustrated by an engraving, will amply explain the operation of sublimation. Procure a bell-glass, a sprig of rosemary, a flat circular piece of iron or copper, and two drachms of Benzoic acid. Heat the iron nearly to redness, sprinkle the acid on it, and invert the bell-glass, with the rosemary sprig in it, over the whole. The acid will arise or be sublimed in dense fumes, and will be precipitated or settled on the cool branches of the rosemary, in the form of a beautiful hoar frost.

**Crystallization.** When a salt is dissolved in water, or other fluid, and by evaporation the fluid is driven off, the salt gradually acquires a solid form, and in doing this, it arranges its particles in a particular manner; and they are then said to be crystallized. Some salts arrange themselves in the forms of pyramids, some of prisms of different kinds, &c. Vessels of earthenware or glass are employed for such crystallizations; and they must be kept perfectly still, and well defended from dust or accidents.

**Solution.** When a salt is mixed with water, it loses its state of solidity, the particles of salt are divided, and unite themselves to those of the water, forming a liquid of which all the parts are homogeneous, or of the same kind. In this process neither the salt nor the water is decomposed, and the salt may be recovered again in its original state and quantity, by driving off the water by evaporation. The same takes place when resin is mixed with spirits of wine. The solution of metals by acids, is, however, of a different nature; here one of the substances is altered, and different products are obtained. Vessels of glass are used for solution. The liquid used for dissolving a metal, or other solid substance, is usually called a solvent.

**Precipitation,** is the recovery or separation of a body from its solvent, by the addition of a third substance, so that the former may re-appear in a solid state. The substance thus recovered, is called a precipitate, and the superadded body that occasions this precipitation, is called a precipitant.

**Fusion.** The melting or causing any body to pass from the solid to the liquid state, by the action of fire, is called fusion.

The fusion of metallic substances requires vessels which will resist destruction by fire. Those vessels called crucibles are mostly, if not always, made of earthenware, or porcelain, or a mixture of clay and powder of black-lead. Some of these are barrel-shaped, as A; others are indented at the side, to allow their contents to be poured out, as B, and others have lids fitted to them, to prevent the sublimation or dispersion of volatile substances, such as arsenic, &c. as C.

**Furnaces** For fusion, we find it necessary to employ furnaces, or the blow-pipe. The various degrees of heat required for the performance of chemical operations, render a variety of fireplaces or furnaces necessary for a chemist. Furnaces are either open at top, or covered with what is called a dome, and have a chimney or tube to carry off the heated air, smoke, &c. They are sometimes supplied with air from the natural action of the fire, which rarefies the air about the ignited fuel; and which becoming specifically lighter, ascends into the chimney, whilst the colder or heavier air is forced by the atmosphere to enter at the lower part of the furnace. Some furnaces are supplied with air by means of bellows, and those are applied to the forging of iron, or for reducing metals from their ores; this is called smelting. Hence furnaces derive their various names, and are called *simple or open furnaces, reverberatory furnaces, the furnace for distilling by a sand heat, the cupelling or enamelling furnace, and the wind or air furnace*, which the engraving represents; *a* being the ash-pit, *c* the fire containing a crucible, *d* is a moveable cover, to be taken off or put on at pleasure. There are also *blast furnaces, forges, smelting furnaces, &c.*

For common purposes, portable furnaces are used. They are extremely useful for a variety of purposes in the small way; as in distillation, fusion, sublimation, cupellation, &c. &c. In the engraving of one of these furnaces, B is the fireplace, C the ash-pit, and D the chimney.

Blow-pipes are used for diverting the flame of a candle or lamp against any bit of ore or other substance, required to be examined. They ought to have a bulb upon the middle of their stems (according to the figure) to contain the moisture that is formed from the breath. The compound gas blow-pipe, which has been

a late discovery, is perhaps the most generally useful instrument a chemist can possess. See BLOWPIPE.

Cupellation, or the art of assaying metals and ores, is performed in a shallow crucible made of burnt bones. The impure metal or ore is put into the cupel (of which the annexed is a figure) with some oxidizable metal, such as lead. The cupel is now put into a muffle, and the whole is submitted to the heat of a furnace. The flame passes over the cupel, oxidating the lead, which combines with the base part of the metal to be assayed, and leaves the pure metal (such as gold or silver) in the shape of a button at the bottom.

Digestion. When a solid substance, in powder or otherwise, is left for a certain time in a fluid, and the mixture is kept exposed to a slow degree of heat, the process is called digestion.

Saturation. When one substance which has an affinity to another, is mixed with as much of that other substance as its affinity will enable it to hold in combination, then the former substance is said to be saturated, or the mixture to have attained the point of saturation. If the mixture contain a greater proportion of either substance, it is said to contain an excess, or to be surcharged. The same thing must be understood of the compounds of more than two substances.

Combustion, is when a body is in the act of burning in any air or gas capable of supporting flame.

Deflagration, is when the combustion is attended with explosions or cracklings.

Detonation, is a pretty loud report.

*Operations in the Dry, and Humid Way.*—When strong degrees of heat are used, chemical operations are said to be performed in the dry way. The humid way is when fluids are used in the solution of bodies.

All the various parts of this science are found under their respective titles in the work, as ELEMENTS OF BODIES, GASES, METALS, &c.

CHERT, or CHURK, is the name given by the miners to a siliceous slate, which is massive, not disposed to pass into thin layers, but occurring in thick beds. Colour bluish, passing into yellowish gray. Fracture splintery; edges translucent; specific gravity 2.6363. Blocks of it are used in the porcelain manufactories in the midland counties for grinding flint-stones for the finer porcelain, and the purity of the rock augments the product of fine siliceous earth by its own attrition during the process. There is another sort called by the miners *White Chert*, which seems to be a transition of siliceous slate into quartz. It is not only used for grinding flints, but also as common millstone. A variety of chert has been found to answer as well as the best buhr stones of France in flour-mills, and is manufactured for that purpose. They may be had from 50 lb. to several hundred weight each.

CHESSE, a game performed with different pieces of wood, on a board divided into 64 squares or houses, in which chance has so small a share, that it is a matter of doubt whether a person ever lost but by his own fault. Each player has eight dignified pieces; namely, a king, a queen, two bishops, two knights, and two rooks, also eight pawns, all of which are of two different colours, or white and black. See AUTOMATON CHESS PLAYER.

CHESNUT TREE. Next to the oak, the Spanish chesnut timber is most coveted by carpenters and joiners. It likewise makes the best stakes, pallsadoes, vine-props, hop-poles, &c. and is also proper for mill-timber and waterworks. It is likewise fit for chests, tables, bedsteads, columns, &c. It was anciently very much used in the building of churches in this island, and must have been abundant, though now rare. The horse chesnut-tree is a very perishable wood.

CHILIAD, an assemblage of several things ranged by thousands. The term was particularly applied to tables of logarithms, which were at first divided into thousands.

CHILIEDRON, a solid figure of 1000 faces.

CHILIAGON, in Geometry, a regular plane figure of 1000 sides and angles.

CHIMES OF A CLOCK, a kind of periodical music produced at equal intervals of time, by means of a particular apparatus added to the clock

CHIMNEY. The rules for building chimneys are: 1. That no timber be laid within twelve inches of the foreside of the chimney jambs. 2. That all the joists on the back be laid with a trimmer. 3. That no timber be laid within the funnel of any chimney.

CHIVALRY, in Antiquity, an institution which, according to some writers, took its rise from the crusades; but, according to others, it gave occasion to that enterprise; and which, though founded in caprice, and productive of extravagance, had a very considerable influence in refining the manners of the European nations, during the twelfth, thirteenth, fourteenth, and fifteenth century. Chivalry was employed in rescuing humble and faithful vassals from the oppression of petty lords; their women from savage lust; and the hoary heads of hermits (a species of Eastern monks, much revered in the Holy Land,) from rapine and outrage. In the mean time, the courts of the feudal sovereigns became magnificent and polite; and, as the military constitution still subsisted, military merit was to be upheld; but destitute of its former objects, it naturally softened into fictitious images and courtly exercises of war, in "jousts" and "tournaments;" where the honour of the ladies supplied the place of zeal for the holy sepulchre: and thus the courtesy of elegant love, but of a wild and fanatic species, as being ingrafted on spiritual enthusiasm, came to mix itself with the other characters of the knights-errant, adding gentleness to valour.—This singular institution, in which valour, gallantry, and religion, were so strangely blended, was wonderfully adapted to the taste and genius of martial nobles; and its effects were soon visible in their manners. War was carried on with less ferocity, when humanity came to be deemed the ornament of knighthood no less than courage. More gentle and polished manners were introduced, when courtesy was recommended as the most amiable of knightly virtues. Violence and oppression decreased, when it was reckoned meritorious to check and to punish them. A scrupulous adherence to truth, with the most religious attention to fulfil every obligation, were its characteristics.

CHLORATES, combinations of the chloric acid with oxides, alkalis, &c.

CHLORIC ACID, is a combination of chlorine and oxygen, in greater abundance than in the oxide called enchlorine. By its combination with other substances, it forms the salts called chlorates, formerly denominated oxymuriates.

CHLORIDES, compounds of chlorine with various other substances.

CHLORINE, formerly supposed to be a compound of oxygen and the muriatic acid, was called by the French oxymuriatic acid gas, but Sir H. Davy having found it resisted the most powerful means used to decompose it, considered it a simple substance, and this is now the received opinion.

Mix in a mortar three parts of common salt, and one of black oxide of manganese. Introduce them into a glass retort, and add two parts of sulphuric acid. Gas will issue, which must be collected in the water-pneumatic trough. This gas is of a greenish yellow colour, easily recognized by daylight, but scarcely distinguishable by artificial light. Its odour and taste are disagreeable, strong, and so characteristic, that it is impossible to mistake it for any other gas. Its specific gravity is 2.4733. In its perfectly dry state, it has no effect on dry vegetable colours. With the aid of a little moisture, it bleaches them into a yellowish white. Scheele first remarked this property; Berthollet applied it to the art of bleaching in France, and from him Mr. Watt introduced it into Great Britain. If a lighted wax taper be immersed rapidly into this gas, it consumes very fast, with a dull reddish flame, and much smoke. The taper will not burn at the surface of the gas. Its taste is somewhat astringent, but not in the least degree acidulous. When we put in a perfectly dark place, at the ordinary temperature, a mixture of chlorine and hydrogen, it experiences no kind of alteration, even in a great many days. But if, at the same low temperature, we expose the mixture to the diffuse light of day, by degrees the two gases enter into chemical combination, and form muriatic acid gas.

Chlorine and Hydrogen, by their union form the muriatic acid, called also the hydrochloric acid. Some substances, when plunged into chlorine in an ignited state, are speedily

extinguished, while others, and those the least combustible of all substances, undergo spontaneous combustion. Several of the metals, and gold itself when plunged into it, burst into actual flame, and burn with great brilliancy.

**CHLORITES**, a kind of green jasper, almost as pellucid as the coarser emeralds. It is sometimes amorphous, and sometimes crystallized. There are four species, viz. the earthy chlorite, common chlorite, the foliated, and schistose chlorite.

**CHOCOLATE**, a sort of cake made chiefly from the cocoa-nut. When the cocoa is properly roasted and cleansed, it is pounded in a mortar, and afterwards ground on a stone. It is then put hot into tin moulds, in which it soon congeals. The Spaniards mix with the cocoa-nuts, cloves, cinnamon, and other ingredients; but in England, the chocolate is made of simple cocoa, with a little sugar and vanilla.

**CHOLERA MORBUS**, a sudden effusion or overflowing of the bile on the stomach or intestines; and its symptoms are, violent retching, and in some cases, purging.

**CHOLESTERIC ACID**, is obtained from cholestine by heating it with strong nitric acid.

**CHOLESTERINE**, the name given to the pearly substance of human biliary calculi.

**CHORD**, in Geometry, is the right line joining the extremities of any arc of a circle; such are the lines A B, D C.—1. A line drawn from the centre to bisect a chord, is perpendicular to the chord; or if it be perpendicular to the chord, it bisects both the chord and the arc of the chord, as O E, O E. 2. Chords which are equally distant from the centre of a circle, are equal to each other; or if they are equal to each other, they are equally distant from the centre. 3. The chord of an arc is a mean proportional between the diameter and versed sine of that arc.

*Line of CHORDS.* See **PLANE SCALE AND SECTOR**.

**CHORD**, or *Cord*, in Music, denotes the string or line, from the vibration of which the sensation of sound is excited; and by whose divisions the several degrees of time are determined.

**CHOROGRAPHY**, the act of making a map of a particular country or province.

**CHORUS**, in Music, is when, at certain periods of a song, the whole company are to join the singer in repeating certain couplets or verses.

**CHROMATICS**, that part of the science of optics by which the properties of the colours of light, and of natural bodies, are illustrated and explained.

**CHROMIC ACID** has been obtained from red oxide of lead, ore of Siberia, and from an ore of iron from the department of Var in France. It has the property of colouring its salts, and hence it has been called chromic. If two parts of the red lead ore of Siberia, in fine powder, be boiled with one of an alkali saturated with carbonic acid, in forty parts of water, a carbonate of lead will be precipitated, and the chromate remain dissolved. The solutions are of a lemon colour, and afford crystals of a somewhat deeper hue. Those of chromate of ammonia are in yellow laminae, having the metallic lustre of gold. The chromate of barytes is very little soluble, and that of lime still less. They are both of a pale yellow, and when heated give out oxygen gas, as do the alkaline chromates.

**CHROMIUM**, a very rare metal, found either in the form of chromate of lead, or of chromate of iron. The emerald of Peru, and spinel ruby, owe their colours to this metal. Chromium is obtained from its native combinations by decomposing them by the alkaline carbonates, precipitating the chromic acid, and heating it strongly in a crucible. Chromium is a porous mass of agglutinate grains, brittle, of a white between tin and steel. Specific gravity 5.9. It is susceptible of a small degree of magnetism. It resists all the acids, except the nitromuriatic.

**CHRONOLOGY**, is that science which treats of time, and shews its different measures or computations, as they have been observed by different nations. By chronology we are enabled truly to date the beginning and end of the reigns of princes, the births and deaths of eminent persons, the revo-

lutions of empires and kingdoms, battles, sieges, or any other remarkable events. Without this useful science, that is to say, without distinguishing the times of events as clearly as the nature of the case will admit, history would be little better than a *heap* of confusion, destitute of light, order, or beauty. See **TIME**, **YEAR**, **ÆRAS**, &c.

**CHRONOMETER**, in general, means an instrument used in measuring time, as dials, clocks, watches, &c. The term, however, is commonly used for a machine so contrived as to measure a small portion of time with great exactness, even to the sixteenth part of a second, and which is of great use in astronomical observations, ascertaining the time of the fall of bodies, the velocity of running waters, &c. The lamp chronometer consists of a chamber lamp, or a cylindrical vessel about three inches high, and one inch diameter. To the stand is fixed a handle, which supports a frame, covered with oiled paper, about 12 inches high, and 4 wide. This frame is divided into 12 equal parts by horizontal lines, at the ends of which are marked the hours, and between the lines are diagonals divided into halves, quarters, &c. On the handle, and next to the glass, is fixed a stile, and as the distance of this stile from the flame of the lamp is only half an inch, if the distance of the frame from the stile be 6 inches, then while the float containing the light descends by the decrease of the oil, one inch, the shadow of the stile on the frame will ascend 12 inches, and thus shew, by its progression, the increase of the hours with the several divisions. The oil must be very pure, and the wick of the same size and substance.

**CHRYSA LIS**, or **AURELIA**, in Natural History, denotes the state of seeming insensibility, in which butterflies, moths, and some other insects, pass through before they arrive at their winged or perfect state. The figure of the chrysalis is generally conical; and the creature, when in this state, seems to have neither legs, wings, nor motion. It is almost destitute of life, for it takes no nourishment, nor has it apparently any organs for the purpose. The external covering of the chrysalis is membranous, smooth, and glossy, but some of them have hairs; and others are rough all over like shagreen. They are divided generally into two classes, the round and the angular, and of these again there are several subordinate distinctions. Some of them are very beautiful. The time of the animal in the chrysalis state varies in different species, some being no more than eight days, while others are as many months.

**CHRY SOLITE**, in Natural History, a gem to which the ancients gave the name of topaz; their true chrysolite being that which modern jewellers call topaz. The chrysolite is found in angular fragments and crystallized. It is of a green colour, and there are two varieties, 1. the common chrysolite, found in Ceylon, South America, and Bohemia: its colour is a yellowish green. 2. Olive chrysolite, is found commonly in basalt, and is of an olive-green colour.

**CHRY SOPRASE**, a mineral found in Germany, and which is always amorphous. It is of a green colour, and splintery.—Also, a variety of chalcedony used in jewellery. It consists of 90 silica in the 100.

**CHRY SOPRASUS**, in Christian Antiquity, the tenth of those precious stones which adorned the foundation of the heavenly Jerusalem: the colour of it was green, inclining to that of gold, as its name imports. See **Revelation**, chap. xxi. 20.

**CHURCHWARDENS**, the guardians or keepers of the church, are persons annually chosen in Easter week, by the joint consent of the minister and parishioners—or according to the custom of the respective places—to look after the church and churchyard, and things thereunto belonging. They are intrusted with the care and management of the goods and personal property of the church, which they are to order for the best advantage of the parishioners; but they have no interest in, or power over, the freehold of the church itself, or of any land or other real property belonging to it: these are the property of the parson or vicar, who alone is interested in their loss or preservation. The churchwardens, therefore, may purchase goods and other articles for the use of the parish; they may, likewise, with the assent of the parishioners, sell or otherwise dispose of the goods of the church; but without such consent, they are not authorized to alienate any of the property under their care.

All peers of the realm, clergymen, counsellors, attorneys, clerks in court, physicians, surgeons, and apothecaries, are exempt from serving the office of churchwarden, as is every licensed dissenting teacher.

**CHURN**, an implement for agitating cream or milk, so as to separate the butyrous particles from the serous, and to effect the production of butter.

The inferiority of the churns in common use has induced several ingenious mechanics to exert their skill in contriving others that would render the process of making butter less tedious and expensive. Of these, one of the most valuable is Bowler's improved churn, with which the Society for the Encouragement of Arts, &c. were so well satisfied as to present the inventor with thirty guineas. This churn renders the operation of making butter far less fatiguing; and it has, besides, some peculiar advantages, which will appear in our description.

This churn is of the barrel kind, being a cylinder 18 inches in diameter, and 9 wide; the sides are of wood, and the rim a tin plate, which has two openings, one  $8\frac{1}{2}$  inches in length, and 4 in width, through which the cream is poured into the churn, and the hand introduced for cleaning it; the other a short pipe, one inch in diameter, by which the buttermilk runs out of the churn when the operation is finished. The first of these openings has a wooden cover, fastened down by two screws; and the other a cork fitted to it, while the butter is churning. There is further, near the larger opening, a small vent-hole with a peg, to admit the passage of any air that may be discharged from the cream at the beginning of the operation. An axle also through the churn, terminating in two gudgeons, on which it passes, hangs; its lower part being immersed in a trough, in order to hold occasionally either hot or cold water, according to the season of the year. On the inside of the rim are four projecting pieces of wood, with holes, serving to agitate the cream by the motion of the churn. The movement is caused by a pendulum 3 feet 6 inches long, that has an iron bob weighing 10 lbs. and at its upper end a turning pulley 10 inches in diameter, from which a rope goes twice round another pulley about 3 inches in diameter, fixed on the axis of the churn, which it causes to make a partial revolution by each vibration of the pendulum.

There are likewise sliding covers to the machinery, and another to the water trough; in order, when hot water is used, to secure the steam, and keep the cream in a proper degree of warmth. The motion of the pendulum is given, and continued, by means of a wooden rod about 3 feet 9 inches in length, which turns on a pin 3 inches above the bob of the pendulum. If there be a transverse handle at the upper end of this wooden rod, a boy may give motion to the churn with great facility,

even while sitting; the action being then much like that of rowing, one of the most advantageous methods of applying human force.

In the figure, AA is the body. B, an opening by which the cream is put in. C, the cover of the large opening: the small hole on the opposite side of the churn cannot be shewn in this view. D, the gudgeon on which the body of the churn hangs. E, the upper or larger pulley. F, the smaller pulley fixed on the axis or gudgeon of the churn. G G, the rod of the pendulum hanging from the upper pulley E. H, the bob of the pendulum. I I, the handle, moveable on a pin at a, by which the pendulum is moved to and fro, making a traverse in form of the dotted line K K. L, the trough for the hot or cold water. M, a projecting piece of wood, with a shoulder, by which the handle I is supported, when the churn is not at work.

**CHYLE** and **CHYME**. See **BLOOD**. When food has been received into the stomachs of animals, by the action of the saliva and a juice in the stomach called the gastric juice, it is converted into a milky fluid called chyme. This fluid afterwards passes into the intestines, where it unites with the pancreatic juice and bile, and is there separated into chyle, or into feculent matter, which is carried on and discharged. Chyle is taken up by the lacteal absorbent vessels, and finds its way into the blood, which is circulated over the whole system, and supplies its constant waste.

**CICATRIX**, in Surgery, a little seam or elevation of callous flesh rising on the skin after the healing of a wound or ulcer. It is commonly called a scar.

**CICORIUM**, **Succory**, a genus of the polygamia æqualis order, in the syngenesia class of plants; belonging to the 49th natural order, compositæ. There are three species, 1. *Cichorium endivia*, the common endive, which is both an annual and biennial plant, and esteemed as a salad. 2. *Cichorium intibus*, or wild succory, grows naturally by the side of roads, and in shady lanes. It is good in scorbutic complaints. 3. *Cichorium spinosum*, with a prickly stalk, grows in Sicily, and the islands of the Archipelago.

**CIDER**, a drink made of the juice of apples. In this process the Devonshire method is preferred, which is, to gather all the apples that have dropped from the trees, from time to time, into a heap, where they are suffered to lie about ten days; secondly, such as are to be gathered from the trees, having acquired some degree of maturity, are laid in a heap by themselves for about a fortnight; and lastly, the hard fruit which are to be left on the trees till frost is apprehended, are laid in separate heaps for a month or six weeks. These heaps are to be made in an open part of the orchard, without any regard to the weather. After having lain the proper time, the apples are ground in a mill resembling that for grinding bark, and the pumice received in a large open vessel, capable of containing as much as is sufficient for one making, or cheese as it is termed. This pumice should remain no longer in the vat than till there is enough broken for one pressing. The stooming or stumming of cider is done by burning a match in a clean hogshead, moist from recent rinsing, and racking the cider on the fret into it. If much on the fret, when the cider is half racked into the scented cask, burn another match in each cask, rolling the same well about for a couple of hours. Stum is the rich must of good cider, blended with the vapour of the burning match, which prevents its fermenting; and when disposed to fret, must be racked into another cask, well matched. Stum is used to mend declining cider, to make it ferment afresh, and give to it new life and sweetness. Boiled cider makes the best stum for keeping.

**CIDER Wine**.—The method of preparing this liquor in America, where it is much used, is as follows: the fresh apple juice is evaporated in a brewing copper till half of it be wasted; the remainder is then put into a wooden cooler, and afterwards into a cask, with an addition of yeast, and so fermented in the ordinary way. This process has lately been adopted in some of our cider counties; but from the impregnation of the copper in the liquor, the public ought to be guarded against the use of it.

**CIMEX**, or **Bug**, a genus of hemipterous insects, of which there are above 121 species. The larvæ of bugs only differ from the perfect insect by the want of wings; they run over plants, and change to chrysalies without undergoing any

material change. The *cimex lectolarius*, or house-bug, is acceptable to spiders, and even sought after by the wood-bug. Various methods have been recommended for destroying this pernicious insect, as oil of turpentine, camphor, &c. One of the best methods for extirpating these insects from bedsteads, is by thoroughly washing all the parts where they are likely to lodge, with a solution of corrosive sublimate. Great caution should be had in the use of this mixture, as it is one of the most deadly poisons known.

**CIMOLIA ALBA**, the earth of which tobacco pipes are made. It is dense, compact, heavy, of a dull colour, and of a very close texture. It is found in the Isle of Wight, Dorsetshire, Devonshire, and Staffordshire. **CIMOLIA NIGRA**, is of a dark lead colour, hard, dry, and heavy. It burns perfectly white, and is found in Northamptonshire, where it is used for making pipes.

**CINCTURE**, or **CEINCTURE**, in Architecture, a ring or list at the top and bottom of the shaft of a column.

**CINNABAR**, in Natural History, is either native or factitious. The native is an ore of quicksilver moderately compact, very heavy, and of a striated colour. *Factitious* cinnabar, is a mixture of mercury and sulphur sublimated, and reduced to a fine red substance. The principal use of it is in painting, when it passes under the name of vermilion. In medicine, it is recommended as a sedative and antispasmodic; also as a mercurial fumigation in venereal cases.

**CINNAMON**, the bark of two species of *laurus*. The true sort is from the *laurus cinnamomum*, and the base kind from the *laurus cassia*. Cinnamon is an astringent in the *primæ viæ*, but in the remoter seats of action it is an aperient and an alexipharmic. It is useful in diarrhoeas and flatulencies. The oil of cinnamon is made now in England, and is much better than what was formerly imported from Holland. Cinnamon water is made by distilling the bark first infused in spirit of wine or brandy.

**CINQUE PORTS**, five havens that lie on the east part of England, towards France, which have a particular policy, and are governed by a keeper, with the title of the lord warden of the Cinque Ports, which office belongs to the constable of Dover; and their representatives are called Barons of the Cinque Ports. These five ports are, Dover, Hastings, Romney, Hythe, and Sandwich; to which Winchelsea and Rye have been since added.

**CIPHER**, or **CYPHER**, one of the Arabic characters used in arithmetic. It is also a kind of conjunctive character, consisting of letters interwoven: these are generally the initials of a person's name. Cipher also denotes certain secret characters disguised and varied, used in writing letters for the purpose of secrecy. The properties necessary in this kind of writing are, that the cipher be easy to read by the person for whom it is intended, and clear of suspicion by any stranger into whose hands the same may fall.

**CIRCINUS**, the *Compasses*, is a small constellation south-east of Centaurus, containing only four stars, and one only of these measures the 4th magnitude.

**CIRCLE**, a plane figure continued by one line, which is called the circumference, and is such that all straight lines, drawn from a certain point within the figure, to the circumference, are equal to one another, and this point is called the centre of the circle. The diameter passes through the centre, as *AB*; and a radius is one-half a diameter, as *DC*, or *DB*. The third book of Euclid's Geometry contains the theory of the circle, and the 4th book many practical problems of and belonging to the circle.

1. To find the centre of a circle. Draw any right line *AB* within the circle; bisect this line in *K*, and through the point *K* draw *CD* perpendicular, or at right angles, to *AB*, and bisect *CD* in *E*; the point *E* is the centre of the circle.

2. To describe a circle through three given points, *A*, *B*, *C*. Join the points

19.

*AB*, *BC*; bisect *AB*, *BC*, in the points *D* and *E* by the perpendiculars *DO*, *EO*; and the point of intersection *O* will be the centre, and *OA*, or *OB*, or *OC*, the radius required.

3. To divide a given circle into any number of co-centric parts, equal to each other. Draw the radius *AB*, and on it describe the semicircle *AedB*. Divide *AB* into the proposed number of equal parts 1, 2, &c. and erect the perpendiculars 1*d*, 2*e*, &c. meeting the semicircle in *d*, *e*, &c. From the centre *B*, and radii *Bd*, *Be*, &c. describe circles; so shall the circle be divided into the proposed number of equal co-centric parts.

4. To divide a circle into any number of parts, equal both in area and periphery, as in the following figure. Divide the diameter *AB* into the proposed number of equal parts at the points *S*, *T*, *V*, &c.; then on one side of the diameter describe the semicircles on the diameters *AS*, *AT*, *AV*; and on the other side of the diameters *BV*, *BT*, *BS*; so shall the parts 1, 7, 3, 5, 5, 3, 7, 1, be all equal, both in area and periphery.

**Quadrature and Rectification of the Circle.**—This is a problem, which, of all others, has most engaged the attention of mathematicians, at least amongst the ancients; for being the most regular and best known of any curvilinear figure, it soon became a question to determine its area; and as no reason could be seen why this should not be found, the greater part of the ancients seem to have attempted the solution of it, as have likewise several of the moderns. In the present day, however, though the problem has not been demonstrated to be absolutely impossible, yet few trials are now made, and the solution is given up as hopeless. But though neither the rectification nor quadrature of the circle has been completely determined, yet approximations to them have been found, and some of these to such a degree of accuracy, that in a circle whose diameter is equal to that of the orbit of Saturn, we should not, in assigning its circumference, differ from the truth, in the breadth of a single hair.

We cannot, in the present article, enter into investigations of the several approximating rules that have been given for finding the circumference and area of a circle; and in the present instance, we must content ourselves with merely stating the several results, without entering at all into the methods made use of in determining them.

The simplest and most ancient approximation is as follows: As 7 to 22, so is the diameter to the circumference. This is the ratio given by Archimedes. Other approximations, nearer than the above, but in larger numbers, are as follows: *viz.*

|    |             |                                        |
|----|-------------|----------------------------------------|
| as | 106 : 333   | } so is diameter to the circumference, |
|    | 113 : 355   |                                        |
|    | 1702 : 5347 |                                        |
|    | 1815 : 5702 |                                        |

which are each more accurate than the preceding one.

**CIRCLE of Curvature**, in Geometry, that circle, the curvature of which is equal to that of any curve at a certain point. It is also called the circle of equi-curvature.

**CIRCLES of the Sphere**, such as cut the mundane sphere, and have their circumference in its surface. They are either moveable or fixed. The first, are those whose peripheries are in the moveable surface, and which therefore revolve with its diurnal motion; as the meridians, &c. The latter, having their periphery in the immoveable surface, do not revolve; as the ecliptic, equator, and its parallels, &c. The circles of the sphere are either great or little. A great Circle of the sphere, is that which divides it into two equal parts or hemispheres, having the same centre and diameter with it; as the horizon, meridian, &c. A little, or less Circle of the sphere, divides the sphere into two unequal parts, having neither the same centre nor diameter with the sphere; its diameter being only some

2 x

chord of the sphere less than its axis, such as the parallels of latitude, &c.

CIRCLES of *Declination*, are great circles intersecting each other in the poles of the world.

*Diurnal* CIRCLES, are parallels to the equinoctial, supposed to be described by the stars, and other points of the heavens, in their apparent diurnal rotation about the earth. It may here be observed, that most circles of the sphere are transferred from the heavens to the earth; and have thus a place in geography, as well as in astronomy; all the points of each circle being conceived as let fall perpendicularly on the surface of the terrestrial globe, and hence tracing out circles perfectly similar to them. Thus the terrestrial equator is a circle conceived precisely under the equinoctial line, which is in the heavens: and so of the rest.

CIRCLES of *Excursion*, are circles parallel to the ecliptic, and at such a distance from it, as that the excursions of the planets towards the poles of the ecliptic may be included within them; usually fixed at ten degrees.

CIRCLES, *Horary*, in Dialing, are the lines which shew the hours on dials; though these be not drawn circular, but nearly straight. CIRCLE, *horary*, on the Globe, a brazen circle fixed to the north pole, and furnished with an index, shewing the difference of meridians, and serving for the solution of many problems. On globes of late structure, this circle is often placed on the equator, and the index is made to slide on a brass wire running parallel to the equator, and above it.

CIRCLE of *Illumination*, a circle passing through the centre of the earth or moon, perpendicular to a line drawn from the sun to the respective body. This is supposed to separate the illuminated part of the globe from the darkened part; which it does very nearly.

CIRCLES of *Latitude*, or *Secondaries* of the *Ecliptic*, are great circles perpendicular to the plane of the ecliptic, passing through the poles thereof, and through every star and planet. They are so called, because they serve to measure the latitude of the stars, which is nothing but an arch of one of these circles intercepted between the star and the ecliptic.

CIRCLES of *Longitude*, are several less circles, parallel to the ecliptic; still diminishing, in proportion as they recede from it. On the arches of these circles the longitude of the stars is reckoned.

CIRCLE of *perpetual Apparition*, one of the less circles, parallel to the equator; described by any point of the sphere touching the northern point of the horizon; and carried about with the diurnal motion. All the stars included within this circle never set, but are ever visible above the horizon.

CIRCLE of *perpetual Occultation*, is another circle at a like distance from the equator; and contains all those stars which never appear in our hemisphere. The stars situated between these circles alternately rise and set at certain times.

*Polar* CIRCLES, are immoveable circles, parallel to the equator, and at a distance from the poles equal to the greatest declination of the ecliptic.

CIRCLES, *Druidical*, a name given to certain ancient enclosures, formed by rude stones circularly arranged. These, it is supposed, were temples, or places for solemn assemblies, for councils, or seats of judgment.

CIRCUIT, in Law, a longer course of proceedings than is needful to recover the thing sought for. Circuit also signifies the journey or progress, which the judges take twice every year, through the several counties of England and Wales, to hold courts and administer justice, where recourse cannot be had to the King's courts at Westminster; hence England is divided into six circuits, viz. the Home circuit, Norfolk circuit, Midland circuit, Oxford circuit, Western circuit, and Northern circuit. In Wales, there are but two circuits, North and South Wales. Two judges are assigned by the king's commission to every circuit. In Scotland there are three circuits, viz. the Southern, Western, and Northern, which are likewise made twice every year, viz. in spring and autumn.

CIRCULAR, any thing relating to the circle; as CIRCULAR *Arcs*, *Instruments*, *Lines*, *Parts*, *Ring*, &c.

CIRCULAR *Ring*, is the measure or space included between two concentric circles, and the area of it is consequently equal to the difference of the areas of the two circles. Or the area

may be found thus: Multiply the sum of the two diameters by the difference of them, and that product again by .7854, which will give the area required.

CIRCULAR *Sailing*, the method of moving a ship upon a great circle of the globe.

CIRCULAR *Numbers*, a name sometimes applied to numbers whose powers terminate in the same digits as their roots; an old and useless distinction.

CIRCULAR *Parts* (Napier's), are five parts of a right-angled, or a quadrantal spherical triangle; they are the legs, the complement of the hypotenuse, and the complements of the two oblique angles.

CIRCULAR *Instruments*, or *Reflecting* or *Multiplying Circles*, are instruments which possess all the advantages of accuracy attending large instruments, in diminishing the errors of division and eccentricity at pleasure, by means of reflection, though the instruments themselves are small and portable. Circular instruments may be considered as improvements of Hadley's octant, and the marine sextant, which are for the same purpose; viz. for observing the altitudes, distances, &c. of the heavenly bodies, extremely useful for navigators in finding the moon's distance, and other nautical purposes.

CIRCULATING DECIMALS, or *Recurring Decimals*, are those that consist of a repetition of a small number of digits, as .646464, &c. .4127127127, &c.; in fact, every decimal that is not finite, is a circulating decimal, or is such, that if continued far enough the same figures will again recur; but it is only those, of which the periods of circulation consist of a few figures, that receive generally the definition of circulating decimals.

When the circulation consists of the same digit repeated, it is called a *Simple Circulate*, and is distinguished by a point

placed over it: thus .111, &c. = .1; .333 = .3, &c. When the period of circulation consists of more than one digit, it is called a *Compound Circulate*, and is distinguished thus,

.234234234, &c. = .234. A *Mixed Circulate* is that which has other figures in it that are not repeated, as .7848484, &c.; and

these are represented thus, .784.

All operations, as multiplication, division, &c. of these numbers, may be performed by the same rules as common decimals; and in fact, there are very few cases in which those rules are not to be preferred, though some authors, as Brown, Cunn, Malcolm, Emerson, Donn, and particularly Henry Clarke, have treated at considerable length the theory of circulating decimals; as also Dr. Wallis, who seems to have been the first author that distinguished them under a separate head.

*Reduction of Circulating Decimals.—Case 1.* To reduce a Simple or Compound Circulate to its equivalent Fraction.—*Rule.* Take the figures in the given decimal, considered as a whole number, for the numerator; and as many 9's as there are places in the circulate for the denominator; observing only, that when there are any integral figures in the circulate, as many ciphers must be annexed to the numerator, as the highest place in the repetend is distant from the decimal point thus,

|                |    |               |                                            |
|----------------|----|---------------|--------------------------------------------|
| Examples. .... | 1. | The circulate | .6 = $\frac{6}{9} = \frac{2}{3}$           |
|                | 2. | .....         | .36 = $\frac{36}{99} = \frac{4}{11}$       |
|                | 3. | .....         | .09 = $\frac{9}{99} = \frac{1}{11}$        |
|                | 4. | .....         | 2.063 = $2\frac{63}{999} = 2\frac{7}{111}$ |

*Case 2.* To reduce a Mixed Circulate to its equivalent Fraction.—*Rule.* Subtract the finite part of the expression, considered as a whole number, from the whole mixed repetend, taken in the same manner for the numerator; and to as many 9's as there are repeating places in the circulate, annex as many ciphers as there are finite decimal places for a denominator; thus,

|              |               |                                                                       |
|--------------|---------------|-----------------------------------------------------------------------|
| Examples.—1. | The circulate | 138 = $\frac{138 - 13}{900} = \frac{125}{900} = \frac{5}{36}$         |
| 2.           | Again ....    | 2.418 = $2\frac{418 - 24}{990} = 2\frac{394}{990} = 2\frac{197}{495}$ |

And so on in other examples. Having thus shewn how to reduce

any circulate, simple, compound, or mixed, to its equivalent fraction; all the rules of addition, subtraction, multiplication, division, &c. of circulating decimals, may be performed by the rules that are given for the same operations in fractions; which see under their respective heads.

**CIRCULATION OF THE BLOOD**, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart to all parts of the body by the arteries, and returned from the same parts to the heart by the veins.

**CIRCULUS**, a chemical instrument, consisting of an iron ring, which being heated red-hot, is applied to the necks of glass vessels to make the necks come evenly off.

**CIRCUMFERENCE**, **CIRCUMFERENTIA**, in a general sense, denotes the line or lines bounding any figure; but it is commonly used, in a more limited sense, to denote the periphery of a circle, which is every where equally distant from a certain point within, called the centre. See **CIRCLE**.

**CIRCUMFERENTOR**, an instrument used by surveyors in taking angles; it consists of a brass circle and index, in one piece, commonly about seven inches in diameter, an index about fourteen inches long, and one and a half inches broad. On the circle is a card or compass, divided into 360 degrees; the meridian line of which answers to the middle of the breadth of the index. There is also soldered on the circumference a brass ring, on which screws another ring with a flat glass in it, so as to form a kind of box for the needle, suspended on the needle in the centre of the circle. There are also two sights to screw on, and slide up and down the index, as also a ball and socket screwed on the under side of the circle, to receive the leg of the three-legged staff.

The above description answers to the most simple form of the circumferentor; but an improved instrument of this kind is sold by Jones, of Holborn, which in some measure answers the purpose of a theodolite.

**CIRCUMGYRATION**, the whirling motion of a body about a centre.

**CIRCUM-POLAR Stars**, are those situated near the north pole of the heavens, or those which revolve about it without setting.

**CIRCUMSCRIBED FIGURE**, is that which is circumscribed or drawn about another figure, so as to touch it on every side.

A right-lined figure is said to be circumscribed about another, when all the angles of the latter fall in the sides of the former. A right-lined figure circumscribes a curvilinear one, when the periphery of the latter touches all the sides of the former. A circle, or other curvilinear figure, circumscribes a right-lined one, when all the angles of the latter are in the periphery of the former.

**CIRCUMSCRIBED Hyperbola**, one of Newton's hyperbolas, of the second order, which cuts its asymptotes, and contains the part cut off within itself.

**CIRCUMVALLATION**, in military affairs, is a fortification of earth, consisting of a parapet and trench made round a town intended to be besieged, when opposed to any army that may come to its relief.

**CIRRI**, in botanical language, denotes the fine strings or filaments by which creeping plants adhere to walls and trees. In ichthyology, the term is applied to appendages hanging from the mouths of fishes, and called by some, beards.

**CISSOID OF DIOCLES**, in the higher Geometry, is a curve line of the second order, invented by Diocles, an ancient Greek geometrician, for the purpose of finding two continued mean proportionals between two other given lines. The generation of this curve is as follows: At the extremity B of the diameter AB of the circle AOB, draw perpendicular to it the indefinite line CBD, to which from the other extremity A draw several lines cutting the circle in I, O, N, &c. and upon these lines set off the corresponding equal distances, viz. HM = AI, FO = AO, CL = AN, &c.; then the curve line drawn through all the points M, O, L, &c. is the cissoid. Other

methods of constructing this curve may be seen in Newton's "Universal Arithmetic," and Emerson on "Curve Lines."

**CISTERN**, on board of ships, is a large wooden trough, placed in the well just below the orlop, and having a leaden pipe, which goes through the ship's side, whereby it is occasionally filled with sea water, which is thence pumped up to wash the decks, &c.

**CISTUS**, the *Rock Rose*, a genus of the monogynia order, in the polyandria class of plants, ranking in the natural method under the 20th order, rotaceæ. There are 66 species, mostly natives of the southern parts of Europe. They are very beautiful evergreen shrubs, and very ornamental in gardens. The flowers are white, purple, and yellow; they are propagated by seeds or cuttings. Gum labdanum is obtained from the species in the Levant.

**CITADEL**, a place fortified with four, five, or six bastions, on a convenient hill, near a city which it commands.

**CITATION**, in ecclesiastical courts, is the same with a summons in the civil.

**CITRUS**, the citron, orange, and lemon tree, a genus of the polyadelphia class, and icosandria order of plants. Calyx quinquefid; petals oblong, and five; antheræ twenty, filaments unite into various bodies; fruit nine-celled. There are five species, and many varieties. 1. *Citrus aurantium*, the orange, of which the varieties are, the Seville orange, a handsome tree, and the hardiest of any. The fruit is large, rough-rinded and sour. 2. The China orange, which has a smooth, thin rind, and sweet fruit. 3. The forbidden fruit-tree, very much resembles the common orange-tree, but the fruit is large; the flavour is delicious. 4. The horned orange, is a tree of moderate size, producing fruit which divide, and the rind has divisions like horns. 5. The hermaphrodite orange produces fruit formed partly like that of the orange, and partly like a citron. 6. The dwarf orange tree, or nutmeg orange, grows to the height of two or three feet, and the fruit is very small. II. *Citron medica*, the citron tree, of which there are six varieties. The lemon tree is accounted a variety of the citron, and of this there are not less than eleven sorts. Besides these varieties or the citrus there are several others, as, 1. The citrus trifoliata, a thorny shrub, which grows in Japan. 2. *Citrus decumana*, of shaddock, which is a native of the East and West Indies. 3. *Citrus Japonica*, the fruit of which is about the size of a cherry, and very pleasant to the taste.

**CIVET**, is collected betwixt the anus and the organs of generation of a fierce carnivorous quadruped, met with in China, and the East and West Indies, called a civet cat; but bearing a greater resemblance to a fox or marten than a cat: it is a species of *Viverra*. Several of these animals have been brought into Holland, and afford a considerable branch of commerce, particularly at Amsterdam. The civet is squeezed out in summer every other day; in winter twice a week: the quantity procured at once, is from two scruples to a drachm, or more. The juice thus collected is much purer and finer than that which the animal sheds against shrubs or stones in its native climates. Good civet is of a clear yellowish or brownish colour, not fluid, nor hard, but about the consistence of butter or honey, and uniform throughout; of a very strong smell; quite offensive, when undiluted; but agreeable, when only a small portion is mixed with other substances.

**CIVIL DAY**, like the astronomical or natural, consists of twenty-four hours, but begins differently in different nations. The ancient Babylonians, Persians, Syrians, and most of the eastern nations, began their day at sun-rising. The ancient Athenians, the Jews, &c. began their day at sun-setting, which custom is followed by the modern Austrians, Bohemians, Silesians, Italians, Chinese, &c. The Arabians begin their day at noon, like the modern astronomers. The ancient Egyptians, Romans, &c. began their day at midnight, and this method is followed by the English, French, Germans, Dutch, Spanish, and Portuguese.

**CIVILIAN**, a term applied to the doctors and professors of the civil law. In London they have a college, called Doctors' Commons.

**CIVIL LAW**, is properly the peculiar law of a state, country, or city, but is now applied exclusively to a body of laws compiled out of the best Roman and Grecian systems of

jurisprudence, agreeable to what is denominated the law of nature and nations, and which were generally observed throughout the Roman dominions above 1200 years. In our country, the civil law is used in the ecclesiastical courts and the admiralty, but is subservient to the common law.

**CIVIL YEAR.** See **YEAR**.

**CLAMPS**, in Naval Architecture, thick planks on the inner part of a ship's side, used to sustain the ends of the beams, and extending from stem to stern, including the whole interior range of the side. They are placed close under each deck, so as to be securely fayed to all the timbers, to which they are fastened by nails through the clamp, and penetrating two-thirds of the thickness of the timbers.

The clamps of the lower and second decks ought to be equal in thickness to half the corresponding timbers in that part, and as broad as can be procured. In their disposition it is essentially necessary to avoid their being wounded by the ports, as the strength and firmness of a ship greatly depend on the substance and solidity of those pieces which lie horizontally in her frame.

**CLAMPS** are also smooth crooked plates of iron fore-locked upon the trunnions of the cannon, to keep them fast upon their carriages: these, however, are more properly termed cap-squares. Clamps of the latter kind are likewise frequently used to fasten the masts or bowsprits of small vessels, and of boats.

**CLAN**, a term used in Scotland to denote a number of families of the same name, under a feudal chief, who protected them, and in return for that protection commanded their services as his followers, and led them to war, and on military excursions.

**CLARENCIEUX**, the second king at arms, so called from Lionel Duke of Clarence, to whom the title originally appertained. His office is to marshal the order of procession in the funerals of the inferior nobility, &c.

**CLARIFICATION**, in Chemistry, the clearing and fining any fluid from heterogeneous matter.

**CLARO OBSCURO**, in Painting, the art of distributing advantageously the light and shadow of a piece with regard to the ease of the eye, and the effect of the whole. It also denotes a design consisting of only two colours, usually black and white, or black and yellow.

**CLASS**, a term given to the general divisions of a subject: thus in the Linnæan system, animals and plants are divided into classes.

**CLAY**, a kind of earth, which was formerly denominated argillaceous, but is now found to be a mixture of alumina and silica in various proportions. Clay also contains carbonate of lime, of magnesia, barytes, oxide of iron, &c. It adheres slightly to the tongue; feels greasy; and falls to powder in water. When pure, it is white with a tinge of blue or yellow. Potters' clay stains the fingers, and acquires a polish by rubbing. When properly moistened, it is very ductile. Tobacco pipe clay is a variety of this species. The structure of schistose clay is slaty, and of a gray colour. It is usually found in coal mines.

**CLAY SLATE**, is a mineral extensively distributed, forming part of primitive and transitive mountains. Its constituents are 48.6 silica, 23.5 alumina, 1.6 magnesia, 11.3 peroxide of iron, 0.5 oxide of manganese, 4.7 potash, 6.3 carbon, 0.1 sulphur, and 7.6 water and volatile matter.

**CLEATS**, pieces of wood of different shapes, used occasionally in a ship, to fasten ropes upon: some have one, and some two arms; others are without arms, being hollowed in the middle to tie any thing to, and are called belaying cleats, a deck cleat, and a thumb cleat.

**CLEF**, or **CLIFF**, in Music, a mark set at the beginning of a song, denoting the key in which the same is to be performed, or it is a letter marked on a line, to explain the rest.

**CLEOSTRATUS**, a celebrated astronomer, born in Tenedos, was, according to Pliny, the first who proposed the signs of the zodiac; others say, that he only invented the signs Aries and Sagittarius. He also corrected the errors of the Grecian year, about the 306th before Christ.

**CLEPSYDRA**, an instrument or machine serving to measure time by the fall of a certain quantity of water, though there

have likewise been clepsydræ made with mercury. The Egyptians, by this machine, measured the course of the sun. Tycho Brahe, in later days, made use of it to measure the motion of the stars, &c.; and Dudley used the same contrivance in making all his maritime observations. The use of clepsydræ is very ancient; they were invented in Egypt, under the Ptolemies; as were also sun-dials. Their use was chiefly in the winter, as the sun-dials served in the summer: but they had two great defects; the one, that the water ran out with a greater or less facility, as the air was more or less dense; the other, that the water ran more readily at the beginning than towards the conclusion.

*The Construction of a common Clepsydra.*—To divide any cylindrical vessel into parts, to be emptied in each division of time; the time wherein the whole, and that wherein any part is to be evacuated, being given: Suppose a cylindrical vessel, whose charge of water flows out in twelve hours, were required to be divided into two parts, to be evacuated each hour. 1. As the part of time 1 is to the whole time 12, so is the same time 12 to a fourth proportional 144. 2. Divide the altitude of the vessel into 144 equal parts: here the last will fall to the last hour; the three next above to the last part but one; the five next to the tenth hour; lastly, the twenty-three last to the first hour. For since the times increase in the series of the natural numbers 1, 2, 3, 4, 5, &c. and the altitudes, if the numeration be in a retrograde order from the twelfth hour, increase in the series of the unequal numbers 1, 3, 5, 7, 9, &c. the altitudes computed from the twelfth hour will be as the squares of the times 1, 4, 9, 16, 25, &c. Therefore the squares of the whole time, 144, comprehend all the parts of the altitude of the vessel to be evacuated. But a third proportional to 1 and 12 is the square of 12, and consequently it is the number of equal parts in which the altitude is to be divided, to be distributed according to the series of the unequal numbers, through the equal interval of hours. There were many kinds of clepsydræ among the ancients; but they had all this in common, that the water ran generally through a narrow passage, from one vessel to another, and in the lower was a piece of cork or light wood, which, as the vessel filled, rose up by degrees, and shewed the hour.

Clepsydræ have been much improved of late years in their construction; but as their use is now superseded by the accuracy of our modern timepieces, we shall not dwell longer upon them here.

**CLERK**, a word originally applied to a clergyman, from the Greek κληρος, *chosen*, whence it was afterwards used to denote a man of learning. In our law, it is still the designation of every person in holy orders under the episcopal dignity. The word *clerk* is now variously applied to persons in numerous offices in the law and the government, as well as to those employed in keeping merchants' books.

**CLICKS** are small pieces of iron falling into a notched wheel attached to the winchers in cutters, &c. and thereby serving the office of pauls.

**CLIMATE**, or **CLIME**, in the ancient Geography, a part of the surface of the earth, or zone, bounded by two lesser circles parallel to the equator; and of such a breadth, as that the longest day in the parallel nearer the pole exceeds the longest day in that next the equator, by some certain space, as half an hour or an hour. Vulgarly, the term *climate* is bestowed on any country or region differing from another, either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants, without any regard to the length of the longest day.

**CLINCH**, a particular method of fastening large ropes by a kind of knot and seizings, instead of splicing; and is chiefly used to fasten the cable to the ring of the anchor, and the breechings of guns to the ring-bolts in the ship's side.

**CLINCHER-WORK**, the disposition of the planks in the side of any boat or vessel, when the lower edge of every plank overlays that next below it, like slates on the roof of a house.

**CLINCHER-BUILT**, made of clincher-work.

**CLINCHING**, in sea language, is the driving a little oakum into the seams to keep out the water.

**CLINICAL**, in Medicine, is applied to the practice of visiting and treating patients.

**CLOCK**, a machine now constructed in such a manner, and so regulated by the uniform motion of a pendulum, as to measure time, and all its subdivisions, with great exactness. Before the invention of the pendulum, a balance, not unlike the fly of a kitchen jack, was used instead of it. Clocks were at first called nocturnal dials, to distinguish them from sun-dials, which shewed the hour by the shadow of the sun. The invention of clocks with wheels is ascribed to Pacificus, archdeacon of Verona, in the 9th century, on the credit of an epitaph quoted by Ughelli, and borrowed by him from Panvinus. Others attribute the invention to Boethius, about the year 510; and some to Archimedes. But we know for certain, that Edward III. gave permission to three artists to come over from Holland to England, and practise their calling here. A modern clock, as in the figure, consists of a variety of parts, which may be thus explained: P is a weight which is suspended by a cord that winds about the cylinder or barrel C, which is fixed upon the axis *a, a*; the pivots *b, b*, go into holes made in the plates T S, T S, in which they turn freely. These plates are made of brass or iron, and are connected by means of four pillars, Z, Z; the whole together being called the *frame*. The weight P, if not restrained, would necessarily turn the barrel C, with an uniformly accelerated motion, in the same manner as if the weight were falling freely. But the barrel is furnished with a ratchet-wheel, K, K, the right side of whose teeth strikes against the click, which is fixed with a screw to the wheel D D, as represented in the second figure; so that the action of the weight is communicated to the wheel D D, the teeth of which act upon the teeth of the small wheel *d*, which turns upon the pivots *e, e*. The communication or action of one wheel with another, is called the *pitching*; a small wheel like *d* is called a *pinion*, and its teeth are called *leaves* of the pinion. Several things are requisite to form a good pitching, the advantages of which are obvious in all machinery where teeth and pinions are employed.

The teeth and pinion-leaves should be of a proper shape, and perfectly equal among themselves: the size also of the pinion should be of a just proportion to the wheel acting into it.

The wheel E E is fixed upon the axis of the pinion *d*; and the motion communicated to the wheel D D by the weight is transmitted to the pinion *d*, consequently to the wheel E E, as likewise to the pinion *e* and wheel F F, which moves the pinion *f*, upon the axis of which the crown or balance-wheel G H is fixed. The pivots of the pinion *f* play in holes of the plates L M, which are fixed horizontally to the plates T S. In a word, the motion begun by the weight is transmitted from the wheel G H to the palettes I K, and by means of the fork U X riveted on the palettes, communicates motion to the pendulum A B, which is suspended upon the hook A. The pendulum A B describes, round the point A, an arc of a circle alternately going and returning. If, then, the pendulum be once put in motion by a push of the hand, the weight of the pendulum at B will make it return upon itself, and it will continue to go alternately backward and forward till the resistance of the air upon

the pendulum, and the friction at the point of suspension at A, destroys the original impressed force. But as at every vibration of the pendulum the teeth of the balance-wheel G H act so upon the palettes I K (the pivots upon the axis of these palettes play in two holes of the potence *st*,) that after one tooth H has communicated motion to the palette K, that tooth escapes; then the opposite tooth G acts upon the palette I, and escapes in the same manner; and thus each tooth of the wheel escapes the palettes I K, after having communicated their motion to the palettes in such a manner that the pendulum, instead of being stopped, continues to move. The wheel E E revolves in an hour; the pivot *e* of this wheel passes through the plate, and is continued to *r*; upon the pivot is a wheel N N, with a long socket fastened in the centre; upon the extremity of this socket *r*, the minute-hand is fixed. The wheel N N acts upon the wheel O; the pinion of which *p* acts upon the wheel *g g*, fixed upon a socket which turns along with the wheel N. This wheel *g g* makes its revolution in 12 hours, upon the socket of which the hour-hand is fixed.

From the above description it is easy to see, 1. That the weight P turns all the wheels, and at the same time continues the motion of the pendulum. 2. That the quickness of the motion of the wheels is determined by that of the pendulum. 3. That the wheels point out the parts of time divided by the uniform motion of the pendulum.

When the cord upon which the weight is suspended is entirely run down from off the barrel, it is wound up again by means of a key, which goes on at the square end of the arbor at Q, by turning it in a contrary direction from that in which the weight descends. For this purpose the inclined side of the teeth of the wheel K (as in the annexed figure) removes the click C, so that the ratchet-wheel R turns while the wheel D is at rest; but as soon as the cord is wound up, the click falls in between the teeth of the wheel D, and the right side of the teeth again act upon the end of the click, which obliges the wheel D to turn along with the barrel; and the spring A keeps the click between the teeth of the ratchet-wheel R.

We shall now explain how time is measured by the motion of the pendulum; and how the wheel E, upon the axis of which the minute-hand is fixed, makes but one precise revolution in an hour. The vibrations of a pendulum are performed in a shorter or longer time in proportion to the length of the pendulum itself. A pendulum of 39½ inches in length makes 3600 vibrations in an hour; *i. e.* each vibration is performed in a second of time, and for that reason it is called a *second pendulum*. But a pendulum of 9½ inches makes 7200 vibrations in an hour, or two vibrations in a second of time, and is called a *half-second pendulum*. Hence, in constructing a wheel whose revolution must be performed in a given time, the time of the vibrations of the pendulum which regulates its motion must be considered. Supposing, then, that the pendulum A B makes 7200 vibrations in an hour, let us consider how the wheel E shall take up an hour in making one revolution. This entirely depends on the number of teeth in the wheels and pinions. If the balance-wheel consists of 30 teeth, it will turn once in the time that the pendulum makes 60 vibrations; for at every turn of the wheel the same tooth acts once on the palette I, and once on the palette K, which occasions two separate vibrations in the pendulum; and the wheel having 30 teeth, it occasions twice 30, or 60 vibrations. Consequently this wheel must perform 120 revolutions in an hour; because 60 vibrations, which it occasions at every revolution, are contained 120 times in 7200, the number of vibrations performed by the pendulum in an hour. Now, in order to determine the number of teeth for the wheels E F, and their pinions *e f*, it must be remarked, that one revolution of the wheel E must turn the pinion *e* as many times as the number of teeth in the pinion is contained in the number of teeth in the wheel. Thus, if the wheel E contains 72 teeth, and the pinion *e* 6, the pinion will make 12 revolutions in the time that the wheel makes 1; for each tooth of the wheel drives forward a tooth of the pinion, and when the 6 teeth of the pinion are moved, a complete revolution is performed; but the wheel E

has by that time only advanced 6 teeth, and has still 66 to advance before its revolution be completed, which will occasion 11 more revolutions of the pinion. For the same reason, the wheel F having 60 teeth, and the pinion *f* 6, the pinion will make 10 revolutions while the wheel performs 1. Now the wheel F being turned by the pinion *e*, makes 12 revolutions for one of the wheel E; and the pinion *f* makes 10 revolutions for one of the wheel F; consequently the pinion *f* performs 10 times 12, or 120 revolutions, in the time the wheel E performs one. But the wheel G, which is turned by the pinion *f*, occasions 60 vibrations in the pendulum each time it turns round; consequently the wheel G occasions 60 times 120, or 7200, vibrations of the pendulum while the wheel E performs one revolution; but 7200 is the number of vibrations made by the pendulum in an hour, and consequently the wheel E performs but one revolution in an hour; and so of the rest.

From this reasoning, it is easy to discover how a clock may be made to go for any length of time without being wound up. 1. By increasing the number of the teeth in the wheels. 2. By diminishing the number of teeth in the pinions. 3. By increasing the length of the cord that suspends the weight. 4. By increasing the length of the pendulum. And, 5. By adding to the number of wheels and pinions. But in proportion as the time is augmented, if the weight continues the same, the force which it communicates to the last wheel GH will be diminished.

It only remains to take notice of the number of teeth in the wheels which turn the hour and minute hands. The wheel E performs one revolution in an hour; the wheel N N, which is turned by the axis of the wheel E, must likewise make only one revolution in the same time; and the minute-hand is fixed to the socket of this wheel. The wheel N has 30 teeth, and acts upon the wheel O, which has likewise 30 teeth, and the same diameter; consequently the wheel O takes an hour to a revolution: now the wheel O carries the pinion *p*, which has 6 teeth, and which acts upon the wheel *q q* of 72 teeth; consequently the pinion *p* makes 12 revolutions while the wheel *q q* makes one, and of course the wheel *q q* takes 12 hours to one revolution; and upon the socket of this wheel the hour-hand is fixed. Much that has been said here concerning revolutions of wheels, &c. is equally applicable to watches as to clocks.

But to speak of the striking part, in which, indeed, as well as the other part of a clock, there is room for a great variety and choice in the construction; the wheels composing this part are, the great or first wheel, moved by the weight or spring at the barrel, in sixteen or thirty hour clocks; this has usually pins, and is called the *pin-wheel*: in eight-day pieces the second wheel is commonly the pin-wheel or striking-wheel, which is moved by the former. Next to the striking-wheel is the detent-wheel, or hoop-wheel, having a hoop almost round it, wherein is a vacancy at which the clock locks. The next is the third or fourth wheel, according to its distance from the rest, called the *warning-wheel*. The last is the flying pinion, with a fly or fan, to gather air, and so bridle the rapidity of the clock's motion. To these must be added the pinion of report, which drives round the locking-wheel, called also the *count-wheel*, ordinarily with eleven notches in it, unequally distant, to make the clock strike the hours. Besides the wheels, to the clock part belongs the rash or ratch; a kind of wheel with twelve large fangs, running concentric to the dial-wheel, and serving to lift up the detents every hour, and make the clock strike: the detents or stops, which being lifted up and let fall, lock and unlock the clock in striking; the hammer, which strikes the bell; the hammer tails, by which the striking pins draw back the hammers; latches, whereby the work is lifted up and unlocked; and lifting-pieces, which lift up and unlock the detents.—For the other parts of a clock, see BALANCE, PENDULUM, and SCAPEMENT.

J. H. G. Dyar, of Vermont, in America, has invented a clock, the principles and movements of which entirely differ from those at present in use. The pendulum moves in a cycloidal arch, and performs long and short vibrations in equal times; while the pendulum of the common clock swings in the arc of a circle, making unequal vibrations in unequal times. In other respects its construction is peculiar; the hammer, which is balanced and turns on a pivot, strikes the internal limb of the bell; and the machinery of the whole is surprisingly simple, but two wheels

being required to continue the operation of eight days, without renewing the power: three wheels, it is said, will do this for a year; and four, we are told, will perpetuate the motion for a century. They may be seen at some of the clockmakers in London.

Prior's contrivance for the striking part of a eight day clock, consists of a wheel, on the face of which are cut six turns of a spiral line for counting the hours; the pins below this spiral elevate the hammer, and those above are for the use of the detent. This single wheel serves the purpose of count-wheel, pin-wheel, detent-wheel, and the fly-wheel, and has six revolutions in striking the 12 hours. The flies of clocks turn round, at a mean, above sixty times for every knock of the hammer, but this turns round only three times for the same purpose; and suppose the pivots were of equal diameters, the influence of oil on them would be as the number of revolutions in each.

In some parts of the kingdom, Glasgow to wit, the dials of public clocks have been illuminated by gas; and certainly nothing is more necessary than this addition to our night watch. A dial-plate might be made to revolve on the axis of the fixed dial. The figures shewing the hours being cut in contrary succession, and the span illuminated by a strong gas light.

One on the following plan might be adopted, exactly as it has been suggested by the editor of the "*Register of the Arts and Sciences*." A is the dial-plate of a common clock, with the

hours, &c. marked upon it, as usual; B is the proposed addition to it, for the purpose of exhibiting the time distinctly during the night; C is a light cog-wheel, placed immediately behind the day dial, having its centre fitted in the arbor of the hour-hand, and revolving with it. The night dial B we propose to be made of a plate of glass, with the hours painted upon it in black, and to revolve on an axis in its centre. The index, represented by an arrow, is fixed. The periphery of the glass plate is encompassed by a rim of brass, having cogs in its outer edge, which fit into

the cogs of the wheel C; consequently they move together; and being of equal diameters, they perform their revolutions in equal time. The time represented in our engraving is a quarter past ten; when the hour-hand has moved on to XI, (for instance,) the transparent dial B will have moved an equal space past the fixed index, and denote the same precise time. Both dials must, by this simple contrivance, invariably agree in their respective indications of the time. During the day the time is observed on the large dial, as usual; and at night a lighted lamp placed behind the transparent dial will always exhibit the time as distinctly.

CLOSE-HAULED, the arrangement or trim of a ship's sails when she endeavours to make a progress in the nearest direction possible towards that point of the compass from which the wind blows; in this manner of sailing, the keel of square-rigged vessels commonly makes an angle of six points with the line of the wind, but cutters, luggers, and other fore-and-aft rigged vessels, will sail much nearer. All vessels, indeed, are supposed to make nearly a point of lee-way when close-hauled, even when they have the advantage of a good sailing breeze and smooth water. The angle of the lee-way, however, enlarges in proportion to the increase of the wind and sea. In this disposition of the sails they are all extended sideways on the ship, so that the wind, as it crosses the ship obliquely towards the stern from forwards, may fill their cavities. But as the current of wind also unites the cavities of the sails in an oblique direction, the effort of it, to make the ship advance, is considerably diminished: she will, therefore, make the least progress when sailing in this manner. The ship is said to be close-hauled,

because at this time her tacks, or lower corners of the principal sails, are drawn close down to her side to windward; the sheets hauled close aft; and all the bowlines drawn to their greatest extension, in order to keep the sails ready.

**CLOSE QUARTERS**, certain strong barriers of wood stretching across a merchant ship, in several places; they are used as a place of retreat when a ship is boarded by her adversary, and are therefore fitted with loop-holes through which to fire the small arms; they are likewise furnished with caissons, or powder-chests, fixed upon the deck, which may be fired at any time from the close quarters upon the boarders. An English merchant ship of 16 guns, by being properly fitted with close quarters, has been known to defeat the united efforts of three French privateers who boarded her, after having engaged at some distance nearly a day and a half, with very few intervals of rest. Two of the cruisers were equipped with 12 guns each, and the other with 8. The French sailors were, after boarding, so much exposed to the continued fire of musketry, and cohorts charged with grenades, that a dreadful scene of carnage ensued, in which the decks were soon covered with the dead bodies of the enemy, several of which the boarders, in their hurry to escape, had left behind.

**CLOUD**, a visible aggregate of minute drops of water suspended in the atmosphere. The same aggregate, which in this situation is called a cloud, obtains the name of mist, when seen to arise from the earth or waters; and fog, when it envelopes and covers the observer. Yet the two latter, viewed from a greater distance or elevation, present all the appearances of clouds; while those, in their turn, become mists and fogs, in proportion as we approach and penetrate them. It is concluded, from numerous observations, that the particles of which a cloud consists, are always more or less electrified; and this fluid has hence been considered as the cause of the formation of all clouds whatever, whether of thunder, hail, rain, or snow. See METEOR.

The hypothesis which assumes the existence of vesicular vapour, and makes the particles of clouds to be hollow spheres, which unite and descend in rain when ruptured, however sanctioned by the authority of several eminent philosophers, does not seem necessary to the science of meteorology in its present state; it being evident that the buoyancy of the particles is not more perfect than it ought to be, if we regard them as mere drops of water. In fact, they always descend, and the water is elevated again only by being converted into invisible vapour.

The height of the clouds is supposed to be from about a quarter of a mile to a mile. It is common for persons by climbing very high mountains, to get above the clouds, and see them swim beneath them. The wonderful variety in the colour of the clouds is owing to their particular situation with regard to the sun, and the different reflections of his light. The different figures of the clouds result from their loose and voluble texture, revolving into any form according to the varied force of the winds. Those small clouds, sometimes seen very high, and heaped upon one another, presage rain very soon. When the horizon, at the rising or setting of the sun, appears pale and yellowish, it is a sign of the air being full of vapours, and threatens bad weather. But when it is of a light red at those times, there are but few vapours in the air, and fine weather may be expected. The quantity of vapour evaporated at any degree of heat or wind, depends on the quantity of vapour already in the atmosphere.

**COAL**, a solid inflammable substance commonly used for fuel. There are various species, 1. *Pit Coal*, is a black, compact, brittle mass, which, according to Kirwan, consists of petrol or asphaltum mixed with argillaceous earth; seldom with calcareous; and frequently also with pyrites. 2. *Culm Coal*, this has a greater portion of argillaceous earth and vitriolic acid, with a moderate portion of petrol. It burns with a flame without being consumed. 3. *Slate Coal*, contains so much earth, that it looks like common slate; but burns with a flame. There are large quarries of it at Purbeck, in Dorsetshire. 4. *Cannel Coal*, or *ampelites*, is of a dull black colour, and burns with a bright flame, but is apt to fly to pieces in the fire. This kind is used for making various toys, which appear like jet. 5. *Kilkenny Coal*, is the lightest of all, and contains the largest

quantity of asphaltum; burns with less smoke and flame, and more intensely, though more slowly, than cannel coal. 6. *Sulphurous Coal*, has a considerable portion of pyrites, whence it is apt to moulder and break when exposed to the air, after which water will act upon it. There are in it yellow spots resembling metal. 7. *Bovey Coal*, is of a dark brown colour, and of a yellow lamina and texture. The laminae are flexible when first dug, but harden when exposed to the air. It consists of wood penetrated with petrol or bitumen, and frequently contains pyrites, alum, &c. 8. *Jet*. This substance is found in France, Spain, Germany, Britain, and other countries. It is found in detached kidney-formed masses of various sizes, and is of a very deep glossy black colour, opaque and hard.

**COAL**, *Small*, a sort of charcoal prepared from the spray and brush-wood stripped off from the branches of coppice wood, sometimes formed in bavons for that purpose, and sometimes charred without binding. It is used by artificers to temper and anneal their works.

**COAL GAS**, is of the highest importance, from the beautiful light which it yields. When coals are burning on the fire, we see the stream shooting out, and inflaming when a light is held near it: this is coal gas. To obtain gas, the coals are enclosed in iron retorts, which are heated red-hot; the coal is literally dissolved, and the gas rising up in the retort, is made to pass through water and other substances, to free it from impurities. It is collected in a gasometer, from which it is transmitted by pipes to whatever distance it may be required, with the same facility as if it were water from a reservoir; indeed, with greater ease, as the level of a reservoir of water must always be higher than the place to which water is conducted; but from the buoyancy and lightness of gas, it will ascend to any height to which it may be desirable to conduct it. The gas produced from coal is chiefly the carburated hydrogen gas, which consists of carbon and hydrogen, chemically combined. This is, however, by no means in a state of purity, but is only the predominant gas in the mixture.

**COASTING**, is that part of navigation which is carried on near the coast or shore, without losing sight of land, except occasionally for a short period.

**COAT OF ARMS**, in Heraldry, was a habit worn by the ancient knights, over their armour, reaching as low as their navel. The term is used for the bearing of a person or family.

**COATING**, the application of clay or some other substance about a glass vessel, to keep it from breaking by the violence of the fire.

**COBALT**, in Chemistry, a metal, when pure, of a white colour, inclining to bluish or steel gray. At the common temperature its specific gravity is more than 8.5. It is attracted by the magnetic needle, and is itself capable of polarity. For fusion, it requires nearly the same intensity of heat as cast iron. Cobalt occurs in nature alloyed with other metals, and mineralized by oxygen, and by arsenic acid. The white cobalt ore is an alloy of cobalt and arsenic, with a little sulphur, and in some specimens a little iron, the two latter being probably accidental. The gray cobalt ore, as it has been named, is an alloy of cobalt with arsenic and iron; sometimes, also, as has been affirmed, with small portions of nickel and bismuth.

Cobalt combines with many of the metals. Its alloys are generally brittle, and none of them have been applied to any use; nor have they been much examined. The principal, or indeed almost the sole use of cobalt, is in communicating a blue colour to glass, enamel, and porcelain. Smalt and azure blue are merely cobaltic glass in fine powder. Zaffre is a flint powder, and an impure oxide of cobalt prepared by calcination of the ores.

**COBITIS**, the *Loache*, a genus of fishes, of the order of abdoninales, of which there are five species, natives of the rivers in Europe. The loache generally keeps at the bottom on the gravel, whence it is called the groundling.

**COBOOSE**, the place where the victuals are cooked on board merchant ships.

**COCCULUS INDICUS**, a poisonous berry, too frequently mixed with malt liquors to make them intoxicating. It is the fruit of the monospermum cocculus.

**COCCUS**, a genus of insects belonging to the order of hemiptera. The coccus cacti, a native of the warmer parts of

America, is the famous cochineal animal. The female, which alone is valuable for its colour, is slothful and ill-shaped. The male is scarce, and sufficient for three hundred females. It is small, slender, and active. The cochineal insect resembles the silkworm in the manner of depositing its eggs. The insects destined for this purpose are taken and put into a box lined with a coarse cloth, where they lay their eggs, and then die. The box is kept close shut till the time of placing the egg on the foliage of the cactus cochenilifer or Indian fig, called by the Spaniards nopal. At Oaxaca, in Mexico, the cochineal insects are gathered in large quantities, and the cultivation of them is the employment of the Indians. In trade there are four sorts of cochineal—mastique, campeschane, tetraschale, and sylvester. The first is the best, and the last the worst. The cochineal is esteemed in medicine as a cordial, sudorific, and febrifuge; but it is chiefly used by dyers and painters. *Coccus lacca*, or gum lac animal, is a native of the East Indies. This species fix themselves upon the succulent extremities of the young branches of the trees they inhabit, and are as it were glued thereto by a red liquid, which gradually accumulating, forms a complete cell, and is what is called gum lac. Out of this proceed the young insects, leaving the exuviae behind, which is that white membranous substance found in the cells of the stick lac. The gum lac brought to this country is principally found on the mountains on both sides the Ganges, and is of a deep red colour. *Coccus Polonicus*, or the scarlet grain of Poland, is usually met with at the root of the plant called *polygonum cocciferum*.

**COCHINEAL**, was at first supposed to be a grain, which name it still retains by way of eminence among dyers, but naturalists soon discovered that it was an insect, a species of the coccus. Fine cochineal, which has been well dried and properly kept, ought to be of a gray colour inclining to purple. The gray is owing to a powder which covers it naturally, a part of which it still retains: the purple tinge proceeds from the colour extracted by the water in which it has been killed. Cochineal will keep a long time in a dry place. Hellot says, that he tried some 130 years old, and found it to produce the same effect as new.

**COCHLEA**, the same as screw: being thus called in consequence of its resemblance to the spiral shell of a snail, called by the Latins *cochlea*.

**COCKBOAT**, a small boat used on rivers near the shore. In ancient days a cock was the general name of a yawl.

**COCKPIT**, in a ship, is near the apartments of the surgeon and his mates, being the place where the wounded men are dressed. It is situated near the after hatchway, and under the lower gun-deck.

*Fore Cockpit*, a place leading to the magazine passage, and the boatswain's, gunner's, and carpenter's store rooms; in large ships, and during war time, the boatswain and carpenter generally have their cabins in the fore cockpit, instead of being under the fore-castle.

**COCOS**, in Botany, a genus belonging to the natural order of palmæ, and of the monoecia hexandria class. There are five species. The principal is, *cocos nucifera*, or cocoa-nut tree. It frequently grows to the height of sixty feet, and is smaller in the middle than at top and bottom. Owing to the load of nuts which it bears, it leans to one side. The colour is of a pale brown, and the bark smooth. The leaves are often fourteen or fifteen feet long, and about twenty-eight in number. The nuts hang at the top of the trunk in clusters of a dozen each. The nut has, next the stem, three holes closely stopped. When the kernel begins to grow, it incrusts the inside with a substance like jelly; this hardens and increases till it becomes white. The quantity of liquor in a full-grown nut is about a pint, and is pleasant to the taste. The husky tegument of the nut consists of tough, stringy filaments, like coarse oakum. The leaves are made into brooms, mats, sacks, and other useful articles.

**CODE**, a collection of the laws and constitutions of the Roman emperors, made by order of Justinian.

**CODEX**, a book or tablet, used by the ancients.

**CODICIL**, a writing, added by way of supplement when a thing has been omitted, that the testator wishes to appear in his last will.

**CO-EFFICIENTS**, in Algebra, are numbers or letters prefixed to other letters, or unknown quantities, into which they are supposed to be multiplied; and, therefore, with such letters, or the quantities represented by them, making a product, or co-efficient product. See ALGEBRA.

**COFFEA**, or the COFFEE TREE, a genus of the monogynia order, in the pentandria class of plants, ranking in the natural method under the 47th order stellatæ. There are 10 species, the principal of which is a native of Arabia Felix, which rises about 16 or 18 feet in height: the main stem growing upright, is covered with a light brown bark; the branches are produced horizontally and opposite, crossing each other at every joint. The leaves also stand opposite, and when full grown, are about four or five inches long, and two broad in the middle, decreasing towards each end: the bodies are waved, and the surface is of a lucid green. The flowers, which are white, are produced in clusters at the root of the leaves, sitting close to the branches. The fruit resembles a cherry. It grows in clusters along the branches, under the axillæ of the leaves. It is at first of a green colour, and when of a deep red, is gathered for use. The coffee tree is cultivated in Arabia, Persia, the East Indies, and America. It is also raised in botanic gardens, in several parts of Europe. Coffee is said to assist digestion, and is good in relieving the headache; and for very weak constitutions, should be drank immediately after dinner. It is taken in large quantities by the Turks and Arabs.

**COFFER**, in Fortification, is a hollow lodgment across a dry moat, on which are raised pieces of timber, and hurdles filled with earth, serving as a parapet with embrasures. The use is for the besieged to defend the ditch, and to repulse the besiegers.

**COFFER DAM**, a term applied by engineers to denote the enclosures formed for laying the foundation of piers and other works in water, to exclude the surrounding fluid, and thus forming a protection both to the work and workmen.

**COGNATION**, in Civil Law, a term for that line of consanguinity between males and females, both descended from one father.

**COGNISOR**, in Law, one that passeth or acknowledgeth a fine of lands or tenements to another.

**COGNOVIT ACTIONEM**, in Law, is an acknowledgment by a defendant, or confession, that the plaintiff's cause of action is just, and therefore suffers judgment to go against him.

**COG WHEEL**. Wheels acting upon each other are the instruments by which the transmission of mechanic force from one part of a system of machinery to another is commonly and conveniently effected. The due connexion of the moving parts is accomplished either by the mutual action of properly formed teeth, in some instances called *Cogs*, by straps or endless bands, or, by the friction of one face of a wheel against another.

Among the ingenious inventions of the present day, for the communication of motion in machines, in lieu of the ordinary cog or toothed wheels, the invention of Lewis Gompertz, Esq. of the Kennington Oval, Surry, is so perfectly original as to require the most extensive publicity. The following is its description in the words of the inventor's specification of the patent which he obtained for this improvement in the arts, dated April 27th, 1814.

"One of the wheels I call the pin wheel, because it is provided with pins, marked B C D E, see *Plate*, figs. 1, 2, and 5, which pins may be furnished with friction rollers, and which project perpendicularly from its plane, and communicate motion to the other wheel, called the curve wheel, (or *vice versa*,) by entering curved grooves G H I K, made in the surface of it, as shewn in the perspective view, fig. 5. The axes, and consequently the planes of the two wheels, are so inclined to each other, that the ends of the pins B C are beneath the surface of the curve wheel, and therefore enter into the grooves. But, in consequence of the inclination of the wheels as the pins approach the point D, or come to the line between the centre of the wheels, their ends come to the surface of the wheel, so as to leave the grooves; and as they proceed towards E, they are so completely above the wheel as to pass over without touching it. The manner of action is this: the pin C is engaged in the groove G, and the pin B is on the point of entering H; by the revolution of the pin wheel its pins B and C act in the grooves,

and pressing in their curves, turn the curve wheel round upon its centre; and as the pins in succession quit the grooves in the same manner as the pin D is supposed to have quitted the groove K, the other pins very soon after enter the next groove but one, in the same manner as B is entering into H, and by this means, before any pin leaves its groove, the succeeding pin has just entered, and a constant action of the pins in the groove is kept up. The law of the action depends upon the nature of the curves, which may be varied at pleasure, so that they will turn each other with an equal velocity, and with a perfect regular motion; or by an irregular one, or the curves may be made to turn with twice or three times the velocity, or in almost any ratio required, also to turn each other in either direction; thus, in figs. 1 and 5, both the wheels turn round in the same direction as shewn by the arrows, but in fig. 2 the grooves are differently curved, and they turn contrary ways to each other. A manner of finding the curves for these grooves is explained in fig. 4. First describe the circle *F I*, for the size of the curve wheel; then draw a circle, *A B C D*, for the pin wheel, and divide it into the number of pins it is intended to have, for example twelve; subdivide the spaces between each of the pins *D C* and *C B* into any number, eight for example, and figure the divisions, as shewn next; on the centre *F* draw a circle through each of the said divisions, also a circle *A R T* passing through the centre of the pin wheel. Now, divide the circumference of this circle into as many parts as the wheel is to have curves, this will depend upon the ratio the velocities of the wheels are to bear to each other; thus, if it is to turn twice for once of the pin wheel, there must be half as many curves as there are pins; therefore in the drawing, the circle *A R T* is to be divided into 6, and each sixth is subdivided into as many equal parts as the spaces *C* and *D* were, viz. eight. These spaces are to be numbered as shewn. With this preparation proceed to set out the curves, by taking the radius *A D* in the compasses, and setting one point in the division marked 3, between *T* and *A*; make a mark at *h*, upon the external circle, also numbered 3, towards that side where the curve wheel is to be elevated, (by *side*, is not meant side of the wheel, but side of the position of the wheel, or of absolute space, as the wheel changes in turning, and what is high in one instance is low in the next,) because it passes through the division 3, between *B* and *C*. This mark will be the first point of one of the curves. Then, from the division 4, mark the circle 4 for the second point; next from the point 5 to the circle 5; and so on through the whole number of circles. This will find a number of points, forming a curve *G C x*, which will be the centre line of the intended groove. And to find its breadth, describe small circles round each of these points, rather larger than the pins, as drawn. The edges of the grooves may then be drawn as tangents to these circles. The succeeding curves *H* and *I* are found in exactly the same manner from the succeeding divisions on the great circle, beginning on the division 3, between *A R*, and so on all round. On the opposite side of the circle are shewn curves *g h i*, proper for giving the curve wheel an equal velocity with the pin wheel, and there will therefore be twelve of these curves in the whole. The preparation is exactly the same, but the great circle instead of six is divided into twelve, as at the points *a r* and *t*, and each of these are subdivided into eight (or the same number as between *d* and *C*;) then the curves are set out from these points exactly as before: in both these cases the wheels are considered as revolving in the same direction, as shewn by the arrows figs. 1 and 5. If it is required that they should turn each other in opposite directions, the curves must be reversed, as shewn in fig. 2. To set out these curves, the same lines and divisions as in fig. 4 are used; but the division between *T A* and *A R* must be figured the contrary way, namely, beginning at *R* and proceeding to *A*; then setting one foot of the compasses at 5, between *A* and *R*, and the other leg in the first circle (marked 3) towards that side where it is meant to be elevated, and as one leg is moved towards *T*, move the other leg towards the centre; and for the next curve begin with the next same number towards *T*, and so on, and mark as before. A reverse curve will here be produced, as shewn dotted at *l C m*, and a wheel, constructed with these curves, as in fig. 2, will turn in a contrary direction to the pin wheel, as shewn by the arrows.

"Fig. 3 represents a curve wheel, with six curves, which therefore revolve twice for once of the pin wheel; but the curves are so arranged, that for two-thirds of its revolution the curve wheel revolves at the rate of four to one of the pin wheel, viz. while the pins are acting in the curves *G* and *K*, the four remaining curves *I L M H* are close together, and the action of the pins, when in them, only advances the curve wheel double the space of the pin wheel; but the motion of the curve wheel, even while the pins are acting in these grooves, may be made irregular, to almost any required law; thus, at the external parts *I L M*, where the pins first enter, the grooves are curved the same as fig. 2, and therefore the pins will in these positions turn the curve wheel twice as fast as they move themselves, but on entering and moving through the returned parts *i l m* of the curves, the pin communicates a recoiling motion to the curve wheel, which continues till the pin enters the last portions *t v w*, and at the same time a succeeding pin enters the next curve; this again actuates the curve wheel, as in the first instance.

"This wheel is set out on the same principle as the others, see fig. 6, which is prepared exactly as before, except the dividing of the great circle, which must in all cases be done according to the motion the curve wheel is intended to have given to it; in the present instance it is first divided in 3, at *A R S*, and each of these subdivided into eight; then from No. 3, between *R* and *A*, mark on the outside circle 3; from 4 to the circle 4; and so on till the curve *G* is brought as far as the next circle marked 3, from which place only move the leg in the large circle half a division; then set out *K*, by following the same process on another part of the great circle, excepting that the leg in the large circle is continually to be moved a whole division. To obtain the four other curves, take the space from fig. 3 *m* to 3 *q*, which is one-third of the whole circle, and divide it into four, viz. at *m n o p q*; then each of these spaces being subdivided into four, as shewn by the figures 40, 50, and 60, produce the curves thus: begin at *m*, and mark on the external circle for the first division of *H*, then from 40 mark on the circle 4, and continuing this till six circles, towards the centre, are marked, and the curve *H* is finished; this will have brought the compasses to one division beyond *n*; for the returned part *h* mark the two next circles towards the centre, and by returning one division for each in the large circle, this brings the compasses back to 60, and advancing from that point, begin the interior part *w*, and also the part *M* of the next curve, which is completed by a repetition of the same process on the succeeding part of the circle, as is likewise *L* and *I*; but the interior end *x* of the latter must be set out from the great divisions of the circle *R S*; thus, when the part *i* is ended from 69 next to *q* 3, advance the compasses to the points 4, 5, 6, and 7, for marking the successive circles till the curve is completed.

"This is given only as an example of the manner of making a wheel to turn with any required degree of irregularity in its motion; but I claim all varieties of curves which may be made to act on the principles I have described, to communicate regular or irregular motion from the pins of a wheel."

**COHESION**, that species of attraction, which, uniting particle to particle, retains together the component parts of the same mass; being thus distinguished from *adhesion*, or that species of attraction which takes place between the surfaces of similar or dissimilar bodies.

Whatever may be the cause of cohesion, its effects are evident and certain, and the different degrees of it is what constitute bodies of different forms and properties; at least, this is the opinion of Sir Isaac Newton, and other eminent philosophers.

Various experiments have been made by different authors, to ascertain the power of cohesion, in bodies of different textures; as woods, metals, glass, &c. These experiments have generally been made on cylindric bars, an inch, or certain parts of an inch, in diameter; and as it has been proved, that the direct cohesive strength of a body is in the joint ratio of its primitive elasticity, toughness, and area of its section, it follows, that having ascertained the cohesive power with any given section, the same may be found for the same substance for any other section, and thus the experiments of different authors compared with each other.

The following table shews the weights which were necessary to tear asunder rods of different substances, whose bases were each a square inch, the weights being applied in the direction of their length.

| METALS               | Lbs. Avoirdupois. | WOODS              | Lbs. Avoirdupois. |
|----------------------|-------------------|--------------------|-------------------|
| Steel, .....         | 135000            | Beech, oak, .....  | 17300             |
| Iron bar, .....      | 74000             | Alder, .....       | 13900             |
| Cast iron, .....     | 50100             | Elm, .....         | 13200             |
| Copper, cast, .....  | 28600             | Mulberry, .....    | 12500             |
| Silver, ditto, ..... | 41500             | Willow, .....      | 12500             |
| Gold, ditto, .....   | 22000             | Ash, .....         | 12000             |
| Tin, ditto, .....    | 4000              | Plum, .....        | 11800             |
| Bismuth, .....       | 2900              | Elder, .....       | 10000             |
| Zinc, .....          | 2600              | Fir, .....         | 8330              |
| Antimony, .....      | 1000              | Pitch, pine, ..... | 7656              |
| Lead, cast, .....    | 860               | Cypress, .....     | 6000              |
|                      |                   | Poplar, .....      | 5500              |
|                      |                   | Cedar, .....       | 4880              |

Other experiments have been made to ascertain the strength of cohesion in bodies, when placed horizontally, and loaded with weights in different parts; but as we shall have occasion to return to this subject under the article *STRENGTH of Materials*, we shall, in this place, merely state the result of Muschenbroek's experiments on a few of the most common woods. For this purpose he fixed pieces of wood, by one end, into a square hole in a metal plate, and hung weights towards the other end, till they broke at the hole. The weights, and their distances from the point of support, are shewn in the following table:—

| WOODS.       | Dist. in Inches. | Weight in oz. |
|--------------|------------------|---------------|
| Pine, .....  | 9½               | 36½           |
| Fir, .....   | 9                | 40            |
| Beech, ..... | 7                | 56½           |
| Elm, .....   | 9                | 44            |
| Oak, .....   | 8½               | 48            |
| Elder, ..... | 9½               | 48            |

In the above table the rods were rectangular parallelepipeds, and the side of their square section .26 of an inch.

Coulomb found the lateral cohesion of brick and stone only  $\frac{1}{4}$  more than the direct cohesion; which, for stone, was 215 lb. for a square inch; for good brick, from 280 to 300. Count Rumford found the cohesive strength of a cylinder of iron, an inch in diameter, 63466, or 63173 lb.; the mean, 63320; which is only  $\frac{1}{10}$  more than Emerson's result. Sickingen makes the comparative cohesive strength of gold, 150955; of silver, 190771; of platina, 262361; of copper, 304696; of soft iron, 362927; of hard iron, 559880. Guyton makes platina a little stronger.

**COILING**, is a sort of serpentine winding the ropes, by which they occupy a small space, and are not liable to be entangled amongst one another in working the sails. Each winding of this sort in a cable is called a *fake*, and one range of fakes is called a *tier*; there are generally from five to seven fakes in a tier, and three or four tiers in a cable's length: the small ropes are frequently coiled by hand, and hung upon cleats to prevent their being entangled amongst one another, in traversing, contracting, or extending the sails.

**COINING**, the art of making money, is performed either by the hammer, or the mill and steam-engine. By either of these methods the pieces of metal are stamped or struck with punches or dies, on which are engraven the sovereign, effigies, arms, legend, &c. The punch consists of a highly tempered piece of steel, upon which the coin is sunk in relief, and again upon the matrix, which is another piece of steel some four inches long, formed square at the bottom, and rounded at its top. The moulding of the border and letters is added on the matrix with small and sharp steel punches, and when it is thus finished, it is called the die. In coining with the mill, the bars or plates of gold or silver, after having been moulded, and taken out of the mould, are scraped and brushed, and passed several times through the mill to flatten them, and bring them to the just thickness of the specie to be coined. But the plates of gold are heated again, and quenched in water before they pass through the mill, which renders them more ductile: those of silver pass the mill just as they are, without any

heating; and when afterwards heated, they are left to cool. The plates thus reduced as nearly as possible to their thickness, are cut into round pieces the size of the intended specie. The cutting instrument has its upper end formed into a screw; which being turned by an iron handle, lets the steel, well sharpened, in form of a punch-cutter, fall on the plates; and thus a piece is punched out. These pieces are now adjusted, and brought, by filing or rasping, to the weight of the regulated standard; what remains of the plate between the circles is melted again. The pieces are adjusted in a fine balance; and those too light are separated from those which are too heavy; the first to be again melted, and the second to be filed down. The mill through which the plates pass can never be so just but there will be some inequality.

The pieces are called blanks, and are carried to the *blanching* or *whitening-house*, where the gold pieces have their colour given them, and the silver ones are whitened. This is done by heating them in a furnace, and when taken out and cooled, boiling them successively in two copper vessels, with water, common salt, and tartar, and after that scouring them well with sand, and washing them with common water, drying them over a wood fire, in a copper sieve, into which they are put when taken out of the boilers. In England, the standard for gold is eleven parts of pure metal and one of alloy; for silver, 11 oz. 2 dwts. of pure silver, and 18 dwts. alloy, making together 1 lb. troy weight.

In the machinery invented for coining, by the late Messrs. Boulton and Watt, and lately introduced into the Royal Mint, London, the screw presses for cutting out the circular pieces of metal, are worked with great facility, and both the edges and the faces of the money are coined at the same time, with such superior excellence, and cheapness of workmanship, as will prevent clandestine imitation, except in a very limited degree indeed. By means of this machinery, four boys can strike 30,000 pieces of money in an hour: the machine acting at the same time as a register in keeping an unerring account of the number of pieces that have been struck!—*See MINT*.

**COKE**, a preparation of fossil coal, whereby it is deprived of the naptha, bitumen, or asphaltum, it may contain, so that when applied to certain purposes, it may not communicate a bad flavour or bad qualities. Coke is made in very large ovens, principally from the refuse of brush-coal, with which some pits abound; the coal in them being extremely brittle, and rarely coming away in large pieces. In great towns which are lighted with gas, coke is obtained in great abundance from the gas-works, being left in the retorts after the gas is driven off by the heat.

**COLD**, in common language, denotes the sensation which is felt, or the effect which is produced, by the abstraction of heat; that is, heat and cold are opposite to each other, and the existence or increment of the one, is equal to the want or decrement of the other; so that the same degree of temperature may be called hot or cold, according as it is compared with a colder or hotter temperature. Thus the climate of Great Britain is a cold climate, in comparison with that of the West India islands; and a hot climate, in comparison with that of Siberia. If a man warms one of his hands near a fire, whilst he cools his other hand by means of ice; and if afterwards he plunges both his hands in a basin of water of the common temperature of the atmosphere, that water will feel cold to the hand that has been heated, and hot to the other hand. From this it appears, that cold is not any thing real, but merely a privation of heat; so that instead of saying, that a body has been cooled to a certain degree, it may with equal truth and propriety be said, that the body has been deprived of heat to that certain degree. *See FREEZING*.

Notwithstanding the simplicity of this theory, and the conviction which seems to accompany it, philosophers have often entertained doubts concerning it; and they have endeavoured to inquire into the real state of the matter, by devising experiments capable of demonstrating whether the cause of heat was any thing real, and that of cold only a privation or diminution of the former; or, *vice versa*, whether the cause of cold was any thing real, and that of heat a diminution; or, lastly, whether the production of heat, and the production of cold, were not owing to two distinct principles or elements. On the supposi-

tion that the cause of one of those effects only is real, it is much more natural to suppose, that the cause of heat is the real principle or element; since its effects, *viz.* enlargement of the bulk of bodies, the separation of their parts, &c. are such as must be produced by the introduction of something real; and the abstraction of this principle may naturally produce the effects of cold, such as contraction of the bulk of bodies, agglutination, &c.; whereas it would be unnatural to suppose, that a body contracts its bulk, as its parts come into closer contact, because something else has been introduced amongst them. With respect to the last supposition, *viz.* whether the effects of heat and those of cold be not owing to two distinct principles, a few arguments, and the equivocal result of a few experiments, have, at times, been adduced in support of it. But the general and prevailing opinion among the philosophers is, that a single element, called caloric, produces heat, or the effects of expanding bodies separating their parts, &c.; and that cold is only a relative expression; that is, meaning only the decrement of heat; so that real or absolute cold consists only in the total abstraction of caloric; and, that such a point, *viz.* the zero of heat, may be determined, has been shewn by the experiments, the discoveries, and the calculations of Irvine, Black, Crawford, and others; but it is impossible, in this place, to enter into an investigation of the methods made use of in determining this remarkable point. See ICE.

**COLEOPTERA**, the beetle tribe of insects, comprehending all those with four wings, the external pair of which are hard, rigid, and opaque, forming a kind of covering for the inner. There are 56 genera of this order.

**COLIC**, a severe pain in the lower venter, so called because the disorder was thought formerly to be in the colon. There are different kinds, as the windy colic, the bilious, the hysteric, the nervous, and the Devonshire colic.

**COLLAR**, an ornament consisting of a chain of gold, with devices and ciphers, worn by the knights of the different orders. *Collar of a ship*, is a rope fastened about the beak-head, into which the dead-man's eye is seized that holds the main-stay; also the rope wound about the head of the main-mast.

**COLLATERAL**, those relations which proceed from the same stock, but not in the same ascending or descending line.

**COLLATION**, is the giving or bestowing of a benefice on a clergyman by the bishop, who is the patron thereof.

**COLLIMATION**, LINE OF, on a telescope, is a line passing through the intersection of those wires that are fixed in the focus, and the centre of the object-glass.

**COLLISION**, in Mechanics and Physics, is the meeting and mutual striking of two or more bodies, one of which, at least, is in motion. The most simple of the problems relating to collision was that of a body proceeding to strike against another at rest, or moving before it with less velocity, or approaching towards it. In the mutual percussion of several bodies, the absolute quantity of motion of the centre of gravity is the same after as before the shock. Farther, when the bodies are elastic, the relative velocity is the same after as before percussion. All this, however, is upon the supposition, that bodies are either perfectly hard, or perfectly elastic; but as there do not exist in nature any bodies which we know of, either the one or the other of these kinds, the usual theories are of little or no service in practical mathematics.

**COLLYRIUM**, a topical remedy for inflammations of the eyes. The best is a small portion of brandy and spring water.

**COLONNADE**, in Architecture, a peristyle of a circular figure, or a series of columns disposed in a circle, and insulated withinside.

**COLOUR**, in Natural Philosophy, is that property of bodies which affects the sight only; or that property possessed by the elementary rays of light, separated by any means whatever, of exciting in us different sensations according to their different refrangibility. Thus colour may be considered in two respects, as it regards bodies in general, and as it is produced by solar light. See OPTICS.

Before the time of Newton, the ideas of mankind concerning colour were very vague and unsatisfactory. The Pythagoreans called colour the superficies of bodies: Plato said that it was a flame issuing from them: according to Zeno, it was the first

configuration of matter: and Aristotle said it was that which made bodies actually transparent.

Dr. Hooke imagined, that colour is caused by the sensation of the oblique or uneven pulses of light; which being capable of no more than two varieties, he concluded there could be on more than two primary colours. It was also an opinion, that the solar light was simple and uniform, without any difference or variety in its parts, and that the different colours of objects were made by refraction, reflection, or shadows. But Newton taught them the errors of their former opinions; he taught them to dissect a single ray of light with the minutest precision, and demonstrated that every ray was itself a composition of several rays all of different colours, each of which when separate held to its own nature, simple and unchanged by every experiment that could be tried upon it. Or, to be more particular, light is not all similar and homogeneous, but compounded of heterogeneous and dissimilar rays, some of which, in like instances, being more refrangible, and others less refrangible, and those which are most refrangible are also most reflexible; and according as they differ in refrangibility and reflexivity, they are endowed with the power of exciting in us sensations of different colours.

Newton's theory of light and colours is striking and beautiful in itself, and deduced from clear and decisive experiments. 1st. That lights which differ in colour, differ also in degrees of refrangibility. 2d. That the light of the sun, notwithstanding its uniform appearance, consists of rays differently refrangible. 3d. That those rays which are more refrangible than others, are also more reflexible. 4th. That as the rays of light differ in degrees of refrangibility and reflexivity, so they also differ in their disposition to exhibit this or that particular colour; and that colours are not qualifications of light derived from refractions or reflections of natural bodies, as was generally believed, but original and connate properties, which are different in different rays, some rays being disposed to exhibit a red colour and no other, and some a green and no other, and so of the rest of the prismatic colours. 5th. That the light of the sun consists of violet-making, indigo-making, blue-making, green-making, yellow-making, orange-making, and red-making rays; and all of these are different in their degrees of refrangibility and reflexivity; for the rays which produce red colours are the least refrangible, and those that make the violet the most; and the rest are more or less refrangible as they approach either of these extremes, in the order already mentioned; that is, orange is least refrangible next to red, yellow next to orange, and so on; so that to the same degree of refrangibility there ever belongs the same colour, and to the same colour the same degree of refrangibility. 6th. Every homogeneous ray, considered apart, is refracted according to one and the same rule, so that its sine of incidence is to its sine of refraction in a given ratio; that is, every different coloured ray has a different ratio belonging to it. 7th. The species of colour, and degree of refrangibility and reflexivity, proper to any particular sort of rays, is not mutable by reflection or refraction from natural bodies, nor by any other cause that has been yet observed. When any one kind of rays has been separated from those of other kinds, it has obstinately retained its colours, notwithstanding all endeavours to bring about a change. 8th. Yet seeming transmutations of colours may be made, where there is any mixture of divers sorts of rays; for, in such mixtures, the component colours appear not, but, by their mutually alloying each other, constitute an intermediate colour. 9th. There are therefore two sorts of colour, the one original and simple, the other compounded of these; and all the colours in the universe are either the colours of homogeneous, simple light, or compounded of these mixed together in certain proportions. The colours of simple light are, as we observed before, violet, indigo, blue, green, yellow, orange, and red, together with an indefinite variety of intermediate gradations. The colours of compounded light are differently compounded of these simple rays, mixed in various proportions: thus a mixture of yellow-making and blue-making rays exhibits a green colour, and a mixture of red and yellow makes an orange; and in any colour the same in specie with the primary ones, may be produced by the composition of the two colours next adjacent in the series of colours generated by the prism, whereof the one is next

more refrangible, and the other next less refrangible. But this is not the case with those which are situated at too great a distance; orange and indigo do not produce the intermediate green, nor scarlet and green the intermediate yellow. 10th. The most surprising and wonderful composition of light is that of whiteness; there is no one sort of rays which can alone exhibit that colour; it is ever compounded, and to its composition all the aforesaid primary colours are requisite. 11th. As whiteness is produced by a copious reflection of rays of all sorts of colours, when there is a due proportion in the mixture, so, on the contrary, blackness is produced by a suffocation and absorption of the incident light, which being stopped and suppressed in the black body, is not reflected outward, but reflected and refracted within the body till it be stifled and lost.

This method of accounting for the different colours of bodies, from their reflecting this or that kind of rays most copiously, is so easy and natural, that his system quickly overcame all objections, and to this day continues to be almost universally believed. It is now commonly acknowledged, that the light of the sun, which to us seems perfectly homogeneous and white, is composed of no fewer than seven different colours, *viz.* red, orange, yellow, green, blue, purple, and violet or indigo. A body which appears of a red colour, has the property of reflecting the red rays more powerfully than any of the others; and so of the orange, yellow, green, &c. A body which is of a black colour, instead of reflecting, absorbs all, or the greatest part of the rays that fall upon it; and, on the contrary, a body which appears white, reflects the greatest part of the rays indiscriminately, without separating the one from the other.

*Colours used in Drawing and Painting.*—*Red Colours are:* Lakes. This term denotes those colours which are formed by the combination of alumine, or the oxide of tin, with the colouring matters of vegetables. The lakes chiefly used are red colours, of different qualities, according to the basis and colouring matter employed; and are known by the names of *Carmine*, *Florence-lake*, and *Madder-lake*.

*Carmine*, a very rich bright crimson colour, stands well in water. For the preparation of carmine, take four ounces of finely-pulverized cochineal, which pour into four quarts of rain or distilled water, boiled previously in a *pewter* kettle, and boil the whole for six minutes; add, during the boiling, two drachms of pulverized crystals of tartar. Eight scruples of Roman alum, in powder, must be then added, and the whole be kept on the fire one minute longer. As soon as the gross powder has subsided, and the decoction become clear, decant it into large cylindrical glasses covered over, and kept undisturbed till a fine powder is observed to have settled at the bottom. Then pour off the liquor from this powder, which is to be gradually dried. From the liquor still coloured, the rest of the colouring matter may be separated by the solution of tin, when it yields a carmine little inferior to the former.

*Florentine-lake*, the kind in general use, and known by the name of *lake*, is used in water, and also in oil, but does not stand; it is a very beautiful colour at first, and there is no substitute that will completely answer the purposes of lake. The best sort is prepared from the sediment of cochineal that remains in the kettle after making carmine, adding a small quantity of cochineal or brazil-wood, and precipitating the colouring matter with a solution of tin.

*Madder-lake*, a colour lately brought into use, is not so bright and rich a colour as the last-mentioned lakes. It has this valuable advantage, it stands much better, and answers many of the purposes of Florence-lake.

*Rose-lake*, generally called *rose-pink*, is made by a basis of chalk, coloured by Brazil or Campeachy wood. It does not stand, and is only used for house-painting and paper-hanging.

*Vermilion*, is a bright scarlet pigment, formed from sulphur and quicksilver; its brightness, and inclining to a crimson hue, denotes its goodness. It is a very useful colour in oil, and stands well; but as a water-colour it is apt to turn black.

Red lead or minium, is lead calcined till it acquires a red colour, by exposing it with a large surface to the fire. It is also made from *litharge*, a calx or oxide of lead; but it is not so good as when made directly from metallic lead. This colour

is apt to become black, both in water and oil. It is therefore seldom used, but for very coarse purposes.

Indian red, is sometimes used instead of lake, and it might be useful, had it not the property of appearing stronger after some time. Never use it as a water colour. In oil, this effect does not take place.

Venetian red, is a native red ochre, rather inclining to the scarlet than the crimson hue; it differs little from the common Indian red. It is fouler, and chiefly used by house-painters.

Spanish brown, an earthy substance, found in the same state in which it is used; is nearly of the same colour as Venetian-red, but coarser. It is only used for the commonest purposes, though it does not change.

Light red, or burnt ochre, is common yellow ochre, heated red-hot, till the colour changes from a yellow to a red. It is an excellent colour, both in water and oil, having the quality of standing well.

Red chalk, the same substance used for drawing on paper, in the manner of a crayon, is very much like light red, and is used instead of it, for some purposes. It stands well, and is used both in water and oil.

Burnt Terra di Sienna, made by calcining raw terra di Sienna till it acquires a red colour, a very rich tint, and much used in water and oil, as it stands well in both.

*Blue Colours.*—Ultramarine, is prepared from *lapis lazuli*, by calcining and washing it very clean. When genuine, it is the brightest, the most beautiful of all colours, and stands well. It is much valued, and used in oil, and means have been found to levigate it sufficiently for water-colour drawings.

Ultramarine ashes, the residuum after washing the lapis lazuli, in which a portion of the ultramarine still remains, is very subject to be adulterated, and not so bright as ultramarine, being like that colour with a tint of red and white in it, yet when genuine it stands well.

Prussian blue, is iron combined with prussic acid. It is made in the following manner:—Two parts of purified potash are intimately blended with three parts of dried and finely pulverized bullock's blood. The mass is first calcined in a covered crucible, on a moderate fire, till no more smoke or flame appear; after this, it is brought to a complete, yet moderate ignition. Or equal parts of potash and finely powdered coals, prepared from bones, horns, claws, &c. are mingled, and heated in a covered crucible to a moderate redness. Either of these two calcined masses is, after cooling, lixiviated with boiling water, and the lixivium filtered. Nothing remains now but to make a solution of one part of green vitriol and two parts of alum; and to add to it, while yet hot, the above lixivium, little by little however, and to separate the greenish-blue precipitate, which then forms, by means of a filtre. If afterwards a slight quantity of diluted muriatic acid be affused upon this precipitate, it assumes a beautiful dark blue colour. The operation is terminated byedulcorating and drying the pigment thus prepared. Prussian blue is an extremely beautiful colour when properly prepared, and stands tolerably well. Common Prussian blue is apt to contain some iron, which causes it to turn greenish or olive.

Verditer, a blue pigment, obtained by adding chalk or whitening to the solution of copper in aquafortis, is prepared by the refiners, who employ for this purpose the solution of copper, which they obtain in the process of parting, by precipitating silver from aquafortis by plates of copper. Common verditer is made in Sheffield and Birmingham, from the sulphate of copper. Verditer is only used for coarse purposes, and chiefly by paper-stainers. It has been sometimes called *Sanders blue*, from the term *cendres-blues*, or blue ashes.

Indigo, extracted from a plant called the anil, that grows in the East and West Indies, is not so bright as Prussian blue, but it has the advantage of being more durable. It is the blue generally used in drawings. It cannot be dissolved by water, but may by the sulphuric acid; it then forms *Scott's liquid blue*, used for colouring silk stockings, &c.

Smalt is a glass covered with cobalt, and ground to a fine powder. Its coarseness prevents its being used much for painting in oil or water. It is employed sometimes by strewing it upon a ground of oil paint. It is also used in enamel painting and the colouring of porcelain, as it stands well.

Bice, is smalt more finely levigated.

**Yellow Colours.**—Indian yellow, the brightest of all yellows for water-colours, is not durable. It is said to be procured from the urine of the buffalo. In India, it is a common and cheap colour; the natives using it for colouring their calicoes, which they do without any mordant, so that the colour is washed out again when the cloth is dirty.

King's yellow, is orpiment refined, a substance dug out of the earth, and consisting of sulphur joined to arsenic; it may also be prepared by subliming sulphur with arsenic. It is of a bright yellow, but does not stand well; it is a strong poison, and great caution must be used in employing it.

Naples yellow, a very durable and bright yellow, comes from Naples. It is prepared from lead and antimony.

Yellow ochre, an earth naturally coloured by oxide of iron, is a cheap colour, and not very bright, but valuable, because it stands well. Roman ochre is a superior yellow ochre, of a rich tint.

Dutch pink, formed of chalk, coloured with the juice of French berries, or other vegetables affording a yellow colour, does not stand, and is chiefly used for common purposes.

Gamboge, a gum brought from the East Indies, dissolves readily in water, and is a fine serviceable yellow. It is used only in water.

Masticot, an oxide of lead, prepared from calcining white lead, is very little used, the colour not being bright.

Gall stones. This is a hard substance, formed in the gall-bladders of oxen; or it may be obtained from the gall of other animals. It is a rich colour, but does not stand.

Raw Terra di Sienna, a native ochreous earth, brought from Italy, is a fine warm colour, and stands well.

French berries. A liquor may be extracted from these, useful as a stain for coarse purposes; but it does not keep its colour.

Turmeric root and saffron, may be used for similar purposes.

Orange-lake, is the tinging parts of arnatto, precipitated together with the earth of alum. It does not stand.

Brown pink, is the tinging part of a vegetable substance precipitated upon the earth of alum. It is a rich greenish yellow, but does not stand.

**Green Colours.**—There are few colours so useful as green; and it is, therefore, the practice with artists to form their greens by the mixture of blue and yellow, and by varying these, a vast variety of green tints are obtained.

Sap green, is the concreted juice of the buckthorn berries. It is used only in water, and is employed chiefly in flower-painting, colouring prints, &c.

Verdigris, is an imperfect oxide of copper, combined with a small portion of acetite, carbonic acid, and water. It is prepared in large quantities, chiefly in France, near Montpellier, by stratifying copperplates with the husks of grapes, yet under various fermentation, which soon grow acid, and corrode the copper. After the plates have stood in that situation for a sufficient time, they are moistened with water, and exposed in heaps to the air. The verdigris is scraped off from their surface as it forms. Verdigris is of a bluish-green colour, it has no body, does not stand, and is only used for coarse purposes; it answers best in varnishes.

Distilled verdigris, sometimes called crystallis verdigris, is prepared from common verdigris, by dissolving it in vinegar. It is of a very bright green, and is used chiefly for varnishes, and in colouring maps, &c.

**Brown Colours.**—Bistre, is the finer part extracted from the soot of burnt wood. It is used alone for sketches in water-colours, being a transparent water colour.

Roman bistre, is a very excellent but scarce kind of bistre, imported from Rome.

Cologne earth, a mineral substance of a dark blackish brown colour, is a very useful pigment; what is generally sold in the shops for Cologne earth is an artificial mixture.

Raw umbre, a native ochreous earth, of a light brown, stands well.

Burnt umbre, is only the last mentioned colour calcined in the fire. It then acquires a rich deep brown, and is of great use, being a fine colour, that stands well.

Asphaltum, used in oil, is of a very rich deep brown. It is

a transparent or glazing colour that will not work in water, but when dissolved in turpentine, it becomes an useful substance for giving deep and spirited touches to drawings. The linens in which the Egyptians wrapped their mummies were dipped in asphaltum.

**White Colours.**—Flake white, is an oxide of lead, formed by corroding lead with vegetable acids, or vinegar.

White lead is the same as flake white, but of an inferior quality. It is the only white used in oil-painting, and is therefore a very useful colour; in water it always turns black.

Egg-shell white, and oyster-shell white, are only egg-shells or oyster-shells calcined; the animal gluten is thus destroyed, leaving the lime behind, which soon attracts the carbonic acid again from the atmosphere. Well-washed Spanish white, or common whitening, answers the same purpose.

Permanent white, is a white sold in the shops under this name, and it will not change; but great care must be employed in using it, as it is made from barytes, a deadly poison.

**Black Colours.**—Lamp black, the soot of oil, collected after it is formed by burning, is very generally used, both in oil and water, and stands perfectly well. Ivory black, the charcoal of ivory or bone, formed by giving them a great heat, while they are deprived of all access of air: it is used both in oil and water. Blue black, the coal from burning vine-stalks in a close vessel, is like ivory black, with a tint of blue.

**Indian Ink.**—The Indian ink is used in China for writing with a brush, and for painting upon the soft Chinese paper. It has been ascertained, both from experiment and information, that the cakes of this ink are composed of lamp black and size, with the addition of some perfuming substances, not essential to it as an ink. The fine soot obtained by holding a plate over the flame of a candle or lamp, and mixed up with clean size, makes an ink in every respect equal to the Chinese.

**Colouring Prints.**—Persons who wish to colour prints should wash them first with alum water, which will prevent the colour from sinking, besides giving a lustre and brightness to them. For this purpose, boil four ounces of alum in a quart of clear water, till the alum is dissolved.

COLOUR, in Physics, a property inherent in light, by which it excites different vibrations in the optic nerve, and which being sent to the sensorium, affect the mind with different sensations.

COLOURING, in Painting, the art of disposing the tints so as to produce either an imitation of the natural colours of the objects represented, or of force and brightness of effect.

COLUBER, a genus of serpents, of which there are ninety-seven species.

COLUMBA, the Pigeon, a genus belonging to the order of passerres, of which there are about seventy species, natives of different countries.

COLUMBA NOACHI, *Noah's Dove*, is one of the new constellations, situated still more to the south, directly below Lepus; and it lies on the west of Argo Navis and Canis Major, whence its place in the heavens may be easily found. There are twenty-six stars in this asterism; one of these is of the 2d magnitude, one of the 3d, two of the 4th, &c.

COLUMN, in Architecture, a round pillar, made to support and adorn a building, and composed of a base, shaft, and capital.

COLUMN, in the Military Art, a long and deep file of troops or baggage.

COLURES, in Astronomy, are two great circles passing through the poles of the world; one of them passes through the equinoctial points, Aries and Libra; the other through the solstitial points, Cancer and Capricorn; hence they are called the equinoctial and solstitial colures. They divide the ecliptic into four equal parts, and mark the four seasons of the year.

COLYMBUS, the Diver, in Ornithology, a genus of anseres, of which there are several species.

COMA, a preternatural propensity to sleep, which however the patient cannot enjoy, but wakes again immediately.

COMA BERENICES, *Berenice's Hair*. Berenice was the wife of Euergetes, a king of Egypt; and when he went upon a dangerous expedition, she vowed to consecrate her fine head of hair to Venus, if he returned in safety. Some time after the return of Euergetes, the locks, which were hung up in the

temple of Venus, disappeared, and Conon, an astronomer, publicly reported that Jupiter had made them a constellation. The cluster of stars composing Coma Berenices, is very remarkable, there being so many of the 4th and 5th magnitudes. The boundaries and contents of this asterism are: north by Canes Venatici, east by Boötes, south by Leo and Virgo, and west by Leo and Ursa Major. This constellation contains 43 stars, ten being represented of the 4th magnitude, and the remainder of less magnitudes.

**COMB**, an instrument for disentangling flax, wool, hair, &c. Combs are made of the horns of bullocks, of elephant's teeth, tortoise shell, and box or holly wood. Bullocks' horns are prepared by sawing off the tips, then holding the horns in the flame of a wood fire till they become soft. In this state they are slit open on one side, and pressed in a machine; then plunged into water, from whence they come out hard and flat. They are next sawn into proper lengths, and to cut the teeth, each piece is fixed in a tool called a clam. The teeth are cut with a fine saw, or rather a pair of saws, and they are finished with a file. The process for making ivory combs is nearly the same as the above. A method has been recently invented for cutting combs by machinery.

**COMBINATION**, in Chemistry, the union of bodies of different natures thereby producing a new compound body.

**COMBINATIONS**, in Mathematics, denote the different collections that may be formed out of any given number of things, taking a certain number at a time, without regard to the order in which they may be arranged; and are thus distinguished from *permutations*, or *changes*, which have reference to the order in which the several quantities may be disposed.

1. *When only two are combined.*—One thing admits of no combination. Two, *a* and *b*, admit of only one, viz. *ab*. Three, *a*, *b*, *c*, admit of three, *ab*, *ac*, *bc*. Four, of six, viz. *ab*, *ac*, *ad*, *bc*, *bd*, *cd*. Five, of ten, viz. *ab*, *ac*, *ad*, *ae*, *be*, *bd*, *be*, *cd*, *ce*, *de*.

Whence the numbers of combinations of two and two only, proceed according to the triangular numbers, 1, 3, 6, 10, 15, 21, &c. which are produced by the continual addition of the original series, 0, 1, 2, 3, 4, 5, &c. And if *n* be the number of things, the formula for expressing the sum of all their combinations by two's, will be  $\frac{n \cdot n - 1}{2}$ .

Thus, if  $n = 2$ ; this becomes  $\frac{2 \cdot 1}{2} = 1$ . If  $n = 3$ ; it is  $\frac{3 \cdot 2}{2} = 3$ . If  $n = 4$ ;  $\frac{4 \cdot 3}{2} = 6$ , &c.

2. *When three are combined together*, three things admit of one order, *a, b, c*. Four admit of four, viz. *abc*, *abd*, *acd*, *bcd*. Five admit of ten; *abc*, *abd*, *abe*, *acd*, *ace*, *ade*, *bcd*, *bce*, *bde*, *cde*. And so on according to the first pyramidal numbers, 1, 4, 10, 20, &c. which are formed by the continual addition of the former, or the triangular numbers, 1, 3, 6, 10, &c. And the general formula for any number *n* of combinations, taken by three's, is  $\frac{n \cdot n - 1 \cdot n - 2}{6}$ .

So if  $n = 3$ ; it is  $\frac{3 \cdot 2 \cdot 1}{6} = 1$ . If  $n = 4$ ; it is  $\frac{4 \cdot 3 \cdot 2}{6} = 4$ . If  $n = 5$ ; it is  $\frac{5 \cdot 4 \cdot 3}{6} = 10$ .

Proceeding thus, it is found that a general formula for any number *n* of things, combined by *m* at each time, is  $s = \frac{n \cdot n - 1 \cdot n - 2 \cdot n - 3}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6}$ , &c. continued to *m* factors or terms, or till the last factor in the denominator be *m*. So in six things combined by four's, the number of combinations is,  $\frac{6 \cdot 5 \cdot 4 \cdot 3}{1 \cdot 2 \cdot 3 \cdot 4} = 15$ .

3. By adding these together, the sum will be the whole number of possible combinations of *n* things, combined by two's,

three's, four's, &c. And all the series are the co-efficients of the power *n* of a binomial, wanting only the first two, 1 and *n*, therefore the sum will be  $1 \times 1^2 - n - 1$ , or,  $2^n - n - 1$ . If the number of things be five, then  $2^5 - 1 = 32 - 6 = 26$ .

4. *To find the number of changes and alterations which a number of quantities can undergo, when combined in all possible varieties of ways with themselves and each other, both as to the things themselves, and their order and position.*

One thing admits of one order or position. Two may be varied four ways, as *aa*, *ab*, *ba*, *bb*. Three quantities taken by two's, may be varied nine ways, as *aa*, *ab*, *ac*, *ba*, *ca*, *bb*, *bc*, *cb*, *cc*. In like manner four things taken by two's, may be varied 42, or 16 ways; and five things, by two's, 52, or 25 ways.

Thus also when taken by three's the changes will be  $n^3$ , and when taken by four's they will be  $n^4$ , and so generally when taken by *n*'s they will be  $n^n$ , wherefore, adding all those together, the whole number of changes or combinations in *n*, things taken by two's, by three's, by four's, &c. to *n*'s will be the sum of the geometrical series,  $n + 1^2 + n^3 + n^4 \dots n^n$ ,  $\frac{n^n - 1}{n - 1}$ .

which sum is  $\frac{n^n - 1}{n - 1} + n$ . For example, if the number of things *n* be four, this gives  $\frac{4^4 - 1}{4 - 1} \times 4 = \frac{255}{3} \times 4 = 340$ .

**COMBUSTIBLE**. A body which, in its rapid union with others, causes a disengagement of heat and light. To determine this rapidity of combination, a certain elevation of temperature is necessary, which differs for every different combustible. Combustibles have been arranged into simple and compound. The former consists of hydrogen, carbon, boron, sulphur-phosphorus, and nitrogen; besides all the metals. The latter class comprehends the hydurets, carburets, sulphurets, phosphurets, metallic alloys, and organic products.

**COMBUSTION** was defined under the word Chemistry, to be the act of a body burning in a gas capable of supporting flame. We will here treat of these supporters of combustion; and first, they have the property of shining in the dark. Various kinds of animal and vegetable substances seem to have a great deal of this kind of phosphorus; the glow-worm is a remarkable instance. Dead fish, rotten sea-weed, and numbers of insects, have this property in a great degree. Instruments for measuring the degree or intensity of light, are called photometers.

#### Effects of Light upon the Photometer.

|                                                               |       |
|---------------------------------------------------------------|-------|
| Light of the sun at an elevation of 30°, sky perfectly clear, | 75°   |
| Idem, sky white, .....                                        | 73°   |
| Light of the blue sky at an elevation of 45°, .....           | 56°   |
| Zenith, .....                                                 | 49°   |
| A cloudy sky, .....                                           | 53°   |
| A full moon, .....                                            | 34°   |
| Moon five days old, .....                                     | 20°   |
| Light from snow enlightened by the sun, .....                 | 57°   |
| — from snow in the shade, .....                               | 47°   |
| — Starry sky, March 14, 1817, .....                           | 7°    |
| — Sky clear of stars, March 14, 1817, .....                   | 7° 5' |
| Planet Venus at an elevation of 30°, April 5, 1817, .....     | 9°    |

**Simple Supporters of Combustion.**—Oxygen. For the purpose

of obtaining oxygen or any other gas, the annexed apparatus will prove the most elegant and generally useful. D is a stand with rings, supporting a retort C, and an Argand's lamp E; the latter is connected with the stand by a screw (see F); A is a pneumatic trough made of tin, and containing water, through which the gas proceeding from the retort, ascends into

the glass jar B, placed upon a wooden shelf;—as the gas ascends into the jar, the water is displaced. G is a strong tube of glass, in which gases are detonated or inflamed by electricity.

For common purposes, and where heat is not required, a matrass with a bent glass tube fitted to it, is used, as represented in the furthest figure. This may be done with a common phial and hand-basin, according to the nearest figure. A is the matrass; F the bent tube; C the phial; and D the basin.

Oxygen, is a substance known only in combination with other bodies, and has never been obtained alone. It is absorbed by combustible bodies, and converts them into acids. Oxygen is necessary for combustion, uniting itself always to bodies which burn, augmenting their weight, and changing their properties. It is necessary for the respiration of animals. It is a constituent part of atmospheric air, of water, of acids, and of all bodies of the animal and vegetable kingdoms. Combined with light and caloric, it constitutes oxygen gas. When a body has only a small quantity of oxygen united to it, not sufficient to make it an acid, it is called an oxide. Thus, most of the metals can only be reduced to the state of oxides by the addition of oxygen. This was formerly called calcination, and the metal added to oxygen was called a calx. Thus, the calx of mercury, of tin, &c. When the base has only just a sufficient quantity of oxygen to exhibit the properties of an acid, the termination *ous* is used, such as the sulphureous acid, the phosphorous acid, &c.; but when it has a greater portion of oxygen, the termination ends in *ic*, as sulphuric, phosphoric, and nitric acid.

Chlorine, is assimilated to oxygen as an elementary substance. In the gaseous state it is of a yellowish green colour, and it is this property which suggested its name. Its odour is extremely disagreeable. Chlorine is not capable of being respired; and even when mixed in very small quantities with common air, it renders it extremely pernicious to the lungs. It has never been found pure in nature; but exists in many compounds, particularly in table or sea salt.

Iodine, is obtained from sea-weeds, such as barilla and kelp: like chlorine and oxygen, when in the state of vapour, it supports combustion. Its vapour is of a violet hue: it is obtained in brown shining scales.

Fluorine, is the supposed base of fluoric acid obtained from fluor-spar; but it has never yet been obtained in a separate state.

**Combustible and Non-combustible Substances.**—Carbon. *Modern chemists consider the diamond as pure crystalline carbon.* The diamond is one of the hardest bodies known; for it resists the most highly tempered steel file, and can be ground or polished only by diamond powder. It takes an exquisite and lasting polish. It has a great refractive power; and hence its lustre, when cut into the form of a regular solid, is uncommonly great. The diamond, like other combustible bodies, burns by a strong heat, with a sensible flame, attracting oxygen, and becoming wholly converted into carbonic acid gas during that process. It combines with iron by fusion, and like common charcoal, converts it into steel. Common charcoal, the base of animal and vegetable matters, is widely diffused throughout nature. It is a compound of carbon with earths, alkalies, salts, &c. united to a portion of oxygen; it is properly an oxide of carbon. It is black, sonorous, and brittle; and is obtained from many substances, but chiefly from wood. When pure, it resists the greatest heat in close vessels. With nitrate of potash, it detonates in a hot crucible, leaving a fixed alkali behind. It does not mix with the metals, but restores their oxides to a metallic state.

Sulphur or brimstone, is a simple combustible substance, which nature frequently presents in a pure state. It is found in the earth in a loose powder, or in a solid state; and either detached or in veins. It is found also in the neighbourhood of

volcanoes, and is deposited as a crust on stones contiguous to them. It is frequently met with in mineral waters, sometimes also in coal mines, and it is found in combination with most of the metals; when united to iron, it forms *martial pyrites*, or sulphuret of iron. In order to form it into rolls, it is melted and poured into wooden moulds; it is then called roll sulphur. Flowers of sulphur are formed by subliming purified sulphur with a gentle heat in close chambers. Sulphur is a non-conductor of electricity, and hence it becomes electric by friction—it unites to most of the metals; rendering them brittle and fusible.

Phosphorus, is commonly found united to oxygen, in the state of phosphoric acid, which is found plentifully in different animal, vegetable, and mineral substances. It is a yellowish semitransparent substance, of the consistence of wax. It is luminous in the dark, at the common temperature of the atmosphere. It takes fire spontaneously, and burns rapidly in the open air, (at 122° of Fahrenheit,) with a brilliant white flame, and is converted into phosphoric acid. The combustibility and luminous property of phosphorus have given birth to various experiments, and the following will evince its characteristic properties in a pleasing manner. That phosphorus burns at the usual temperature, appears by writing with it upon black or purple paper, or any other smooth surface. The writing will be luminous in the dark, as if on fire. The fiery appearance vanishes by blowing upon it, but becomes visible again after a few seconds. The combination of any substance with sulphur, phosphorus, or charcoal *without oxygenation*, has the termination of its name in *et*; thus sulphur and iron form sulphuret of iron, phosphorus and lime form phosphuret of lime.

Hydrogen. As hydrogen gas is produced by a different process from other gases, we insert the annexed cut. C is a furnace, through which an iron tube or gun barrel, EF, passes. In this tube there is a quantity of iron filings, over which the steam of water proceeding from a retort A, placed in a large crucible V, passes, and is decomposed; the oxygen of the water combining with the iron filings, whilst the hydrogen is

set free, to pass through a vertical tube R into a gas bottle H, and from thence by the tube K into any convenient receiver. Hydrogen is one of the constituent ele-

ments of water. It is also one of the ingredients of bitumen, of oils, fat, ardent spirits, ether, and in fact of animal and vegetable bodies; it also forms a part of all animal and vegetable acids; and it is one of the bases of ammonia, and of various compound gases. It possesses so great an affinity for caloric, that it can be obtained only in the state of gas. It is consequently impossible to procure it in the concrete or liquid state, independent of combination. Hydrogen united to caloric and light, forms hydrogen gas. Hydrogen gas united to carbon, forms carburetted hydrogen gas, by which streets, shops, theatres, and churches are lighted.

Nitrogen, called also azote, is a simple body, very abundant in nature, though not producible in an uncombined state. It is one of the component parts of atmospheric air, and also of all animal and vegetable bodies, nitric acid, and ammonia. It enters into combination with light and caloric. This compound is called nitrogen gas.

Boron, is a powder of a brown colour; inodorous and insipid; electric; incombustible in covered vessels, but increases in density when the heat is augmented; insoluble in ether, oils, alcohol, and water.

Silicium, is a powder of a dark colour, incombustible at a high temperature.

COMET, an opaque, spherical, and solid body, like a planet, performing revolutions about the sun in elliptical orbits, having the sun in one of their foci. See ASTRONOMY.

COMMENDAM, a benefice or ecclesiastical living, which being void, or to prevent its becoming so, is committed *cam-*

*commendatur*, to the care of a clerk, to be supplied till a proper pastor is appointed. When a person is made a bishop, his benefice is void by the promotion; but if the king give him power to retain it, he is said to hold it in commendam.

**COMMERCE**, in a general point of view, is usually distinguished into two kinds, the commerce of import and of export; but there is little reason for this distinction, for whatever a nation imports, it must have paid an equivalent for to the country of which it is purchased, and consequently the two branches are intimately dependent, and could not exist separately for any considerable period. The value obtained in foreign markets, for the goods or manufactures which a nation exports, repays the labour of procuring or manufacturing them, with a profit to the master manufacturer and to the exporting merchant; and this value being invested in foreign produce, which on importation affords a further profit to the merchant, it is evident that the transaction, while it supports individuals, makes a real addition to the wealth of the country, by the greater value of the returns imported beyond that of the goods exported. Commerce, therefore, while it is the means of procuring a mutual interchange of conveniences between distant countries, and of extending knowledge and civilization over every part of the globe, contributes essentially to the strength and influence of the countries by which it is encouraged.

**COMMISSARY**, in the ecclesiastical Law, an officer of the bishop, who exercises spiritual jurisdiction in places of a diocese so far from the episcopal see, that the chancellor cannot call the people to the bishop's principal consistory court, without giving them too much inconveniency.

**COMMISSARY GENERAL OF THE MUSTERS**, an officer appointed to muster the army as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact state of the strength of the army.

**COMMISSARY General of Stores**, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

**COMMISSARY General of Provisions**, an officer who has the inspection of the bread and provisions of the army.

**COMMISSION**, in common Law, the warrant or letters-patent which all persons, exercising jurisdiction, have to empower them to hear or determine any cause or suit; as the commission of the judges, &c. Most of the great officers, judicial and ministerial, of the realm are made also by commission. By means of commission, oaths, cognizance of fines, answers in chancery, &c. are taken, witnesses examined, offices found, &c.

**COMMISSION of Bankruptcy**, is the commission that issues from the lord chancellor, on a person's becoming a bankrupt within any of the statutes, directed to certain commissioners appointed to examine into it.

**COMMITMENT**, in Law, the sending of a person charged with some crime to prison by warrant or order. A commitment may be made by the king and council, by the judges of the law, the justices of peace, or other magistrate, who have authority by the laws and statutes of the realm so to do.

**COMMITTEE OF PARLIAMENT**, a certain number of members appointed by the House for the examination of a bill, making report of an inquiry, process of the house, &c. When a parliament is called, and the speaker and members have taken the oaths, there are committees appointed to sit on certain days, viz. the committee of privileges and elections, of religion, of trade, &c. which are standing committees. Sometimes the whole House resolves itself into a committee, on which occasion each person has a right to speak and reply as often as he pleases, which is not the case when the House is not in a committee.

**COMMON**, is a right of privilege which one or more persons claim to take or use, in some part or portion of that, which another man's lands, waters, woods, &c. naturally produce, without having an absolute property in such lands, woods, waters, &c.

**COMMON LAW**, that body of rules received as law in England, before any statute was enacted in parliament to alter the same.—The common law is grounded upon the general customs of the realm, including the law of nature, the law of God, and

the principles and maxims of law. It is also founded on reason, as said to be the perfection of reason acquired by long study, observation, and experience, and refined by the learned in all ages. It may likewise be said to be the common birthright, that the subject has for the safeguard and defence not only of his goods, lands, and revenues, but of his wife, children, life, fame, &c. Our common law, it is said, after the heptarchy, was collected together into a body by divers of our ancient kings, who commanded, that it should be observed through the kingdom; and it was, therefore, called common law, because it was common to the whole nation and before only affected certain parts.

**COMMON PLEAS**, one of the king's courts held in Westminster Hall, wherein a lord chief justice and three puisne justices preside. In personal and mixed actions it has a concurrent jurisdiction with the court of king's bench, but has no cognizance of pleas of the crown.

**COMMONS**, in Parliament, are the lower house, consisting of knights elected by the counties, and of citizens and burgesses by the cities and borough towns.

**COMPANY**, a society of merchants, tradesmen, or others, united in one common interest. When there are only two, three, or four, thus associated, it is called a partnership; the word company being usually restrained to a considerable number of members associated by prescription or charter. The mechanics of all towns incorporated are thus formed into companies, which have charters of privileges and immunities. In London they are numerous, and many of them are very rich. In a commercial sense, the term company denotes a large association formed for the purpose of trade; thus we have the *Hamburgh company*, the oldest trading establishment in the kingdom, incorporated in 1295; the *Russia company*, confirmed by charter in 1566; the *Eastland company*, settled in 1579; the *South Sea company*, formed in the reign of Queen Anne; the *East India company*, originally established in 1606; and, lastly, the *Hudson's Bay company*, first chartered in 1670.

**COMPANY**, in the army, a body of foot commanded by a captain, who has under him a lieutenant and an ensign; the number of men from 50 to 80.

**COMPARATIVE ANATOMY**, is that which considers the bodies of other animals, serving for the more accurate distinctions of several parts, and supplying the defects of human subjects. Comparative, however, does not strictly stand in contradistinction to human anatomy; but while it embraces the whole circle of animated existence, considers man as the standard of its comparisons, and the primary object of its inquiries.

**COMPARISON**, in Rhetoric, a figure which illustrates one thing by resembling it to, and comparing it with, another, to which it has a manifest relation.

**COMPASS**, as represented in the annexed figure, an instrument employed by pilots to ascertain the ship's course at sea,

consisting of a circular box, containing a paper card. The card, which represents the horizon, is divided into 32 equal parts, by lines drawn from the centre to the circumference, called points or rhumbs; the intervals between the points are also subdivided into halves and quarters, and also the whole circumference into equal parts called degrees, 360 of which complete the circle, and consequently the

distance, or angle, comprehended between any two rhumbs, is equal to  $11\frac{1}{4}$  degrees, or 15 minutes. The four principal points are called the cardinal points, two of which, opposite to each other, are called the north and south points; that which is toward the right hand when we look north, is termed the

east, and its opposite the west point; the names of all the inferior ones are compounded of these according to their situation. Along the north and south line is fixed a small bar of steel, termed the needle, which, being touched by the load-stone, acquires a certain virtue, whereby it hangs nearly in the plane of the meridian, and consequently, determines the direction of the other points towards the horizon. This card and needle having a small socket in the centre, is supported on the point of a fine pin of steel, the whole being confined in the circular box, with a glass cover, which box is hung in gimbals to counteract the motion of the ship. A square box, with a moveable lid, serves to support the gimbals, and secures the compass from accident in removals.

The "Board of Longitude" have voted £500 to Peter Barlow, for a very simple invention of curing the local attraction of ships, by placing *abast* the compass, a plate of iron, which being regulated so as to correct the effects of the ship in any place, does the same in all places.

**COMPASSES, BEAM**, a machine to draw large circles or arcs. The beam may be any length from 2 to 6 feet, armed with two cursors of brass, one fixed and the other moveable. These cursors may be formed of points of brass, steel, pencils, &c. and the fixed cursor has sometimes an adjusting micrometer screw applied to it, for the more ready obtaining of extents.

**COMPASSES, or Pair of Compasses**, a mathematical instrument for describing circles, measuring and dividing lines or figures, &c. The common Compasses consists of two sharp-pointed branches or legs, of iron, steel, brass, or other metal, joined together at the top by a rivet, about which they move as on a centre; and are too well known to need any particular description.

**COMPASSES of three Legs, or Triangular COMPASSES**; the construction of which is like that of the common compasses, with the addition of a third leg or point, which has a motion every way. Their use is to take three points at once, and so to form triangles, and lay down three positions of a map to be copied at the same time.

**Cylindrical and Spherical COMPASSES**, consist of four branches, joined in a centre, two of which are circular and two flat, a little bent at the ends: their use is to take the diameter, thickness, or caliber of round or cylindric bodies, such as guns, pipes, &c.

**Elliptic COMPASSES**. These are used for drawing ellipses, or ovals of any kind; they consist of a beam A B, about a foot long, bearing three cursors, to one of which may be screwed any point or pencil; to the bottom of the other two are riveted two sliding dove-tails, adjusted in grooves made in the cross branches of the instrument. These having a motion every way, by turning about the long branch, go backwards and forwards along the cross; so that when the beam has gone half way about, one of these will have moved the whole length of one of the branches, and when it has got quite round, the same dove-tail has got back the whole length of the branch; and the same may be repeated on the other side. The distance between the two sliding dove-tails is the distance between the two foci of the ellipsis; so that by changing that distance, any proposed ellipse may be described.

**German COMPASSES**, have their legs a little bent outwards, towards the top; so that when shut, the points only meet.

**Hair COMPASSES**, are so contrived within side, by a small adjusting screw to one of the legs, as to take an extent to a hair's breadth.

**Proportional COMPASSES**, are those in which the joint lies, not at the end of the legs, but between the points terminating each leg. These are either simple or compound. In the former sort the centre or place of the joint is fixed; so that one pair of them serves only for one proportion. In the compound ones the joint may be set at any distance, and consequently any proportion whatever easily obtained.

**Spring COMPASSES, or Dividers**, are made of hardened steel,

with an arched head, which by its springs opens the legs; the opening being directed by a circular screw fastened to one of the legs let through the other, and worked with a nut.

**Geometry of the COMPASSES**, a species of geometry invented by M. Mascheroni, of Milan, by which all the elementary problems of plane geometry are performed by the compasses only, without the use of the ruler.

**COMPLEMENT of an ARCH or ANGLE**, is what it wants of 90 degrees; thus the complement of  $50^\circ$  is  $40^\circ$ , and the complement of  $40^\circ$  is  $50^\circ$ .

**Arithmetical COMPLEMENT**, of a logarithm, is what the logarithm wants of 10.00000, &c.; and the easiest way to find it is, beginning at the left hand, to subtract every figure from 9, and the last from 10. So the arithmetical complement of 8.2501396 is 1.7498604. It is commonly used in trigonometrical calculations, when the first term of a proportion is not radius; in that case, add together the logarithms of the 3d, 2d, and arithmetical complement of the first term, and subtract 10 from the result.

**COMPLEMENT**, in Astronomy, denotes the distance of a star from the zenith; or the arch comprehended between the place of the star above the horizon and the zenith, being the same as is otherwise called the co-latitude.

**COMPLEMENTS of a Parallelogram**, are the two smaller parallelograms made by drawing two right lines through a point in the diagonal.

**COMPLEX TERMS or IDEAS**, in Logic, are such as are compounded of several simple ones. *Complex Proposition*, is that which has at least one of its terms complex; or such as contain several members as casual propositions, or its several ideas offering themselves to our thoughts, by which we are led to affirm the same thing of different objects. Thus, neither kings nor people are exempt from death.

**COMPLEXION**, a term technically denoting the temperament, habitude, and natural disposition of the body; but popularly signifying the colour of the face and skin.

**COMPOSITION**, in Grammar, the joining of two words together; or prefixing a particle to another word, to change, or lessen, or augment its signification.—In Logic, composition is a method of reasoning, by which we proceed from a general truth to particular ones.—In Music, composition is the art of adapting sounds to airs, songs, &c. either in one or more parts, for the voice or instrument.—In Painting, composition denotes the choice and disposition of the figures of a picture.

**COMPOSITION**, in Commerce, a contract between an insolvent debtor and his creditors, by which the latter agree to take a part of the debt in compensation for the whole.

**COMPOSITION**, or *Composing*, in Printing, is the arranging of the types or letters in the composing-stick, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several pages, to make a form.

**COMPOSITION of Motion**, in Mechanics, is an assemblage of several directions of motion resulting from several powers, acting in different though not opposite directions.

**COMPOSITION of Proportion**, is the comparing the sum of the antecedent and consequent with the consequent, in two equal ratios, as, suppose  $4 : 8 :: 3 : 6$ , they say by composition of proportion  $12 : 8 :: 9 : 6$ . The same holds of the sum of the antecedent and consequent compared with the antecedent; thus we say,  $12 : 4 :: 9 : 6$ . There is a great difference between composition of proportion by addition and by multiplication. See PROPORTION.

**COMPOST**, in Husbandry and Gardening, several sorts of soils or earthy matters mixed together, to make a manure for assisting the natural earth in vegetation.

**COMPOUNDS, PRIMARY**, in Chemistry, are: 1. Alkalies, earths, oxides, acids, and compound combustibles. Secondary compounds are combinations of earths with each other, and with metallic oxides; combinations of earths with alkalies; combinations of acids with alkalies, earths, and metallic oxides; combinations of sulphuretted hydrogen with alkalies, earths, and metallic oxides; and lastly, combinations of oils with alkalies, earths, and metallic oxides.

**COMPREHENSION**, in Rhetoric, puts the whole for a part, or a part for the whole.

**COMPRESSIBILITY**, in Philosophy, that quality of a body

or fluid, by which it yields to the pressure of another body or force, so as to be brought into a narrower compass. The compressibility of water was for a long time doubted by philosophers, and the famous Florentine experiment seemed for a time to decide the question in the negative. But water is really compressible into less than its natural bulk, and is more so in winter than in summer; but with spirits of wine and oil of olives, the contrary takes place, these being most compressible in the latter season. The following table shews the quantity of compression of these fluids and mercury, when the thermometer was at 50°, and barometer 29½ inches.

| Compression of         | Millionth parts. | Specific gravity. |
|------------------------|------------------|-------------------|
| Spirits of wine, ..... | 66 .....         | 846               |
| Oil of olives, .....   | 48 .....         | 918               |
| Rain water, .....      | 46 .....         | 1000              |
| Sea water, .....       | 40 .....         | 1028              |
| Mercury, .....         | 3 .....          | 13595             |

Whence these fluids are not only compressible, but elastic; but that their degree of compressibility is not, as might have been expected, in the inverse ratio of their densities.

**COMPUTATION**, the method of estimating time, weights, measures, &c.

**CONCAVE**, an expression used to denote the curvilinear vacuity of hollow bodies.

**CONCAVE Lenses, or Mirrors**, have either one or both sides concave. See **LENS** and **MIRROR**.

**CONCAVITY**, from concave, the hollow or vacuity of bodies.

**CONCAVO-CONCAVE Lens**, is that which is concave on both sides. **CONCAVO-CONVEX Lens**, is that which is concave on one side, and convex on the other.

**CONCENTRATION**, the bringing things nearer to a centre: whence the particles of salt water are said to be concentrated by evaporating the watery part.

**CONCENTRATION**, in Chemistry, the act of increasing the strength of fluids, which are rendered stronger by abstracting a portion of the mere menstruum. This is generally effected by evaporation, where the menstruum is driven off at a lower heat than is required to drive off the substance with which it is united.

**CONCENTRIC**, having a common centre, as concentric circles, ellipses, &c.

**CONCESSION**, in Rhetoric, a figure by which something is allowed that yet might be disputed, in order to obtain another point.

**CONCHOLOGY**. The study of shells, or testaceous animals, is a branch of natural history, though not greatly useful in human economy, yet by the beauties of the subjects of which it treats, is adapted to recreate the senses, and insensibly lead to the contemplation of the glory of the Divinity in their creation. The term conchology comprehends the study of all animals which have a testaceous covering, whether inhabitants of the marine element, fresh water, or the land. Testaceology is a term synonymous with conchology, but is of later origin and application.

**CONCLAVE**, the place in which the cardinals of the Romish church meet and are shut up, in order to the election of a pope. The conclave is a range of small cells, ten feet square, made of wainscot: these are numbered, and drawn for by lot. They stand in a line along the galleries and hall of the Vatican, with a small space between each. Every cell has the arms of the cardinal over it. The conclave is not fixed to any one determinate place, for the constitutions of the church allow the cardinals to make choice of such a place for the conclave as they think most convenient; yet it is generally held in the Vatican. The conclave is very strictly guarded by troops; neither the cardinals, nor any person shut up in the conclave, are spoken to but at the hours allowed of, and then in Italian or Latin; even the provisions for the conclave are examined, that no letters be conveyed by that means from the ministers of foreign powers, or other persons who may have an interest in the election of the pontiff.

**CONCOCTION**, in Anatomy, &c. may be defined the action of fitting our daily aliment for the support and nourishment of our bodies; and also the description of all that disposition of parts and mechanism of system which unite in effecting that change in our food by which it is converted into blood, chyle,

&c. To have a clear idea of the manner in which concoction is performed, we must distinguish it into three stages: the first is performed in the progress of the aliment from the mouth down to the lacteals; which are vessels that receive the chyle from the intestines; the second is performed in the passage of the milky liquor called chyle, through the lacteal vessels to the loins, and then up under the collar bone, where it mingles with the blood; the third, or ultimate stage of concoction, is performed by the circulation of the blood and chyle together through the lungs, and the whole arterial system. In all these stages, the design seems evidently to have been to grind and dissolve the aliment, and to incorporate it with a large quantity of animal juices already prepared, and reduce it at last to the very same substance with our blood and humours.

In the first stage of concoction, by a curious configuration of parts, and action of muscles, adapted to their respective functions, our food is ground small by the teeth, and moistened by a copious saliva in the mouth. It is in the next place swallowed, and conveyed down the gullet, where it is farther mollified and lubricated by a viscid unctuous humour, distilled from the glands of that canal. From thence it slips into the stomach, where several causes concur towards its complete dissolution. It is diluted by the juices, swelled and subtilized by the internal air, and it is macerated and dissolved by the heat which it meets with in the cavity. It is also agitated and attenuated by the perpetual friction of the coats of the stomach, and the pulsation of the arteries there; by the alternate elevation and depression of the diaphragm or midriff in breathing; and by the compression of the strong muscles of the belly. After a proper stay, it is gradually propelled into the intestines, in the form of a thick, smooth, uniform, ash-coloured fluid.

When our aliment, thus prepared, arrives at the intestines, it is there mixed with three different sorts of liquors. It receives two kinds of bile; the one, thick, yellow, and extremely bitter, from the gall-bladder; the other, scarcely bitter, or yellow, but in a much larger quantity, from the liver. The third liquor that falls here upon the food, issues plentifully from a large glandular substance, called the pancreas or sweetbread, and is a limpid mild fluid, like the saliva, which serves to dilute and sweeten what may be too thick and acrimonious. The two saponaceous biles resolve and attenuate viscid substances; incorporate oily fluids with aqueous ones, making the whole mixture homogeneous; and by their penetrating and detergent qualities render the chyle fit to enter the lacteal veins, into which it is conveyed, partly by their absorbent nature, and partly by the peristaltic motion of the intestines.

If we now consider the change which our aliment has undergone, in the mouth, gullet, and stomach, together with a large quantity of bile, and pancreatic juice poured upon it in the intestines; and if we reflect also on the incessant action of the muscles, blending, churning, and incorporating the whole, we shall readily perceive, that their united agency must alter the flavours and properties of the different kinds of food, in such a manner as to bring the chyle nearer in its nature to our animal juices, than to the original substances from which it was formed. Our food, thus changed into chyle, constitutes the first stage of concoction; and we shall find the same assimilation carried on through the second.

The next stage begins with the slender lacteal veins, where they arise from the intestines by an innumerable multitude of invisible pores, through which the fine, white, fluid part of the chyle is strained or absorbed; while, at the same time, the gross, yellow, fibrous part, conveyed slowly forward, and further attenuated in the long intestinal tube, is perpetually pressed and drained of its remaining chyle, until the dregs, becoming at last useless, are ejected out of the body. These lacteal veins issue from the intestines in various directions, sometimes straight, and then oblique, often uniting and growing larger, but presently separating again. They frequently meet at acute angles, and enter into soft glands dispersed through the mesentery, from which they proceed larger than before, and more turgid, with a fine lymphatic fluid: in most places also they run contiguous to the mesenteric arteries, by whose pulsation their load is pushed forward. And thus, after various communications, separations, and protrusions, the lacteal veins pour

their chyle into a sort of cistern or reservoir formed for that purpose, between the lowest portion or the diaphragm and highest vertebre of the loins. It is very remarkable, that these veins are furnished with proper valves, which permit the chyle to move forward, but effectually stop its return; and that a great number of veins purely lymphatic, as well as the lacteal ones, empty themselves into the same cistern.

In all this contrivance it is evident, that the chyle, being more and more diluted and blended with abundance of lymph from the glands through which it passes, and from other sources, approaches still nearer to the nature of our animal juices, and consequently becomes more fit for nutrition.

The chyle is pushed from its reservoir into a narrow transparent pipe, called the thoracic duct, which climbs in a perpendicular direction by the side of the back-bone, from the loins up to the collar-bone, and opens into the subclavian vein: where, by the peculiar arrangement of several small valves, the chyle mingles gently with the blood after it has been thoroughly elaborated, and attenuated with lymph from every part of the thorax, or great cavity of the breast, and is from thence soon conveyed to the heart.

Thus we may perceive, that by a wonderful mechanism, a large quantity of chyle and lymph is forced upwards, in a perpendicular course, through a thin slender pipe; but to render this more plain, the following particulars must be attended to:—First, to the progress of the chyle, urged forward and continued from the antecedent action of the intestines, and the beating of the mesenteric arteries. Secondly, to the motion of the diaphragm and lungs, in respiration, pressing the thoracic duct that lies under them, whilst the thorax, rising and falling, resists their action, whereby the duct is squeezed between two contrary forces, and the liquor which it contains pushed upwards. Thirdly, this duct runs close by the side of the great artery, (called by anatomists, the superior portion of the descending aorta,) whose strong pulsation presses its yielding sides, and compels the chyle and lymph to mount in an upright ascent. Fourthly, it must be observed, that this duct is accommodated with valves, which permit its contents to move upwards by every compression, but never to fall back again. Thus terminates the second stage of concoction, when the chyle falls into the heart. And it may be seen, that in the progress through these two stages, our aliment has been mixed accurately with all the substances or principles which compose the blood, *viz.* saliva, mucus, lymph, bile, water, salts, oil, and spirits. The most fluid and subtle parts of our aliment, before and after it is elaborated into chyle, pass into the blood by certain absorbent veins dispersed all over the mouth, gullet, stomach, and intestines: when we consider how quickly refreshments and strength are communicated to weary, faint, and hungry people, immediately upon drinking a glass of good wine, or eating any cordial spoon-meat, this remark will appear the more obvious.

The third stage begins where the chyle mingles with the blood, and falling soon into the right ventricle of the heart, is from thence propelled into the lungs. It will appear that the lungs are the principal instruments of converting the chyle into the blood; especially if we consider their structure, first with regard to the air-vessels of which they are composed, and secondly, with regard to their blood-vessels; for we shall then clearly perceive the change which their fabric and action must produce on the chyle.

The windpipe is composed of segments of cartilaginous rings on the fore part, to give a free passage to the air in respiration; and of a strong membrane on its back part, to bend with the neck, and give way to the gullet in deglutition. This pipe is lined throughout with an infinity of glands, which perpetually distil an unctuous dense humour to lubricate and anoint the passages of the air. Soon after the windpipe has descended into the cavity of the breast, it is divided into two great branches; and these two are subdivided into innumerable ramifications called bronchia, which become smaller in their progress, (not much unlike a bushy tree inverted,) until at last they terminate in millions of little bladders which hang in clusters at their extremities, and are inflated by their admission of air, and subside at its expulsion. The clusters constitute the lobes of the lungs.

The blood-vessels of the lungs next deserve our attention. The branches of the pulmonary artery run along with those of the windpipe, and are ultimately subdivided into an endless number of capillary ramifications, which are spread like a fine net-work over the surface of every individual air-bladder; and the pulmonary vein, whose extreme branches receive the blood and chyle from those of the arteries, run likewise in form of a net over all the air-bladders of the bronchia.

From this admirable structure of the lungs, it is obvious, that the crude mixture of the blood and chyle, passing through the minute ramifications of the pulmonary artery and vein, is compressed and ground by two contrary forces, *viz.* by that of the heart, driving the mixture forward against the sides of the bronchia and air-bladders; and by the elastic force of the air equally repelling this mixture from the contrary side. By these two opposite forces, the chyle and blood are more intimately blended and incorporated; and by the admission and expulsion of the air in respiration, the vessels are alternately inflated and compressed, (and probably some subtle air or ether is received into the blood,) by which means the mixture is still farther attenuated and dissolved; and after various circulations through the lungs and heart, and the whole arterial system, is at last perfectly assimilated with the blood, being fitted to nourish the body, and answer the different purposes of animal life.

When the blood, thus prepared from the aliment, is, by repeated circulations, gradually drained of all its bland and useful parts, and begins to acquire too great a degree of acrimony, it is carried off by both sensible and insensible evacuations, through the several channels and distributions of nature. By these evacuations the body is made languid, and requires a fresh supply of aliment; while at the same time the saliva, and juices of the stomach and intestines, becoming thin and acid by multiplied circulations, vellicate the nerves of those passages, and excite hunger, as a faithful monitor, to remind us of that refreshment which is now become necessary.

**CONCORD**, in Grammar, is the same with syntax, in which the words of a sentence perfectly agree: that is, in which nouns are in the same gender, number, and case; and verbs in the same number and person with nouns and pronouns.

**CONCORD**, in Music, is the union of sounds, and is either perfect or imperfect; perfect concords consist of the fifth and eighth, the imperfect of the third and sixth.

**CONCORDANCE**. This word has been applied appropriately to a sort of dictionary of the Bible, explaining the words thereof in alphabetical order, with the several books, chapters, and verses quoted in which they are contained. Its chief use is to enable a person to find out any text of scripture, of which he is able to recollect any of the chief words.

**CONCORDAT**, a covenant or agreement with the pope concerning the acquisition, permutation, and resignation of ecclesiastical benefices. Most Catholic sovereigns have such a treaty with the pope.

**CONCRETE NUMBERS**, are those which are made to denote any particular thing, as three pounds, three guineas, &c. and are thus distinguished from abstract numbers, which have reference to no particular subject or thing, as 3, 4, &c.

**CONCRETIONS**, **MORBID**, hard substances in different parts of the animal body.

**CONDENSATION**, the act whereby a body is rendered more dense, compact, and heavy. Condensation is, by most writers, distinguished from compression, by considering the latter as performed by some external violence; whereas the former is the action of cold.

**CONDENSER**, a pneumatic engine, or syringe, whereby an uncommon quantity of air may be condensed into a given space; so that sometimes ten atmospheres, or ten times as much air as there is at the same time, in the same space, without the engine, may be thrown in by means of it, and its egress prevented by valves properly disposed. It consists of a brass cylinder, wherein is a moveable piston; which being drawn out, the air rushes into the cylinder through a hole provided on purpose; and when the piston is again forced into the cylinder, the air is driven into the receiver through an orifice, furnished with a valve to prevent its escape. See **AIR GUN**.

**CONDIMENTS.** These are not properly alimentary matters, or such as become ingredients in the composition of the animal fluid; yet they are taken with advantage along with the proper aliments, the digestion and assimilation of which they, in some degree, modify. They are of two kinds, saline or acrid; having this acrimony, for the most part, residing in their oily parts. To this list of condiments, we may add capsicum, ketchup, and soy, observing, that the whole of the seasonings consist of salt, vinegar, and aromatics, combined together; and if they are taken only in the quantity necessary to render the food more sapid, they may increase the appetite, and favour full eating; but they can hardly otherwise do harm, unless when the aromatics are taken in such large quantity as to weaken the tone of the stomach.

**CONDITION,** in Civil Law, a clause of obligation, stipulated as an article of a treaty or contract, legacy, &c. In the Common Law, condition is a restraint annexed to any thing, so that by the nonperformance the party shall sustain loss, and by the performance receive advantage.

**CONDUCTOR,** any body which receives and communicates the electric fluid.

**CONDUCTOR,** in Electricity, a term first introduced into this science by Dr. Desaguliers, and used to denote those substances which are capable of receiving and transmitting electricity; in opposition to electrics, in which the matter or virtue of electricity may be excited and accumulated, or retained. The former are also called non-electrics, and the latter non-conductors. And all bodies are ranked under one or other of these two classes, though none of them are perfect electrics, nor perfect conductors, so as wholly to retain, or freely and without resistance to transmit, the electric fluid. To the class of conductors belong all metals and semimetals, ores, and all fluids, (except air and oils,) together with the substances containing them, the effluvia of flaming bodies, ice, (unless very hard frozen) and snow, most saline and stony substances, charcoals, of which the best are those that have been exposed to the greatest heat; smoke, and the vapour of hot water. It seems probable, that the electric fluid passes through the substance, and not merely over the surfaces of metallic conductors; because, if a wire of any kind of metal be covered with some electric substance, as resin, sealing-wax, &c. and a jar be discharged through it, the charge will be conducted as well as without the electric coating. It has also been alleged, that electricity will pervade a vacuum, and be transmitted through it almost as freely as through the substance of the best conductor; but the electric spark or shock would no more pass through a perfect vacuum than through a stick of solid glass. In other instances, however, when the vacuum has been made with all possible care, the experiment has not succeeded. It has also been observed, that many of the forementioned substances are capable of being electrified, and that their conducting power may be destroyed and recovered by different processes: for example, green wood is a conductor; but baked, it becomes a non-conductor; again, its conducting power is restored by charring it; and lastly, it is destroyed by reducing this to ashes. Again, many electric substances, as glass, resin, air, &c. become conductors by being made very hot; however, air heated by glass must be excepted.

**CONDUCTOR, Prime,** is an isolated conductor, so connected with the electrical machine, as to receive the electricity immediately from the excited electric.

**CONDUCTORS of Lightning.** are pointed metallic rods fixed to the upper parts of buildings, to secure them from strokes of lightning. These were invented and proposed by Dr. Franklin for this purpose, soon after the identity of electricity and lightning was ascertained; and they exhibit a very important and useful application of modern discoveries in this science. This ingenious philosopher having found that pointed bodies are better fitted for receiving and throwing off the electric fire than such as are terminated by blunt ends or flat surfaces, and that metals are the readiest and best conductors, soon discovered that lightning and electricity resembled each other in this and other distinguishing properties; he therefore recommended a pointed metalline rod, to be raised some feet above the highest part of a building, and to be continued down into

the ground, or the nearest water. The lightning, should it ever come within a certain distance of this rod or wire, would be attracted by it, and pass through it in preference to any other part of the building, and be conveyed into the earth or water, and there dissipated, without doing any damage to the building. Many facts have occurred to evince the utility of this simple and seemingly trifling apparatus. And yet some electricians have objected to the pointed termination of this conductor, preferring rather a blunt end; because they conceive a point invites the electricity from the clouds, and attracts it at a greater distance than a blunt conductor.

**CONE,** is a solid body having a circular base, and its other extremity terminated in a single point or vertex. Cones are either *right* or *oblique*. A *Right CONE*, is that in which the right line joining the vertex and centre of the base, is perpendicular to the plane of the base; as *A B C*.

A right cone may be conceived to be generated by the revolution of the right-angled triangle *B D C*, about its perpendicular *B D*. And thus, Euclid defines a cone to be a solid figure, whose base is a circle, and is produced by the entire revolution of the plane of a right-angled triangle about its perpendicular, being called

the axis of the cone. Right cones are distinguished into classes, according to the magnitude of the angle at the vertex, made by a plane passing through that point perpendicular to the base. An *Acute-angled CONE*, is that in which the angle *A B C* is acute, or less than a right angle. An *Equilateral CONE* has its side *A B* equal to the diameter of the base *A C*. An *Obtuse-angled CONE*, is that in which the angle *A B C* is obtuse, or greater than a right angle. A *Right-angled CONE*, is that in which the angle *A B C* is a right angle.

An *Oblique CONE*, is that in which the line joining the vertex and centre of the base is not perpendicular, but oblique, to the plane of the base; as *L M N*. This solid, which is not treated of by the ancient geometers, is evidently not included in the preceding definition, that having reference to the right cone only. It has therefore been an object with the moderns to render the above more general, so as to include both cases under one and the same general definition or description, which is as follows:—If a line *V A* continually pass through the point *V*, turning upon that point as a joint, and the lower part of it be carried round the circumference *A B C* of a circle; then the space enclosed between that circle and the path of the line is a cone. The circle *A B C* is the base of the cone, *V* the vertex, and the line *V D* the axis; *D* being the centre of the circle.

**Properties of the Cone.**—1. Every cone, whether right or oblique, is equal to one-third of a cylinder of equal base and altitude. And therefore the solidity of a cone is found by multiplying the area of its base by one-third of its perpendicular altitude. 2. The curve surface of a right cone is equal to a circular sector, having its radius equal to the slant height of the cone, and its area equal to the whole circumference of the cone's base. And therefore this surface is equal to half the product of the slant side into the circumference of the base. 3. The surface of an oblique cone is not quadrable; indeed no rule has yet been found that will even lead to a practical approximation of its area, notwithstanding the attempts of several ingenious and able mathematicians. 4. The solidity of a cone with an elliptic base, forming part of a right cone, is equal to the product of its surface by a third of one of the perpendiculars, drawn from the point in which the axis of the right cone intersects the ellipse; and it is also equal to one-third of the height of the cone multiplied by the area of the elliptic base. Consequently, the above perpendicular is to the height of the cone, as the elliptic base is to the curve surface. See Dr. Barrow's "*Lectiones Geometricæ*."

**Frustum of a Cone**, is that which is formed by cutting off the upper part of a cone, by a plane parallel to its base; as the figure ABCD.

**CONES** of the *higher kinds*, are those whose bases are circles of the higher kinds; and are generated by supposing a right line fixed in a point above, though conceived capable of being extended more or less, on occasion; and moved or carried round a circle.

**CONE of Rays**, in Optics, includes all the several rays which fall from any point of a radiant, on the surface of a glass.

**CONE, or Spindle (Double)**, in Mechanics, is a solid formed of two equal cones joined at their bases. If this be laid on the lower part of two rulers, making an angle with each other, and elevated in a certain degree above the horizontal plane, the cones will roll upwards towards the raised ends, and seem to ascend, though in reality the centre of gravity is descending lower.

**CONFESSION** of an offence, is when a prisoner is arraigned, and his indictment being read, either he confesses the offence, or pleads not guilty. Confession is express or implied. Express, is where one, in open court, confesses the crime, in the most satisfactory ground of conviction. Implied, is where the defendant, in a case not capital, yields to the king's mercy, and desires to submit to a small fine, which the court may accept, without requiring a direct confession. The presumption of guilt in this case is so strong, that the defendant cannot afterwards, in a civil action, deny the trespass. Confession, previous to trial, before a justice, &c. may also be given in evidence afterwards, as against the individual confessing; but it must be voluntary, not upon promise or threats, and must be taken in time. After confession, the party may take advantage of errors in the indictment, in arrest of judgment. Confession may also be, in a civil action, and is commonly on a warrant of attorney for that purpose, which being after accompanied with a bond, is vulgarly called a bond and judgment.

**CONFIGURATION**, the exterior surface or shape that bounds bodies, and gives them their particular figure.

**CONFISCATE**, from *confiscare*, and that from *fiscus*, the emperor's treasure. Any goods which being disclaimed by another, as a felon upon trial, comes to the king, although they are the felon's own. Those which he claims as his own, are, upon conviction, not confiscate, but forfeited to the king.

**CONFLUENT**, in Medicine, an appellation given to the kind of small-pox, wherein the pustules run into each other.

**CONFORMATION**, that make and construction of the human body peculiar to every individual; whence those diseases called organical, depend upon the mal-conformation of the parts.

**CONGE D'ELIRE**, in ecclesiastical polity, the king's permission granted, under his signature, to a dean and chapter to elect a bishop.

**CONGELATION**, the transition of a liquid into a solid state, in consequence of an abstraction of heat: thus metals, oil, water, &c. are said to congeal when they pass from a fluid into a solid state. With regard to fluids, congelation and freezing mean the same thing. Water congeals at  $32^{\circ}$ ; and there are few liquids that will not congeal, if the temperature be brought sufficiently low. Every particular kind of substance requires a different degree of temperature for its congelation, which affords an obvious reason why particular substances remain always fluid, while others remain always solid, in the common temperature of the atmosphere; and why others are sometimes fluid, and at others solid, according to the vicissitudes of the seasons, and the variety of climates.

In consequence of the diminution of temperature, which is experienced as we ascend in the atmosphere, it is evident, that in every climate a point of elevation may be reached where it will be continually freezing. The altitude of the point above the surface of the earth, will depend partly on the temperature of the lower regions of the atmosphere, and partly on the decrement of heat belonging to the column at the period of observation. Thus, near the equator, it was observed by Bouguer, that it began to freeze on the sides of the lofty

mountain Pinchencha, at the height of 13,577 feet above the level of the sea, whereas congelation was found by Saussure to take place on the Alps at the height of 13,428 feet. By tracing a line on the plane of the meridian, through the points at which it constantly freezes, a curve is obtained, which has been denominated the line of *Perpetual Congelation*. The height at which this curve intersects a vertical line in the various latitudes, has been computed by Kirwan, partly from observation, and partly from the mean temperature of the parallel, and the decrement of heat, as we ascend in the atmosphere. The following table exhibits the result of his calculation; and though it is constructed on the erroneous supposition, that the mean annual temperature of the pole is  $31^{\circ}$ , which, according to the observations of Captain Scoresby and Captain Parry, must be far beyond the truth, it is tolerably accurate for the more accessible regions of the globe.

| Latitude. | Mean Height of Line of Congelation. | Latitude. | Mean Height of Line of Congelation. |
|-----------|-------------------------------------|-----------|-------------------------------------|
| 0 .....   | 15·577                              | 45 .....  | 7·658                               |
| 5 .....   | 15·457                              | 50 .....  | 6·260                               |
| 10 .....  | 15·067                              | 55 .....  | 4·912                               |
| 15 .....  | 15·498                              | 60 .....  | 3·684                               |
| 20 .....  | 13·719                              | 65 .....  | 2·516                               |
| 25 .....  | 13·030                              | 70 .....  | 1·557                               |
| 30 .....  | 11·592                              | 75 .....  | ·748                                |
| 35 .....  | 10·664                              | 80 .....  | ·128                                |
| 40 .....  | 9·016                               |           |                                     |

These numerical relations will be best perceived at a glance by means of the following diagram.

Here EP represents the rectified meridian from the equator to the pole divided into intervals of  $10^{\circ}$  each; and the different perpendiculars or ordinates at the point 0, 10, 20, &c. represent the height of the *freezing point* at the equator, and at latitude 10, 20, &c. to the pole P. The curve HP, which has a contrary flexure about  $60^{\circ}$ , exhibits the general form of the line of Perpetual Congelation from the equator to the pole.

**CONGRUITY**, in Geometry, is the same as identity, those lines and surface being congruous, which will coincide or fill the same space.

**CONGRUOUS QUANTITIES**, are those which are of the same kind, and therefore admit of comparison; and quantities which cannot be so compared, are incongruous quantities. All abstract numbers are congruous; but concrete numbers are not congruous, unless the quantities they represent be so. Thus, 3 and 4, as abstract numbers, are congruous; but if they denote 3 pounds and 4 miles, they are incongruous. Hence it follows, that the method commonly given in books of arithmetic, for stating questions in the Rule of Three, is improper; because it supposes a comparison between quantities which are incongruous. We cannot say properly, that 3 pounds : 4 men :: 6 pounds : 8 men; but that 3 pounds : 6 pounds :: 4 men : 8 men.

**CONICAL**, any thing of a conical form, or relating to the cone.

**CONICAL Ellipse, Hyperbola, Parabola**, denote those figures, under their most simple form, as cut from the cone, to

distinguish them from the same figures of a higher order. See the respective articles.

**CONICAL Ungula**, or **CONIC Ungula**, is a solid formed by a plane passing through the side and base of a cone, as the figure ECBF, fig. 1.

**CONIC Sections**, as the name implies, are such curve lines and plane figures as are produced by the intersection of a plane with a cone. From the different positions of the cutting plane, there arise five different sections, viz. a *triangle*, *ellipse*, *parabola*, and *hyperbola*. But only the three latter are particularly denominated *conic sections*. 1. If the secant, or cutting plane, pass through the vertex of the cone, and any part of the base, the section will evidently be a *triangle*, as AVB, fig. 2.

2. If the plane cut the cone parallel to the circular base, the section will be a *circle*, as ABD.

3. If the plane pass through the side and base of the cone parallel to the other side; that is, if the cutting plane make the same angle with the base as the side of the cone makes, the section is a *parabola*, as DAB, fig. 3.

4. When the plane cuts both sides of the cone, that is, when it makes with the base a less angle than the side of the cone makes, the section is an *ellipse*, as BAD.

5. When the plane passes through the side and base of the cone, making a greater angle with the base than the side or the cone makes, the section is an *hyperbola*, as DAE, fig. 4.

And if the plane be continued to cut the opposite cone, this section is called the opposite *hyperbola* to the former, as Bed, fig. 6.

6. The *vertices* of any section are the points where the cutting plane meets the opposite sides of the cone, as A and B in the preceding figures. Hence the ellipse, fig. 5, and hyperbola fig. 4, have each two vertices, but the parabola only one, unless we consider the other as at an infinite distance.

7. The *axis*, or *transverse diameter*, of a conic section, is the line joining its vertices, as AB; therefore the axis of an ellipse is within the figure, of the hyperbola without it, and in the parabola it is infinite in length, fig. 6.

8. The *centre* of a conic section is in that point which bisects the axis. Hence the centre of an ellipse is within the figure, of the hyperbola without the figure, and in the parabola it is at an infinite distance from the vertex.

The definition of the other lines, in and about the conic sections, will be found under their respective heads; and the principal properties of the different sections, under the articles **ELLIPSE**, **HYPERBOLA**, and **PARABOLA**.

The conic sections are of themselves a system of regular curves allied to each other, the doctrine of which is of the greatest use in physical astronomy, as well as in the physico-mathematical sciences, and has been much cultivated by both ancient and modern mathematicians.

**CONIUM**, **HEMLOCK**, a genus of the digynia order, in the pentandria class of plants, and in the natural method belonging to the 45th order, *umbellatæ*. There are five species. *Conium maculatum*, or the greater hemlock, grows naturally in Britain. It is a biennial plant. The stalk is smooth, spotted with purple, and rises from four to six feet, branching out at the top with decompounded leaves. The flowers are white. It is a poison-

ous plant, yet the internal and external efficacy of the hemlock has been proved in cancers, ulcers, and scrofulous tumors.

**CONJUGATE DIAMETER**, or **Axis** of an Ellipsis, is the shortest of the two diameters, or that which bisects the transverse axis.

**CONJUGATION**, in Grammar, a regular distribution of the inflexions of verbs in their different voices, moods, tenses, numbers, and persons, to distinguish them from each other.

**CONJUNCTION**, in Astronomy, the meeting of two or more stars or planets in the same degree of the zodiac.

**CONJUNCTION** may be considered as either *true* or *apparent*. When the two bodies meet in the same point of both longitude and latitude, the conjunction is *true*; when they agree in longitude, but differ in latitude, the conjunction is *apparent*.

**CONJUNCTION** is either *heliocentric* or *geocentric*.—*Heliocentric* conjunction is that which would appear to an observer at the sun; *geocentric*, that which would appear to one upon the earth.—*Geocentric* CONJUNCTIONS are either *superior* or *inferior*: thus, when a planet is seen on the same circle of latitude with the sun, but beyond him, the conjunction is called *superior*; when the planet is seen between the earth and sun, the conjunction is *inferior*.—*Grand* CONJUNCTIONS, are those wherein several of the planets are seen near together. M. de la Lande informs us, that on May 22, 1702, Jupiter and Saturn were within 1° 4' of each other; on February 11, 1524, Venus, Mars, Jupiter, and Saturn, were very near each other, and Mercury not above 16° from them; on November 11, 1544, Mercury, Venus, Jupiter, and Saturn, were within the space of 10°; on March 17, 1725, Mercury, Venus, Mars, and Jupiter, were so near each other as to be all seen through the same telescope without altering its position; and on December 23, 1769, Venus, Mars, and Jupiter, were within 1° of each other.—The Chinese have a remarkable record of a conjunction of five planets, which happened in the time of their emperor, Tehuen-hiu; who, according to the Chinese annals, reigned from the year 2514, before Christ, to the year 2436, B.C.; and which is thought to prove the great antiquity of this empire, and of astronomical science amongst these people.

**CONJUNCTION**, in Grammar, an inclinable word or particle, which joins words or sentences together, shewing their mutual relation and dependence.

**CONJURATION**, strictly means combining together by oath, especially with evil spirits to do a public harm. The using of witchcraft, conjuration, &c. was felony by 1 Jac. c. 12. but that was repealed by 9 Geo. II. c. 5, and the offences and all prosecutions for them abolished; but if any pretend to witchcraft, or conjuration, or to tell fortunes, or from skill in occult or crafty science, to discover goods or chattels supposed, they shall be imprisoned a year, and stand in the pillory once a quarter, and may be ordered to give security for good behaviour. The punishment of the pillory being abolished, they are only liable to the other penalties of the statute.

**CONOID**, a solid figure generated by the revolution of any conic section about its axis; and hence receives particular denominations, according to the section from which it is produced; as **ELLIPTICAL Conoid** or **Spheroid**, **PARABOLIC Conoid**, and **HYPERBOLIC Conoid**; for which, see the respective articles.

**CONON**, an ancient Greek mathematician, the friend of Archimedes. He was well skilled in geometry and astronomy, but is not celebrated for any particular discovery.

**CONSANGUINITY**, the relation subsisting between persons of the same blood, or who are sprung from the same root. Consanguinity terminates in the sixth and seventh degree, excepting in the succession of the crown, in which case it is continued to infinity. Marriage is prohibited by the church to the fourth degree of consanguinity inclusive; but, by the law of nature, consanguinity is no obstacle to marriage, except it be in the direct line.

**CONSCIENCE**, in Ethics, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil.

**CONSCRIPTS**, men raised to recruit the French armies. All men capable of bearing arms in France and its dependencies are registered, and when called upon by the government, are obliged to join the army on any service.

**CONSEQUENT**, is the latter of two terms of a ratio, or that

THE ENTIRE HEAVEN, SHOWN ON THE PLANE OF THE EQUINOCTIAL, AS THEY APPEAR IN NATURE.

Magnitudes of the Stars.  
 ★ 1  
 ★ 2  
 ★ 3  
 ★ 4  
 ★ 5

to which the antecedent is referred and compared; thus in the ratio  $a : b$ ,  $b$  is the consequent, and  $a$  the antecedent.

**CONSEQUENTIA**, a Latin term, commonly employed by astronomers to denote the real or apparent motion of a planet or comet, when it is moving from west to east, or according to the order of the signs; and is thus opposed to *antecedendia*, which denotes contrary motion.

**CONSIDERATION**, in Law, the material cause or ground of a contract, without which the party contracting would not be bound. Consideration, in contracts, is something given in exchange, something that is mutual and reciprocal; as money given for goods sold, work performed for wages. And a consideration of some sort or other is so absolutely necessary to the forming of a contract, that a *nudum pactum*, or agreement to do or pay any thing on one side, without any compensation on the other, is totally void in law; and a man cannot be compelled to perform it. A consideration is necessary to create a debt.

**CONSIGNMENT**, in Law and Commerce, is the sending or delivering over goods, money, &c. to another person, and is unconditional, or for a particular purpose.

**CONSISTENT BODIES**, a term partially employed by philosophers, particularly by Boyle, to denote *firm* or *fixed* bodies, in opposition to fluid ones.

**CONSISTORY**, a tribunal; every archbishop and bishop of every diocese hath a consistory court, held before his chancellor or commissary, in his cathedral church, or other convenient place of his diocese, for ecclesiastical causes. From the bishop's court the appeal is to the archbishop; from the archbishop's court to the delegates.

**CONSOLIDATION**, in Civil Law, is the uniting the possession or profit of land with the property, and the contrary. It also denotes the uniting two benefices into one.

**CONSONANCE**, in Music, is the effect of two or more sounds heard at the same time.

**CONSONANT**, a letter that cannot be sounded without a vowel before or after it. Consonants are divided into single and double; the double are  $x$  and  $z$ , the latter are all single; and these are again divided into mutes and liquids, the former are  $b, c, d, f, v, g, j, k, p, q, t$ , the liquids  $l, m, n, r$ .

**CONSPIRACY**, in Law, signifies an agreement between two or more, falsely to indict, or procure to be indicted, an innocent person for felony.

**CONSPIRATORS** are, by statute, defined to be such as bind themselves by oath, covenant, or other alliance, to assist one another, falsely and maliciously to indict persons, or falsely to maintain pleas.

**CONSTABLE**, an officer whose duty it is to preserve the peace, and to arrest all public offenders who have committed the offence in his presence, or against whom he has the warrant of a justice of the peace. There are many persons exempted by law from serving the office of constable; these are, the ancient officers of any of the colleges in the two universities, counsellors, attorneys, and all other officers whose attendance is required in the courts of Westminster-hall, aldermen of London, the president and fellows of the fellowship of physic in London, surgeons and apothecaries in London, and within seven miles thereof, being free of the company of apothecaries, and licensed teachers, or preachers in holy orders, in a congregation legally tolerated, shall be exempted from the office of a constable. The prosecutor of a felon to conviction, or the person to whom he shall assign the certificate thereof, shall be discharged from the office of constable. But generally speaking, every housekeeper, inhabitant of the parish, and of full age, is liable to fill the office of constable; he ought, however, to be of the abler sort of parishioners, as being more likely to perform his duty with probity and discretion.

**CONSTANT QUANTITIES**, in Algebra, are those whose values are known, or which remain constantly the same. These are commonly denoted by the leading letters of the alphabet,  $a, b, c$ , &c. to distinguish them from the variable and unknown quantities, which are represented by the final letters,  $z, y, x$ , &c.

**CONSTELLATION**, in Astronomy, an assemblage or system of several stars, expressed and represented under the name and figure of some animal or other emblem. The ancients portioned out the firmament into several parts or constella-

tions; reducing a certain number of stars under the representations of certain images, in order to aid the imagination and the memory, to conceive and retain their number and disposition, and even to distinguish the virtues which astrologers attributed to them; in which sense a man is said to be born under a happy constellation, *i.e.* under a happy configuration of the heavenly bodies.

The division of the heavens into constellations is probably as old as astronomy itself; at least it was known to the most ancient authors extant, whether sacred or profane. Job, chap. ix. ver. 9, "Which make  $h$  Arcturus, Orion, and the Pleiades, and the chambers of the south." By the "chambers of the south," some have understood the constellations near the south pole, which are invisible to the inhabitants of the northern hemisphere. From the manner in which Job speaks of commerce, we may infer, that he lived in a country frequented by merchants, who imported thither the rarities of the south. Job, who lived in Arabia Petraea, among the merchants, might have derived from them his knowledge of the constellations. Chap. xxxviii. 31, 32, "Canst thou restrain the sweet influence of the Pleiades, or loosen the bands of Orion? Canst thou bring forth Mazzaroth, (by which some understand the twelve signs of the zodiac,) or canst thou guide Arcturus with his sons? In the prophecy of Amos, who lived 790 years before Christ, we have the following exhortation, (chap. v. 7, 8:) "Ye who turn judgment into wormwood, and leave off righteousness in the earth; seek him that maketh the seven stars and Orion, and turneth the shadow of death into the morning, and maketh the day dark with night; that called for the waters of the sea, and poureth them out upon the face of the earth: the Lord is his name." In this passage, the seven stars and Orion are mentioned as being well known, both by Amos, who was a herdsmen of Tekoa, and the common people, to whom this exhortation was addressed; and we may hence infer, that the constellations had been invented for some time before that period. Some of the constellations are also occasionally mentioned by Hesiod and Homer, who flourished above 900 years before Christ; and Aratus of Tarsus, the astronomical poet, who lived about 277 years before Christ, in his "Phenomena," professedly treats of them all, except some few, which were invented after his time; shewing how each constellation is situated with regard to those that are near it, what position it bears with respect to the principal circles of the sphere, and what other constellations rise or set with it. See ZODIAC.

**CONSTITUTION**, an ordinance, regulation, or law made by authority of any superior, ecclesiastical or civil.

**CONSTITUTION**, physically, is that particular disposition of the body, which results from the properties and mutual actions of the solids and fluids enabling them to exercise their proper functions.

**CONSTITUTIONS**, APOSTOLICAL, a collection of regulations attributed to the apostles, and supposed to have been collected by St. Clement, whose name they likewise bear. It is the general opinion, however, that they are spurious, and that St. Clement had no hand in them. They appeared first in the fourth age, but have been much changed and corrupted since that time.

**CONSTRUCTION**, in Geometry, is the drawing those lines of a figure which are previously necessary for the making a demonstration more plain and evident.

**CONSTRUCTION OF EQUATIONS**, in Algebra, is the finding the roots of an unknown equation by the geometrical constructing of right lines or curves; or the reducing given equations into geometrical figure. And this is done by lines or curves, according to the order or rank of the equation.

**CONSUL**, is an officer established by virtue of a commission from the king, and other princes, in all foreign countries of any considerable trade, to facilitate and despatch business, and protect the merchants of the nation. The consuls are to keep up a correspondence with the ministers of England residing in the courts whereon their consulate depends. They are to support the commerce and the interest of the nation; to dispose of the sums given, and the presents made to the lords and principals of places, to obtain their protection, and prevent the insults of the natives on merchants of the nation.

**CONTACT**, in Mathematics, is when one line, plane, or body, is made to touch another, and the parts which thus touch are called the points of contact.

**CONTAGION**, in Physic, the communicating a disease from one body to another. In some diseases it is only effected by an immediate contact, as in the syphilis; in others, it is conveyed by infected clothes; and in others it seems capable of being transmitted through the air at a considerable distance.

**CONTENT**, in Geometry, is the area or quantity of matter or space included within certain limits.

**CONTIGUOUS ANGLES**, in Geometry, are those which have one leg common to each angle.

**CONTINGENT**, something casual or uncertain. Hence, future contingent, in logic, denotes a conditional event which may or may not happen, according to circumstances. *Contingent* is also a term of relation for the quota which falls to any person upon a division. *Contingent use*, in law, is that which is limited in a conveyance of lands, which may or may not happen to vest according to the contingency mentioned in the limitation of the use. A *Contingent remainder* is where no present interest passes; but the estate is limited to take effect, either to a dubious and uncertain person, or upon a dubious and uncertain event, so that the remainder may never take effect.

**CONTINUED PROPORTION**, in Arithmetic, is that where the consequent of the first ratio is the same with the antecedent of the second.

**CONTRABAND**, in Commerce, a prohibited commodity, or merchandise bought or sold, imported or exported, in prejudice to the laws and ordinances of a state, or the public prohibitions of the sovereign. Contraband goods are not only liable to confiscation themselves, but also subject all other allowed merchandise found with them in the same box, bale, or parcel, together with the horses, waggons, &c. which conduct them. There are contraband goods likewise, which, besides the forfeiture of the articles, are attended with several penalties and disabilities.

**CONTRACT**, a covenant or agreement between two or more persons with a just consideration. Contracts are either express or implied. Express contracts are, where the terms are openly and plainly uttered; implied, are those dictated by reason and justice: thus, if a man takes up goods without agreeing about the price, the law concludes, that he contracted to pay the real value.

**CONTRACTION**, or **DILATATION**, an essential property of bodies, is best learned from experiment. We see that the volume of numerous bodies is enlarged or diminished, by the application of a vast force, or else of some delicate measure; fluids may be expanded or condensed; hard substances enlarged or contracted. Thus, if a flaccid bladder be laid within the receiver of an air-pump, it will gradually swell as the exhaustion advances; but on restoring the external pressure, it will again shrink into its former dimensions.

If a tall flask, nearly filled with water, be inverted in a jar of water, and placed likewise under a pneumatic receiver, the air collected near the top of the flask will visibly expand as the operation of pumping proceeds, till it presses down the water, and begins to make its escape from below in the form of rarefied bubbles.

But air is easily compressed, by the opposite action of a syringe. In the vault or chamber of the air-gun, it is often condensed fifty or even eighty times. Nearly the half of that charge may be thrown into the pneumatic blow-pipe, from which, on partially opening the valve, it will again flow for the space of a quarter of an hour.

Other gases are likewise notably contracted or dilated, by the increase or diminution of external pressure. But liquid substances themselves manifest a similar property, though in a much lower degree. If a large glass ball, terminating in a long narrow and open stem, divided into minute spaces corresponding to the millionth parts of the whole capacity, be filled with distilled water, carefully purged of air, and introduced under the receiver of a pneumatic machine; as the exhaustion advances, the water will proportionally expand, and rise near fifty divisions; but, on admitting the atmosphere again to compress the water, it will sink to its former place in the stem.

The contraction which the water suffers, at every increase of pressure, exceeds not indeed the 20,000th part of what air would undergo in like circumstances; but it is equally real, and evinces an inherent property. Mercury treated in the same way shews a contraction three times less than water. Alcohol, ether, oils, and the various acids and saline solutions, are all condensed or expanded, though in different degrees, by the change of atmospheric pressure.

If the stem of the instrument now mentioned, were made to screw to the ball at a wide aperture, fragments of solid bodies could be easily introduced, and the vacant space filled up with water; the contraction of this portion of water being deducted from the contraction of the mixture, would give the distinct condensation of the hard materials. In this way, the compressibility of the various stones and metals could be accurately examined.

The contraction and distention produced by external or internal pressure on glass, is quite visible in a thermometer with a large bulb and very long tube. When the mercury stands near the top of the scale, it will immediately rise on reclining the tube, and will continue to flow till the thermometer has been reversed; but the mercury will again retreat, as the instrument is brought back to its vertical position. This experiment proves, that the bulb has its capacity sensibly enlarged by the thrust of the mercurial column. When long bars of wood, iron, or other metals, are laid horizontal on supports, they bend downwards by their own weight, and this depression is increased by augmenting the incumbent pressure. The upper fibres are therefore drawn into a narrower curve than those at the middle of the bar, while the under fibres are extended into a wider convexity: the particles of the former are thus contracted, and those of the latter distended. It is likewise obvious, that in this incurvation, the contraction or dilatation induced will be proportional to the thickness of the bar.

The various kinds of wood are far more compressible than water, and suffer, hence, a very considerable degree of condensation, or being let down to great depths in the ocean. Pieces of oak, ash, or elm, plunged two or three hours in a calm sea, at the enormous depth of a thousand fathoms, and then drawn up, have been found to contain four-fifths of their weight of water, and to acquire such increase of density as indicates a contraction of the wood into about half its previous volume. The specimens which have undergone this singular change, if thrown into a pail of water, will sink like a stone. Hence probably the reason, why barks lost near the shore, are afterwards discovered by their timbers breaking up and floating to the surface; while the ships which founder in the wide ocean, acquiring permanent density from the vast compression they sustain, remain motionless at the bottom, and never rise again to disclose their fate.

But pieces of wood, even of the softer kinds, whether round or square, may be easily squeezed in the direction perpendicular to their fibres, by the action of a common vice. If allowed to stand only a few minutes under that compression, and immediately thrown into water, they will sink to rise no more. If the wood be kept much longer under the vice, it will take a set, and become constitutionally denser. Even cork may, by compression, be made to sink in water; but as its texture is nearly uniform, the force must be exerted on all sides. Into a thick and very strong glass cylinder, having a syringe adapted to it, introduce a large cork ball, and inject the air by quick and powerful strokes; the ball will gradually shrivel, till it has contracted even to less than one-third of its bulk; but on allowing the charge of air to escape, the cork will speedily resume its former shape and dimensions. If the condenser be partly filled with water, on which the ball of cork is set to float, it will, under a like compression, though it has a minute portion of the liquid driven into its substance, shrink to nearly the same size as before, and soon fall to the bottom. Hence the success of the common experiment at sea, of letting down, in calm weather, to the depth of twenty or thirty fathoms, an empty corked bottle, and then drawing it up full of water, though the cork still remains in the neck. The water is not in this case forced through the pores of the cork as generally supposed, but the cork itself being condensed by the lateral

pressure of the incumbent mass, allows it to enter by the sides, and dislodge the air.

Bodies are also contracted or dilated, from the operation of some internal cause. Thus, dry air is visibly expanded by its union with moisture. If, in a warm room, the inside of a tall flask be wetted by a few drops of water, and the mouth inverted in a basin of water, the contained air, in proportion as it becomes humidified, will discharge a copious stream of bubbles. On the other hand, a notable contraction of their joint volume is produced in the absorption of water by sawdust, linen, or bibulous paper. The combination of equal measures of water and alcohol is accompanied by a contraction amounting to the fiftieth part of the whole. A similar effect results from the solution of the sulphate of soda, and other highly soluble salts.

The alliage of different metals often betrays a large contraction. The power of tin to condense copper in the composition of bronze, was even remarked by the ancients, who combined these metals in various proportions, to form their knives, chisels, or hatchets. Equal bulks of tin and copper are found to suffer a contraction amounting to not less than the fifteenth part of their whole volume.

A liquid, in joining any solid substance, commonly occasions a general contraction; but the solid itself may yet by this accession expand with prodigious force. Thus dry peas being rammed into a gun barrel, and their interstices filled with water, will in a short time burst the barrel. In like manner, if wedges of soft dry wood be driven into slits made with a saw in blocks of freestone or marble, and then have water poured upon them, these wedges will quickly swell and rend the rock. Such was the ancient mode of quarrying, before the explosive power of gunpowder came to be introduced. It is still practised in the art of cutting millstones in France, holes being bored at intervals in a line drawn across the block, and wooden plugs driven into them, and then wetted.

Hence if the side of a thin piece of wood be moistened, it will bend backwards, the humidity insinuating itself into the soft parenchymatous matter between the fibres, and therefore enlarging the circle of flexure. The thinner the wood is sliced, the greater will evidently be the incurvation produced by the wetting of its convex surface. The fibres of hair and wool, by the unequal rubbing and moistening of their sides, are made to curl up, and to condense like a clue. On this property seems to be really founded the very important process of milling, fulling, or felting, by which a raw web of woollen cloth is thickened, and its texture rendered firm and compact.

A leathern thong is extended by wetting, so are the filaments of flax and hemp; though a cord is shortened by wet, the diameter of the coil being increased, and the extension of the overlapping fibres curtailed. A sponge dipped in hot water, and drawn more than once along a rope, it will in dry weather occasion, in one hour, a contraction of one-twentieth part of the whole length,—a remarkable property often advantageously employed as a mechanical agent. But the most powerful principle of internal expansion, is the introduction of heat; whose energies vary exceedingly in different substances, but which can always be reduced to calculation, by comparing its effects with the opposite influence of external compression. Thus the same absolute portions of heat communicated to cylinders of one-inch diameter and height, of air, alcohol, water, mercury, and copper, would enable those columns respectively to sustain the weights of 10, 12, 3, and 2 pounds.

A remarkable phenomenon, of considerable importance in manufactures, obtrudes itself on our notice in this article, which is, the hardness that certain bodies acquire in consequence of a sudden contraction, and this is particularly the case with glass and some of the metals. Thus, glass vessels, suddenly cooled after having been formed, are so very brittle, that they hardly bear to be touched with any hard body. The cause of this may be thus explained: when glass in fusion is very suddenly cooled its external parts become solid first, and determine the magnitude of the whole piece, while it still remains fluid within. The internal part, as it cools, is disposed to contract still further, but its contraction is prevented by the resistance of the external parts, which form an arch or vault round it, so that the whole is left in a state of constraint; and

as soon as the equilibrium is disturbed in any one part, the whole aggregate is destroyed. Hence it becomes necessary to anneal all glass, by placing it in an oven, where it is left to cool slowly; for, without this precaution, a very slight cause would destroy it. The Bologna jars, sometimes called proofs, are small thick vessels made for the purpose of exhibiting this effect; they are usually destroyed by the impulse of a small and sharp body; for instance, a single grain of sand, dropped into them, and a small body appears to be often more effectual than a larger one; perhaps because the larger one is more liable to strike the glass with an obtuse part of its surface.

CONTRACTION, in Physics, the diminishing the extent or dimensions of a body, or the causing its parts to approach nearer to each other, in which sense it stands opposed to dilatation or expansion. Water and all aqueous fluids are gradually contracted by a diminution of temperature, until they arrive at a certain point, which is about  $8^{\circ}$  above the freezing point; but below that point they begin to expand, and continue to do so according as the temperature is lowered; and similar effects have been observed with regard to some metals.

CONTRA-HARMONICAL PROPORTION, in Arithmetic, is that relation of three terms, wherein the difference of the first and second is to that of the second and third as the third is to the first.

CONTRAVALATION, in the Military Art, is a line formed in the same manner as that of circumvallation, to defend the besiegers against the sallies of the garrison.

CONTRAVALATION, or the *Line of Contravallation*, in Fortification, a trench guarded with a parapet, and usually cut round about a place by the besiegers, to secure themselves on that side, and to stop the sallies of the garrison. See FORTIFICATION.

CONTROLLER, an officer appointed to control or oversee the accounts of other officers, and, on occasion, to certify whether or no things have been controlled or examined. In England, we have several officers of this name—controller of the king's house, controller of the navy, controller of the customs, controller of the mint, &c.

CONTUMACY, in Law, a refusal to appear in court when legally summoned, or the disobedience of the rules and orders of a court having power to punish such an offence. In England, contumacy may be prosecuted to outlawry.

CONVENTICLE, a private assembly or meeting, for the exercise of religion. The word was first attributed as an appellation of reproach to the religious assemblies of Wickliffe, in this nation, in the reign of Edward III. and Richard II., and was afterwards applied to illegal meetings of nonconformists.

CONVENTION, a treaty, contract, or agreement, between two or more parties. Every convention among men, provided it be not contrary to honesty and good manners, produces a natural obligation, and makes the performance a point of conscience. Every convention has either a name and a cause of consideration, or it has none; in the first case, it obliges civilly and naturally, in the latter only naturally.

CONVENTION, is also a name given to an extraordinary assembly of parliament, or the states of the realm, had without the king's writ; as was the convention of estates, who, upon the retreat of James II. came to a conclusion, that he had abdicated the throne, and that the right of succession devolved to King William and Queen Mary; whereupon their assembly expired as a convention, and was converted into a parliament.

CONVERGENT, or CONVERGING, the tendency of different things, variously disposed, to one common point. It is also sometimes used to denote an approximation towards the real value of a thing.

CONVERGING Lines, those which tend to a common point.

CONVERGING Rays, those which tend to a common focus.

CONVERGING Series, those series whose terms continually diminish. See SERIES.

CONVERSE, in Mathematics, commonly signifies the same thing as *reverse*. Thus, one proposition is called the converse of another, when, after a conclusion is drawn from something supposed in the converse proposition, that conclusion is supposed; and then, that which in the other was supposed, is now drawn as a conclusion from it: thus, when two sides of a triangle are equal, the angles under these sides are equal; and, on the converse, if these angles are equal, the two sides are equal.

Converse propositions are not necessarily true, but require a demonstration; and Euclid always demonstrates such as he has occasion for. An instance or two will shew this. If two right-lined figures are so exactly of a size and form (both respecting their sides and angles) that being laid one on the other, their boundary lines do exactly coincide and agree, then no one doubts that these figures are equal. Now try the converse. If two right-lined figures are equal, then if they be laid the one on the other, their boundary lines exactly coincide and agree. It is manifest that this proposition, though the converse of the former, is by no means true. A triangle and a square may have equal areas; but it is impossible the sides of the former can all coincide with those of the latter. Again, if two triangles have their sides respectively equal, their angles will also be respectively equal, by Euc. i. 8. But, if two triangles have their angles respectively equal, it does not follow that the sides will be respectively equal: this may or may not be true, according to circumstances. Converse propositions, therefore, need a proof, notwithstanding this has been termed superfluous and impertinent by Emerson and some others.

CONVERSION of Proportion, is when, of four proportionals, it is inferred that the 1st is to its excess above the 2d, as the 3d to its excess above the 4th.—CONVERSION, *Centre of*, in *Mechanics*. See CENTRE of Conversion.

CONVEX, round or curved, or protuberant outwards, as the outside of a globular body.

CONVEXITY, the exterior or outward surface of a convex or round body.

CONVEXO-CONCAVE LENS, is one that is convex on one side, and concave on the other.—CONVEXO-Convex Lens, is one that is convex on both sides.

CONVEYANCE, in Law, a deed which passes from one or more persons to others.

CONVICT, in Common Law, a person that is found guilty of an offence by the verdict of a jury. The law implies, that there must be a conviction before punishment for any offence, though it be not mentioned in any statute. On a joint indictment, or information, some of the defendants may be convicted, and others acquitted.

CONVICT *Recusant*, a person who has been legally presented, indicted, and convicted, for refusing to come to church to hear the common prayer, according to the statutes 1 and 23 Eliz. and 3 Jac. I.

CONVOCATION, an assembly of the clergy of England, by their representatives, to consult of ecclesiastical matters. It is held during the session of parliament, and consists of an upper and lower house. In the upper sit the bishops, and in the lower the inferior clergy. The convocation is now a mere form, and never enters upon business.

CONVOLVULUS, *Bind-Weed*, a genus of the pentandria class and monogynia order, in the natural method ranking under the 29th order, campanaceæ, of which there are 110 species.

CONVOY, in Marine affairs, one or more ships of war, employed to accompany and protect merchant ships, and prevent their being insulted by pirates, or the enemies of the state in time of war.

CONVOY, in Military matters, a body of men that guard any supply of men, money, ammunition, or provisions, conveyed by land into a town, army, or the like, in time of war.

CONVULSION, a preternatural and violent contraction of the membranous and muscular parts of the body.

CONUS, in Natural History, a genus of Vermes Testacea, is divided into five distinct families. There are upwards of seventy species enumerated. Many of the conus tribe are beautiful shells, and bear a high price on account of their rarity. We have no species of this genus upon the English coast. Some very curious kinds have been discovered in a fossil state in England, chiefly in the chalk cliffs of Hampshire.

COOKERY, or COOKING, the exercise of art in the preparation of food for human sustenance. It consists not only in the application of heat under various modifications and circumstances, but also in the due intermixture of condiments, calculated as well to please the palate as to promote nutrition. The exercise of this art is peculiar to man, and it has been deemed by naturalists one of his peculiar characteristics, that he is "a

cooking animal." Dr. Cullen says, that the cooking of vegetables by boiling, renders them more soluble in the stomach, notwithstanding the degree of coagulation which their juices undergo. In the second place, the application of a boiling heat dissipates the volatile parts of vegetable substances, which are seldom of a nutritious nature, but, in many cases, have a tendency to prove noxious. In the third place, boiling helps to extricate a considerable quantity of air, that, in the natural state of vegetables, is always fixed in their substance; and it is probably in this way, especially, that heat contributes to the dividing and loosening the cohesion of their smaller parts. Thus, they are rendered less liable to ferment, and to produce that flatulence which is so troublesome to weak stomachs.—In the cookery of animal substances, some practices, previous to the application of heat, are to be considered as affecting the solubility in the stomach; particularly salting and pickling. These processes are spoken of under the article CONDIMENTS.

The cookery of animal substances is of two kinds, as it is applied in a humid form in boiling and stewing; or in a dry form, in roasting, broiling, and baking. By the joint application of heat and moisture to meat in boiling, the texture is rendered more tender and soluble in the stomach; and it is only in this way that the firmer parts, as the tendinous, ligamentous, and membranous parts, can be duly softened, and their gelatinous substance rendered subservient to nutrition. Yet these effects are different according to the degree of boiling. A moderate boiling may render their texture more tender, without much diminution of their nutritious quality; but if the boiling is extended to extract every thing soluble, the substance remaining is certainly less soluble in the stomach, and at the same time much less nutritious. But as boiling extracts, in the first place, the more soluble, and therefore the saline parts; so, what remains is, in proportion, less alkaliescent, and less heating to the system.

Boiling in digesters, or vessels accurately closed, produces effects very different from boiling in open vessels. From meat cooked in the latter, there is no exhalation of volatile parts; the solution is made with great success, and if not carried very far, the meat may be rendered very tender, while it still retains its most sapid parts; and this is esteemed always the most desirable state of boiled meat. If a small quantity of water only is applied, and the heat continued long in a moderate degree, the process is called stewing, which has the effect of rendering the texture of meat more tender, without extracting much of the soluble parts. This, therefore, leaves the meat more sapid, and in a state perhaps the most nourishing of any form of cookery, as we learn from the admirable essays and experiments of Count Rumford, who found very unusual effects produced on meat, by a low degree and long continued action of heat, both in the dry and humid way.

The application of a dry heat in the cookery of meat is of two kinds, as it is carried on in close vessels, or as it is exposed to the air. The first of these which we shall consider, is baking. In this practice, meat has generally a covering of paste, by which any considerable exhalation is prevented, and the retention of the juices renders the meat more tender. In all cases, when the heat applied loosens, and in some measure extricates, the air without exhaling it, the substance submitted to this process is rendered more tender than when an exhalation is allowed. In broiling, an exhalation takes place, but as the heat of a naked fire is more nearly applied, the outer surface is in some measure hardened before the heat penetrates the whole, and thereby a great exhalation is prevented, while the whole is rendered sufficiently tender; but this kind of cookery is suited to meats that are chosen to be eaten a little raw. Nearly akin to this is the practice of frying, in which the meat being cut into thin slices, and laid in a pan over the naked fire, the heat is applied more equally to the whole substance. But as the part of the meat lying next to the bottom of the vessel would be suddenly hardened by the heat, it is always necessary to interpose some fluid matter, usually of an oily quality, as butter. A strong heat applied to the latter renders it empyreumatic, or at least less miscible with the fluids of the stomach; so that all fried meats are less easily digested than those of any other preparation. Sometimes, indeed, the same thing hap-

pens to baked meats, to which an oily matter, and that only, is added to avoid the too drying heat of the oven. It is obvious, that the preparations of stewing and frying may be frequently joined together; and according to there being more or less of the one or other, the effects may be imagined.—WATKINS' CYCLOPEDIA.

COOLER, among brewers, distillers, &c. a large vessel wherein certain liquors are cooled after having been boiled.

COOPER, in the Trades, an artificer who makes casks, tubs, barrels, and all kinds of wooden vessels, which are bound together with hoops. This is unquestionably a very ancient trade, and is referred to 2000 years ago by the writers on rural economy in Rome. Their descriptions correspond in a good measure with the construction of casks in our day. It is not known when the business of a cooper was first introduced into this country, but it has been supposed it was derived from the French. Wood used for the purpose of cask-making, should be old and thick; straight trees are the best; from these are hewn thin planks, which are formed into staves. In France, we are told, the wood is prepared in winter; the staves and bottoms are then formed, and they are put together in summer.

CO-ORDINATES, in the theory of *Curves*, signifying any absciss, and its corresponding ordinate.

COPAIBA, or BALSAM OF COPAIBA, a liquid resinous juice, which comes from the trunk of the *copaifera balsamum*. Distilled in water, it yields a quantity of limpid essential oil.

COPAIFERA, a genus of the monogynia order in the decandria class of plants, ranking in the natural method under the doubtful order. There is only one species, the *officialis*, which grows in Spanish America. Some trees do not yield any balsam, and those which do are distinguished by a ridge running along their trunks. These trees are wounded in the centre, and one of them will yield five or six gallons of balsam, but though they thrive after being tapped, they never give any more juice.

COPAL, is a beautiful white resinous substance, with a slight tint of brown. It is sometimes opaque, and sometimes almost perfectly transparent. When heated, it melts like other resins; but it differs from them in not being soluble in alcohol, nor in oil of turpentine without peculiar management. Neither does it dissolve in the fixed oils with the same ease as the other resins. When copal is dissolved in any volatile liquid, and spread thin upon wood, metal, paper, &c. so that the volatile menstruum may evaporate, the copal remains perfectly transparent, and forms one of the most beautiful and perfect varnishes that can well be conceived. The varnish thus formed is called copal varnish, from the chief ingredient in it.

COPARCENARY, in Law, an estate is said to be so held when lands of inheritance descend from the ancestor to two or more persons.

COPERNICAN System, is that system of the world in which the sun is supposed at rest; and the earth and the several planets to revolve about him as a centre, while the moon and the other satellites revolve about their respective primaries in the same manner. The heavens and stars are here supposed at rest, and that diurnal motion which they appear to have from east to west is imputed to the earth's motion from west to east. This system was asserted and taught by many of the ancients, particularly by Ecphantus, Seleucus, Aristarchus, Philolaus, Cleanthes, Samius, Nicetas, Heraclides, Ponticus, Plato, and Pythagoras; from the last of whom it was anciently denominated the *Pythagorean System*.

COPERNICUS, NICOLAS, an eminent astronomer, born at Thorn in Prussia, Jan. 10, 1472, very early discovered a great bias for mathematics, which he pursued through all its various branches; and soon acquired so great a reputation, that he was chosen professor of mathematics at Rome, where he taught for a long time with great applause. He also made some astronomical observations there about the year 1500. Returning to his own country, he began to apply his knowledge to correct the system of astronomy which then prevailed. Of all the hypotheses of the ancients, none pleased him so well as the Pythagorean, which made the sun the centre of the system, and supposed the earth to move not only round the sun, but round its own axis also. After much profound contemplation, and many careful calculations, he removed the obscurities of

this old system, and, in fact, much improved it. His discoveries and improvements he comprised in a book, printed in 1543, under the title of "*Revolutionibus Orbium Coelestium*;" and the author received a copy of it a few hours before his death, on the 24th of May 1543, he being then 70 years of age. Few works have destroyed more errors, or established more important truths, than this great work of Copernicus. His noble theory was at first coldly received, or utterly rejected; but the labours of future astronomers at length obtained it a complete triumph. Copernicus was also the first who demonstrated the double orbit of the moon; her menstrual motion about the earth, and her annual about the sun. Nor did this great man stop here: for, after laying a solid foundation of the celestial physics, he began the superstructure, by surmising a principle of attraction to be inherent in all matter. Copernicus also wrote a tract on Trigonometry; and has exhibited tokens of the versatility of his talents, as it is acknowledged that he had considerable skill as a painter, and was extremely well acquainted with the Latin and Greek languages.

COPERNICUS, the name of an astronomical instrument, invented by Whiston, to shew the motion and phenomena of the planets, both primary and secondary.

COPPER, a well-known metal, orange-coloured, nine times heavier than water, and very elastic. This fine metal, of which Great Britain produces abundance, is manufactured into numerous kinds of utensils, machinery in powder mills, sash frames, and several preparations of medicine. The oxide or rust of copper gives a beautiful green to porcelain, or glass: hence it is employed in making artificial emeralds. Copper is very abundantly used in covering the bottoms of ships. It is nearly forty years since the more intelligent among our ship-owners introduced the use of copper as sheathing for their vessels, and the advantages soon became so conspicuous, as to lead to its adoption in most cases where the circumstances of the owners were such as to admit of the expense. In the navy, the more general use of copper has formed one of the main features of the improvements of the age, but at a great expense, in consequence of the rapid decay of the article; for while in a few cases copper would be found to last ten or fifteen years, in the great majority of instances it was worn out in a third, or less than a third, of the time. The Commissioners of the Navy, anxious to lessen this source of expense, and still more the uncertainty which attaches to the duration of vessels, particularly on foreign stations, from the decay of the copper, determined that a course of experiments should be instituted, to ascertain, if possible, the cause of this remarkable difference in the quality. Application was, therefore, made to Sir H. Davy, and the council of the Royal Society, for their assistance, also to the officers of his Majesty's Mint. At the Mint the investigation was undertaken by Mr. Mushet, who, from his situation in the melting department, had great advantages, both in experience, and in the command of machinery for making experiments. He was also supplied with specimens of copper by the Navy Board, taken from the bottom of a Dutch ship, the *Batavia*, captured in the year 1798, the copper of which, after 25 years' wear, was very perfect, though considerably reduced in weight. Mr. Mushet, after engaging in this important investigation, at last brought his labours to a satisfactory close, having arrived at a knowledge of the chemical process by which durability is communicated to copper, and having taken out a patent for the newly discovered method.

COPPERAS, the green salt sulphate of iron is so named; and also the blue salt sulphate of copper is sometimes also called copperas.

COPPERED, or COPPER-BOTTOMED, sheathed with thin sheets of copper, which prevents the worm eating into the planks, or filth accumulating on the bottom, whereby a ship is made to sail heavily.

COPPER-FASTENED, the bolts and other metal work in the exterior of the bottom, made of copper instead of iron; the advantage of which is, that the vessel may afterwards be coppered without danger of the sheathing corroding the heads of the bolts; which it is found to do, if they are made of iron; and to prevent the rapid corrosion and decay of copper, on the bottoms of ships, Sir H. Davy recommends the fixing of small masses or wires of tin, or some other readily oxidable metal;

in contact with the copper sheathing, by which it is expected that the copper will be rendered so negatively electrical, that the sea water will act but slightly upon it.

**COPULA**, in Logic, the verb which connects any terms in an affirmative or negative; as riches make a man happy, where the word *make* is the copula.

**COPULATIVE PROPORTIONS**, are those wherein the subject and predicate are so joined by copulative conjunctions, that they may be severally affirmed or denied of one another.

**COPYHOLD**, in Law, a tenure for which the tenant has nothing to shew but the copy of the rolls made by the steward in the lord's court.—The customs of manors differ as much as the humour and temper of the respective ancient lords; so a copyholder by custom may be tenant in fee-simple, in fee-tail, for life, by the courtesy, in dower, for years, at sufferance, or on condition; subject, however, to be deprived of these estates upon the concurrence of those circumstances which the will of the lords, promulged by immemorial custom, hath declared to be a forfeiture, or absolute determination, of those interests; as in some manors the want of issue, in others the want of issue male, in others the cutting down timber, in others the non-payment of rent or fine. Yet none of these interests amount to freehold; for the freehold of the whole manor abides always with the lord only, who hath granted out the use of occupation, but not the corporeal seizin, or true possession of certain parts or parcels thereof, to these his customary tenants at will. If a person would devise a copyhold estate, he cannot do it by his will, but he must surrender to the use of his last will and testament, and in his will declare his intent; and here the lands do not pass by the will, but by the surrender thus made. Copyhold inheritances have no collateral qualities, which do not concern the descent, as to make them assets to bind the heir, or whereof the wife may be endowed, &c. They are not extendible in execution, but are within the acts against bankrupts, and the statutes of limitation.

**COPYRIGHT**, the right which an author may be supposed to have in his own original literary compositions; so that no other person, without his leave, may publish or make profit of the said compositions.

**CORACIAS**, *the Roller*, a genus of birds of the order of piceæ, of which there are sixteen species, though some are only supposed to be varieties.

**CORALLINA**, or **CORAL**, a genus belonging to the order of vermes zoophyta. The species are distinguished by the form of their branches, and are found in the ocean attached to stones, bones, shells, &c. The corals were formerly believed to be vegetable substances, but are now known to be only a congeries of animals. The islands in the South Seas are mostly coral rocks covered over with earth. The little creatures, which have hardly sensation enough to distinguish them from plants, build up a rocky structure from the bottom of the sea, till it reaches the surface. Some of the coralline islands are much older than others, and it is probable, that as these submarine works are continually going on, new islands may be occasionally produced.

**CORALLINES**, in Natural History, were formerly reckoned plants, but, in the Linnæan system, are placed in the class zoophyta, and defined to be submarine plants, like bodies consisting of many slender finely divided and jointed branches, or animals growing in the form of plants, having their stems fixed to other bodies, which stems are composed of capillary tubes, whose extremities pass through a calcareous crust, and open into pores on the surface. The branches are often jointed, and always subdivided into smaller branches, which are either loose and unconnected, or jointed as if glued together. They are distinguished from plants by their texture and hardness; they also yield in distillation volatile salt, and their smell when turbid resembles that of horns, and other animal substances. The corallines are distributed into the vesiculated, tubular, celliferous, and articulated winds.

**CORALS**, consist of nearly equal portions of carbonate of lime and animal matter.

**CORBELLS**, in Fortification, are baskets filled with earth, and so placed on the parapet, or elsewhere, as to leave openings through which to fire upon the enemy without being discovered.

**CORD**, **MAGICAL**, an instrument in great use among the Laplanders, and supposed to possess considerable virtues in certain magical rites and ceremonies. When properly prepared with knots, it is supposed to have power over the winds, and by means of it they will sell a favourable wind to any one that has faith enough to become a purchaser. If they untie only one of these knots, a moderate gale is to succeed; if two, it is much stronger, and if three, there is to be a storm.

**CORDAGE**, a general term for the running-rigging of a ship, as also for the rope which is kept in reserve to supply the place of such as may be rendered unserviceable.

**CORDON**, in Fortification, a row of stones made round on the outside, and set between the wall of the fortress which lies aslope, and the parapet which stands perpendicular.

**CORDWAINERS**, a term applied to the profession of shoemakers, and by which they are incorporated. The word is formed from the French *cordonnier*, and that from *cordovan*, a kind of leather brought from Cordova in Spain.

**CORIANDRUM**, **CORIANDER**, a genus of the digynia order in the pentandria class of plants, and in the natural method ranking under the 45th order umbellatæ. There are only two species, both herbaceous annuals, the leaves of which are useful for culinary and the seeds for medicinal purposes. The leaves of both species resemble those of parsley; but only one is cultivated, namely, the *sativum*, which has a small white fibrous root crowned by many parted leaves with broadish segments; in the centre is an upright branchy stalk, two feet high, having all the branches terminated by umbels of flowers, which are succeeded by globular fruit. It is propagated by seed sown in March. The seeds are carminative and stomachic.

**CORONA AUSTRALIS**, *the Southern Crown*, is an asterism interwoven with Sagittarius, and appearing like a wreath of foliage round one of the fore legs of the fabulous Centaur. There are twelve small stars in this constellation.

**CORONA BOREALIS**, *the Northern Crown*. This constellation represents a beautiful crown given by Bacchus, it is said, to Ariadne, the daughter of Minos, second king of Crete. Bacchus, continues the fable, married Ariadne, after she was basely deserted by Theseus, king of Athens; and after her death, the crown that Bacchus had given her, was made a constellation. This asterism was known to the Hebrews by the name of *Ataroth*, and by this name the stars in Corona Borealis are so called to this day in the East.

*Boundaries and Contents.*—This constellation lies between Boötes and Hercules, and is easily known by four stars,  $\alpha$ ,  $\gamma$ ,  $\delta$ ,  $\epsilon$ , forming a crescent. It contains 21 stars, of which  $\alpha$ , called also *Gemma*, is of the 2d magnitude. *Gemma* rises N. E. by N.  $\frac{1}{2}$  E. and has  $27^{\circ} 19' 39''$  of north declination, and  $231^{\circ} 46' 21''$  of right ascension. There are likewise six stars of the 4th magnitude, and the others are less in size. Meridian altitude of  $\alpha$ ,  $65^{\circ} 48' 39''$ .

**CORK**, is a substance analogous to wood; it is the exterior bark of a tree belonging to the genus oak, which grows wild in the southern parts of Europe. When the tree is fourteen or fifteen years old it is fit to be barked, and may be done successively for several years. The bark always grows up again, and its quality improves as the age of the tree increases. If the bark is not taken off in due time, it splits and peels off of itself, being pushed away by the second growth. The best bark comes from Spain and Portugal; it is taken off in sheets, care being used in keeping them as large as possible. After it is detached from the tree the Portuguese burn or char it, laying the convex side of the bark to the fire, in order to straighten and swell it. It is then piled in stacks ready for sale.

Cork is formed into soles for shoes, into corks and bungs for stopping bottles, &c. into a floatage for the nets of fishermen; it is employed generally, though perhaps with a considerable degree of error, in teaching the art of swimming; it is also ingeniously used on account of its lightness, when an amputation of the human leg has been necessary, to supply the deficiency. The Spaniards line stone walls with it, which not only renders their houses very warm, but corrects the moisture of the air; the Egyptians made coffins of it, which being covered in the inside with a resinous composition, preserved their dead bodies. It is burnt, to make that light black substance called Spanish black, from its having been first made in Spain. Cork

bark has not only been applied as above, but also in the preservation of life when in danger of shipwreck.

**CORK Fossil**, a kind of stone which is a species of amianthus, consisting of flexible fibres loosely interwoven, and resembling cork. It is fusible by fire, and forms a black glass.

**CORK Jacket**, a sort of waistcoat composed of four pieces of cork, two for the breasts and two for the back, the whole covered with canvass, with two holes to put the arms through. It was invented by Mr. Dubourg, but has been improved by Dr. Wilkinson by cutting the cork into small pieces, and quilting them between two canvass waistcoats. The most timorous may venture, with one of these on, into a rough sea.

**CORN**, the grain or seeds of plants separated from the spica or ear, and used in making bread. It is contrary to the statute to buy or sell corn in the sheaf, or otherwise than by Winchester measure.

**CORN**, in Medicine or Surgery, a hard tubercle like a flat wart, growing in several parts of the feet, especially upon the joints of the toes. This disorder is attributed to the wearing of too straight or narrow-toed shoes, which never fail to produce these tubercles, especially if the person is obliged to stand or walk much, and in the summer time. Various are the methods used for removing these callosities of the skin and cuticle; some by the knife, and others by the application of emollient and caustic, or eroding medicine.—As few things are more troublesome than corns in the feet to those who have much walking, we may observe, that the pressure may be prevented in the following manner: Take a piece of linen, spread with any emollient plaster; lay one piece over another, eight, or ten, or more times, and cut a hole in the middle of them, exactly the same size and circumference as the corn, then apply it in such a way that the corn enters the hole in the plaster, and it is thus defended against the contact of shoes and stockings.

**CORNER STONES**, in Architecture, the two stones which stand one in each joint of the chimney, commonly made of Reigate or free-stone.

**CORNET**, in the Military art, the third commissioned officer in a troop of horse or dragoons. He commands in the lieutenant's absence, his principal duty being to carry the standard near the middle of the first rank of the squadron.

**CORNET**, among the Ancients, a musical instrument resembling a trumpet used in war.

**CORNUCOPIÆ**, or **HORN OF PLENTY**, among Painters, &c. is a large horn, out of which issue fruits, flowers, &c. Upon models, the cornucopiæ is given to all deities, genii, and heroes, to mark the felicity and abundance of all the wealth procured by the goodness of the former, or the care and valour of the latter.

**COROLLARY**, a consequence drawn from something advanced or demonstrated.

**CORONATION**, the public and solemn confirming the title, and acknowledging the right of sovereignty belonging to a king or queen; at which time the prince swears reciprocally to the people, to observe the laws, customs, and privileges of the kingdom, and to act and do all things conformable thereto.

**CORONER**, an ancient officer at the common law, and so called because he acts chiefly in pleas of the crown. By statute no person can be chosen coroner unless he have land in fee in the county. The electors also must be freeholders. The coroner's duty is to inquire how any person came by an untimely death, for which purpose he issues a precept to the constables to return a competent number of persons to serve as a jury, which must consist of twelve at the least. He may commit, after inquisition, any person found guilty by the jury of murder or manslaughter, and may bind over the witnesses to give evidence. It is also the duty of the coroner to inquire of treasure that is found, who were the finders, and also who is suspected thereof. By 25 George II. the coroner shall have 20s. and 9d. a mile for the distance he shall travel to take an inquisition, paid him out of the county rates.

**CORPORAL**, an inferior officer in a company of foot, who has charge over one of the divisions, places and relieves sentinels, and keeps order in the squad to which he belongs; he also receives the word from the inferior rounds, which pass by his corps-de-garde. This officer carries a fusée, and is

commonly an old soldier: there are generally three corporals in each company.

**CORPORATION**, a body politic or incorporate, so called because the persons or members are joined into one body, and are qualified to take and grant, &c. Corporations are either spiritual or temporal: spiritual, as bishops, deans, archdeacons, parsons, vicars, &c.; temporal, as mayor, community, bailiffs, burgesses, &c. And some corporations are of a mixed nature, composed of spiritual and temporal persons, such as heads of colleges and hospitals, &c. All corporations are said to be ecclesiastical or lay: the former are either regular, as abbeyes, priories, chapters, &c. or secular, as bishoprics, deaneries, archdeacons, &c.; lay, as those of cities, towns, companies, or communities of commerce, &c.

Corporations may be established in three different ways, viz. by prescription, letters patent, or act of parliament; but they are most commonly established by patent or charter. The corporation of London is by prescription; but though corporations may be by prescription, yet that prescription did originally derive its authority by a grant from the king. A corporation may be dissolved; for it is created upon a trust, and if it be broken it is forfeited. No person shall bear office in any corporation but such as have received the sacrament, taken oaths, &c. and none are to execute in a corporation for more than a year. A corporation cannot sue or appear in person, but by an attorney. Ordinances made by corporations, to be observed on pain of imprisonment, forfeiture of goods, &c. are contrary to Magna Charta. Actions arising in any corporation may be tried in the corporation courts; but if they try actions not within their jurisdictions, and encroach upon the common law, they are liable to be punished for it. The corporation of the city of London is to answer for all particular misdemeanors committed in any of the courts of justice within the city, and for all other general misdemeanors committed in the city.

**CORPS**, in Military affairs, means a body of soldiers. *Corps de garde*, is a post in an army sometimes under cover, or in the open air, to receive a number of men who are relieved from time to time. The term is also applied to the men who watch at the post.

**CORPUS CUM CAUSA**, in Law, a writ issuing out of the Chancery to remove the body and record into the King's Bench, there to lie till judgment shall be satisfied.

**CORPUSCLE**, in Physics, a minute particle or atom, of which natural bodies are formed.

**CORRELATIVE**, something opposed to another in a certain relation, as father and son, light and darkness, motion and rest.

**CORROSION**, the action of gnawing away by degrees the continuity of the parts of bodies.

**CORROSIVE SUBLIMATE**, the old name for the chloride of mercury, called also oxymuriate of mercury, and muriated mercury.

**CORROSIVES**, in Surgery, medicines that corrode whatever part of the body they are applied to, as burnt alum, white precipitate of mercury, white vitriol, red precipitate of mercury, and lapis infernalis.

**CORRUPTION**, the destruction of the proper mode of existence of any natural body.

*Corruption of Blood*, in Law, an infection accruing to a man's state, attainted of felony and treason, and to his issue; for as he loses all to the prince, &c. his issue cannot be heirs to him, or to any other ancestor by him; and if he were noble, his heirs are rendered ignoble.

**CORSELET**, a little cuirass, or, according to others, an armour or coat made to cover the whole body, anciently worn by the pikemen usually placed in the front and flanks of the battle, for the better resisting the enemy's assaults, and guarding the soldiers placed behind them.

**CORTEX**, in Botany, the outer rind or bark of trees.

**CORUNDUM**, a mineral, of which there are two species, the perfect and the imperfect. Perfect corundum, or sapphire, is found in the East Indies, particularly in Peru and Ceylon; and it is most commonly crystallized. The general colour is blue, sometimes without colour, others red, purple, yellow, and green.

**CORUS**, a measure in Jewish antiquities, answering to the omer, containing 75 gallons 5 pints for liquids, and 32 pecks 1 pint dry measure.

**CORUSCATION**, a gleam of light issuing from any thing. It is chiefly used for the electrical fluid, when it becomes visible, as the flash of lightning, &c.

**CORVUS**, the *Crow*, one of the old constellations, lies south of Virgo, north of Hydra, east of Crater, and west of Hydra Continua. This constellation is said to have its name from the crow into which Apollo metamorphosed himself when he escaped from the giant Typhæus. Castor and Apollo were the same. Typhæus and Typhon are the same. The Crow rises in the east, when the Twins come to the meridian. Typhon was a type of the lower hemisphere; the Crow then was the symbol of the Twins, having possession of the meridian.

**CORVUS**, the raven or crow kind, a genus of birds of the order of picæ. There are 19 species, the principal of which are, 1. The corax or raven. 2. The corone or carrion crow, very much resembles the raven in form and habits. 3. The frugilegus or rook, is the corvus of Virgil; no other species of this kind being gregarious. 4. The cornix or Royston crow in its habits resembles the rook, feeding on insects, and flying in great flocks. 5. The dauricus, or white-breasted crow. 6. The monedula, or jackdaw, weighs about nine ounces. 7. The glandarius, or jay, is one of the most beautiful of British birds. 8. The caryocatactes, or nut-cracker, is less than the jackdaw, the general colour of the body is of a rusty brown, and the wings are black, with white spots. These birds seldom visit England, but abound in Germany. 9. The pica, or magpie, in its manners approaches near to the crow, feeding both on animal and vegetable food. 10. The graculus, or red-legged crow, is of a slender make, active and thriving, much taken with glitter, and apt to catch up lighted sticks, whereby it has been even known to set houses on fire. It is found in Cornwall, North Wales, and Scotland. 11. The cristatus, or blue jay, is smaller than the common jay. This species is peculiar to North America. 12. The Canadensis is a small bird, the general colours of which are yellow-white, blackish-brown, and a pale ash. These birds inhabit Canada and Hudson's Bay, where they are called whiskijohn and whiskijack.

**CORYLUS**, the *Hazel*, a genus of the polyandria order, in the monocæia class of plants; which in the natural method ranks under the 60th order, amentaceæ. There are three species, all of the shrub kind, having several varieties, valuable for their nuts, and their usefulness in copses and hedges. The wood is useful for poles, hoops, spars, handles, fishing rods, &c. A kind of chocolate has been prepared of the kernels of the nuts; and the oil expressed from them is used by painters and chemists.

**COS**, the *Whetstone*, a genus of vitrescent stones, of which there are several kinds, some consisting of rougher, and others of smoother particles; and used not only for whetstones, but also for mill-stones and other purposes.

**COS-TURCIA**, Turkey Stone, a species of stones of the garnet kind, and of the siliceous class. It is of a dull white, and often of an unequal colour. It strikes fire with steel, and effervesces with acids. It is used as a whetstone, and those of the finest grain are the best hones for cutting tools, razors, lancets, &c.

**COSMETIC**, in Physic, any medicine or preparation which renders the skin soft and white, or helps to beautify and improve the complexion, as lip-salves, cold creams, ceruss, &c.

**COSMICAL**, an astronomical term for one of the poetical risings of a star; thus a star is said to rise cosmically when it rises with the sun.

**COSMOGONY**, the science of the formation of the universe; or that which discusses the particulars of the creation of the world.

**COSMOGRAPHY**, a description of the several parts of the visible world; or the art of delineating the several bodies, according to their magnitudes, motions, &c. It consists of two parts—geography and astronomy.

**COT**, in Naval affairs, a particular sort of bed-frame, suspended from the beams of a ship, for the officers to sleep in. It is made of canvass, sewed in the form of a chest, about six feet long, one foot deep, and two or three wide, and is extended by a square wooden frame, with a canvass bottom, on which the bed or mattress is laid. It is reckoned much more convenient at sea than either the hammocks or fixed cabins.

**COTTON** is the produce of the gossypium, a plant about the size of a currant bush, a native of the torrid zone, though it is produced in parts of Turkey, so far as 44 or 45 degrees from the equator. The finest cotton is known by the name of cat's-claw, from its singular appearance when it breaks the pod. This kind was accidentally discovered at the island of Bourbon, and was supposed to have been introduced among some seed sent from South America to the Mauritius. The soil should be extremely well prepared, and of the best quality, for the reception of cotton seed, which is usually sown in November or December, after the periodical rains in tropical climates, and ripens in May or June; when the numerous pods, which are about the size of large gooseberries, break, and display their downy contents. These are picked, and after the husks have been disengaged, the cotton is put into a small mill, consisting of two bright steel rollers, each about an inch in diameter, set parallel within the distance of about the 20th part of an inch. These rollers move different ways, and draw the cotton through between them, while the seeds are forced out of the respective little balls of down in which they are enclosed, and drop into a bag. The generality of cotton is white; but some is of a nankeen colour, and is invaluable in the manufacture of that article, as it fades very little, even with long use and frequent washing. The elasticity of cotton is inconceivable! It may be pressed into a 50th part of the space into which the strongest packers can reduce it by personal exertion: large screws are erected at many sea-ports where cotton is shipped, for the purpose of bringing the bales into the smallest compass, so as to save freight. Cotton can only be imported as a raw material, in which form it comes to us from the Levant, the West Indies, America, and the East Indies. In the last quarter, there are some kinds indigenous, but some are exotics. It is a highly dangerous cargo, being very subject to take fire if at all damp when packed, or if the smallest spark should reach it; in either case, it will burn very slowly for weeks; but when the hold is opened, and air supplied, bursts forth with inconceivable fury. There is a species of silky down produced in pods, (similar to those of the cotton plant,) on a very large tree, called the seemul. It is only fit to fill beds. Specimens of it have passed through various hands; but this kind of cotton is so peculiarly glossy, and the fibre so short, that it could neither be carded nor spun. When mixed with rabbit's fur, &c. to make hats, it is always separated. It also failed in paper-making; otherwise its abundance and cheapness would have rendered it highly important.

**COTTON Manufacture**, in Commerce, is now one of the most important branches of British industry. **Cotton Spinning**, the process of reducing cotton wool into yarn or thread. The method formerly used for this purpose was by the hand, upon a machine called a one-thread wheel. But about 1767, Mr. Hargrave, an operative weaver of Lancashire, made a machine, by which a great number of threads might be spun at once, and for which he obtained a patent. This is called a jenny, and with it, one person can spin 100 hanks in a day; each hank containing 840 yards.

**Carding of COTTON**, as a preparation for spinning, used formerly to be performed by the hand, with a single pair of cards on the knee, but this being a tedious method, and ill adapted to the rapid operations of the spinning machines, new ways were contrived. The first improvement was by Mr. Hargrave, and consisted in applying two or three cards to the same board, and fixing them to a stool or stock; with these, one woman could perform three times as much as by the common way. But a more expeditious method is by the cylinder cards, to the invention of which several persons lay claim. The next great improvements in the cotton manufacture were from Mr. (afterward Sir Richard) Arkwright, of Cromford, in Derbyshire. He obtained a patent for his new system of spinning cotton in 1769, and in 1775 another, for engines to prepare the materials for spinning. The validity of this second patent was set aside in 1781, but in 1785 he obtained a verdict that established the sufficiency of his patent. In the same year, however, he was cast in another trial, on the ground of his not being the original inventor of that simple and beautiful contrivance the *Twist* or *Water Frame*. Arkwright still persevered in declaring himself the inventor, and on the 10th of November, 1785, he moved, in

the court of King's Bench, for a new trial; but his rule was refused; and on the 14th of November, 1785, the court of King's Bench gave judgment to cancel the letters patent. It may be proper to observe, that Sir R. Arkwright's contests with the rival manufacturers of Lancashire, related chiefly to the operation of carding. The Annual Register for the years 1781 and 1785, or the Gentleman's Magazine, probably contains faithful records of all these trials, rules, and issues.

The result of Arkwright's inventions is a combination of machinery, by which cotton is carded, wove, and spun with the utmost exactness. To these improvements, the country is indebted for the great extent of its cotton manufactures; large works having been erected in England and Scotland, many containing several thousand spindles, driven by large water-wheels, some of such extent as to spin at the rate of 1000 yards of twist in a minute. Another machine has been invented, called a mule, because it is a kind between Mr. Hargrave's and Mr. Arkwright's. This also promises to be of great use in spinning cotton yarn for muslins to a degree of fineness equal to those of India. See MILL.

The operations which cotton undergoes in its passage from the raw material to the state of thread, are various and multiplied in proportion to the fineness required, and the different uses to which it is destined. If we analyze these operations, they resolve themselves into the following: Batting, carding, doubling, drawing, and twisting. The three latter are never performed singly, but are variously joined in the same machine; and the same elementary processes are oftentimes repeated in different machines, with various and different effects. With reference to these effects, the operations which cotton undergoes, may be denominated batting, carding, drawing, and doubling, roving, and spinning.

*Batting*, is that operation which prepares the cotton for carding, by opening and disengaging the hard compressed masses in which it comes from the bales. It is performed by beating the cotton with sticks on a square frame, across which are stretched small cords, about the thickness of a goose quill, with intervals sufficient to suffer the seed, leaves, and other adventitious matter, to fall through. When a hard matted or compressed mass of cotton is smartly struck with a stick, the natural elasticity and resiliency of its fibres, gradually loosen and disengage them, and the cotton recovers by repeated strokes all its original volume. During this operation the seeds, &c. which adhere, are carefully picked out by the hand, and the cotton rendered as clean as possible. Batting is generally and best performed by hand, though the scarcity of hands and cost of labour have rendered other contrivances necessary.

*Carding*, is that operation in which the first rudiments of the thread are formed. It is performed, as we have before stated, by cylinders covered with wire cards, revolving with considerable swiftness in opposite directions, nearly in contact with each other, or under a kind of dome or covering, the under surface of which is covered with similar cards, whose teeth are inclined in a direction opposite to those of the cylinder. By this means the separation of almost every individual fibre is effected, every little knotty or entangled part disengaged, and the cotton spread lightly and evenly over the whole surface of the last or finishing cylinder, from which it is stripped by the contrivance we have already described.

For jenny spinning, which is still in use for the coarser kinds of thread, the cardings are stripped off in separate lengths. The finishing cylinder is covered with the ordinary cards nailed on in stripes across, and the cotton contained between the margins or intervals of each stripe, forms one carding, whose length of course depends on the width of the engine, or cylinder. When stripped off by the crank and comb, it forms a loose and shapeless film, which falling on the surface of a plain wooden cylinder, the lower half of which revolves within a hollow shell or casing, the cotton in its passage is rolled up and delivered at the other side in perfect and cylindrical cardings.

For mule or water spinning, the finishing cylinder is covered with spiral or fillet cards, and the cotton being taken off in one continued fleece, and contracted by passing through the funnel and rollers, forms one endless and perpetual carding, which is

interrupted only, or broken, when the tin can that receives it is completely filled.

In the jenny carding, the fibres of the cotton are disposed across or at right angles to the axis of the carding; in the perpetual carding they are disposed longitudinally, or in the direction of its length, and it is this circumstance which renders the carding destined for mule or water spinning, inapplicable to the jenny, and *vice versa*.

*Drawing*, and *Doubling*, is one of the preparatory processes for which we are indebted wholly to Sir Richard Arkwright, and belongs exclusively to the mule, or water spinning. The doubling, or passing three or four cardings at once through a system of rollers, by which they are made to coalesce, is intended to correct any inequalities in the thickness of the cardings, and also to admit of their being frequently drawn out or extended by passing through the rollers. The effect of this frequent drawing is to dispose the fibres of the cotton longitudinally, and in the most perfect state of parallelism. The operation of carding effects this in a certain degree; yet the fibres, though parallel, are not straight but doubled, as may easily be supposed from the teeth of the cards catching the fibres sometimes in the middle, which become hooked or fastened upon them. Their disposition is also farther disturbed by the taker-off or comb, which strips them from the finishing cylinder; and though the general arrangement of the fibres of a carding is longitudinal, yet they are doubled, bent, and interlaced in such a way, as to render the operation we are now speaking of absolutely necessary. When the cardings have been passed four or five times through the drawing frame, every fibre is stretched out at full length, and disposed in the most even and regular direction; and though the average length of a fibre of cotton is not two inches, yet the finished drawing, as these prepared cardings are now termed, has all the appearance of a lock of Jersey wool, whose fibres, six or eight times as long as those of cotton, have been carefully and smoothly combed.

*Roving*, is that operation by which the prepared cotton, as it comes from the carding engine, or drawing frame, is *twisted* into a loose and thick thread, and wound upon a spindle or bobbin.

In jenny spinning, the cardings are roved without any other preparation, by a machine called a roving billy; for a description of which, with other particulars relative to jenny spinning, see JENNEY.

In mule or twist spinning, the prepared carding or drawing, as it is termed, is again passed through a system of rollers, and is twisted, either by a rapidly revolving can, into which it is delivered from the rollers, or by a fly and spindle similar to those of the flax wheel; in the latter case it is wound on the bobbin by the machine; in the former, it is received in the conical can in which it acquires the twist, and is afterwards wound upon bobbins by the smaller children of the mill.

Sir Richard Arkwright always employed the revolving can, and it is still employed in many of the first mills in the country. The roving frame with fly and spindle, which is in fact nothing more than the twist frame of Sir Richard, is now however very generally in use, especially since later improvements have removed objections to the machine, which rendered its use heretofore inconvenient. See FRAME.

The operations through which the thread passes after it has received the first twist are various, and depend greatly on the use it is intended for. The finer it is required, the oftener it is drawn out and twisted, till by degrees, as in the process of wire-drawing, it is brought down to the fineness required. The rovings are therefore distinguished into first, second, and third, according to the number of operations they have gone through.

*Spinning*, is the last operation which the thread undergoes in the series of processes employed in converting it into thread, and is that in which it receives the final extension and twisting. It is performed either on the jenny, twist frame, or mule.

The thread is of two kinds, *viz.* *twist*, so called from its being harder twisted than the other, forming a stouter thread, and used for the web or warp of piece goods; and *weft*, which is a looser, softer thread, and used for the woof. The weft is delivered to the weaver in small oblong rolls called *cops*, in the state they are stripped off the spindles of the mule or

jenney. When these are used, a small pointed piece of wood or skewer is carefully passed through the axis of the cop into the place formerly occupied by the spindle, and one end of it being held between the teeth, the thread is wound off the cop upon the weaver's bobbin by a wheel somewhat smaller in size, but the same in principle as the common one-thread wheel, on which all the spinning was formerly performed. This is generally done by children, and the bobbins are then ready for the shuttle. Twist undergoes several operations before it is ready for the loom. It is delivered by the spinner either in hank or cop.

Hank twist is that which is spun on the water frame, from the bobbins of which it is reeled into hanks of a determinate length, each measuring 840 yards. The value and fineness of the thread are proportionate to the number of hanks in a pound, and they are denominated by numbers, as Nos. 20, 50, 100, &c. which express the hanks which a pound of twist contains. In this state it is generally *sized*, an operation which is intended to give additional strength and tenacity to the thread, and enable it to support the different operations in its passage to the loom. It consists in impregnating the thread fully with thin size, chiefly formed of wheat flour boiled in water, with the addition of a little glue. The twist is carefully worked in this, and afterwards wrung and dried. The thread acquires considerable strength by this operation, and the loose fibres are all firmly attached or glued to its surface. It is then delivered to the winder.

*Winding*, is that operation by which the thread is transferred to the warping bobbin, either from the cop, hank, or twist frame bobbin.

Formerly this was chiefly done by females, and the work was carried home and performed by any of the family not engaged in domestic concerns, on a small wheel that turned two bobbins at a time. This mode is still in use, but the work has been greatly abridged and facilitated by the use of machines of various constructions.

Cop twist is that which is spun on the mule or jenney. It is reeled only occasionally, to ascertain its value and fineness, and is delivered in cops to the winder.

The next operation is that of *warping*, or the formation of the web. The machine on which this is performed is an octagonal prism five or six feet high, and somewhat less in diameter, revolving vertically, and put in motion by a band and pulley placed under the seat of the warper. The bobbins which furnish the thread are suspended horizontally in a frame on one side. Twenty-eight or thirty threads, forming together a system called a *half beer*, are wound round the prism in a spiral form from top to bottom. The machine is then turned the contrary way, and the thread wound round the prism upwards from bottom to top, and this is repeated backwards and forwards till a sufficient number of *half beers* have been wound to form a web of the breadth required. When finished, and the ends properly secured, the whole is wound off and coiled upon the hand into a round ball called the *warp*. If the thread has been previously sized in the hank, it is now ready for the loom, but if the warp is made of cop twist, that operation is next performed.

The warps are boiled several hours in water till they are thoroughly penetrated and softened; after draining some time they are then uncoiled and worked in the size till fully impregnated, after which the superfluous size is squeezed out, and they are suspended on poles to dry: the warp is then ready for the loom.

Without this operation of sizing, which, as we have before observed, gives strength and tenacity to the thread, it would not support the friction of the loom. Two threads are passed between each dent of the reed, and at each stroke of the treadle one ascends whilst the other descends. There is therefore a constant friction of the threads upon each other, as well as against the teeth of the reed. The motion of the reed itself also backwards and forwards, and of the healds up and down, is very severe upon the warp, and unless it has been well penetrated by the size, and its fibres well cemented or glued together, this continual rubbing is sufficient to destroy its texture.

Good sizing prevents this, but it is still further aided by

another operation called *dressing*, which is performed by the weaver himself, after the warp is got into the loom. This consists first, in applying with a brush a kind of paste made of wheat flour well boiled, to which is often added a small portion of common salt; sometimes of potash, and sometimes even a little tallow. It is in fact a repetition of the operation of sizing, with this difference, that the dressing is applied chiefly to the surface of the thread, which is slightly smeared with the paste, and brushed uniformly in one direction from the healds to the beam, by which means the loose fibres are all disposed evenly one way, and firmly glued fast to the thread.

In summer the warp is dried simply by fanning it, but in winter, and in damp cold weather, a hot iron is lightly passed over it. It is then dressed again with a brush dipped in tallow or butter, with which it is slightly greased. This gives suppleness and smoothness to the thread, and greatly diminishes the friction of the healds and reed. As such a portion of the warp as is extended between the healds and beam can alone be dressed at one time, this is woven, and the dressing repeated again upon another portion, and so on, alternately dressing and weaving till the whole of the web is finished.

Various improvements on these different processes have taken place of late years, which have made greater or less progress in proportion to their utility and importance. We shall enumerate, therefore, not only those of recent date, but such as, though known some time, have not been generally adopted.

The weaver's bobbin is still wound by hand in the manner already described, though the use of a small machine, by which twenty bobbins or upwards are wound at once, is daily gaining ground. They are to be seen now in almost every weaver's cottage where several looms are employed. This labour is further abridged by a very ingenious contrivance, for which a patent has been obtained. The cops, instead of being wound, are compressed or squeezed till they are small enough to enter the shuttle. The winding here is done away, and the cops thus compressed are preferred by the weavers to the common bobbin. In those large establishments where the different processes, such as spinning and weaving, are carried on together, the cops are spun small enough to enter the shuttle without compression. The weft is transferred at once from the spindle of the mule to the weaver's shuttle, and the time and waste of winding, and even of compressing, saved entirely.

On the same principle also, a considerable reduction has been made in the labour of reeling and winding twist. Till within a late period, the practice has uniformly been to reel it into hanks from the bobbin it was spun on, to size it in the hank, and then wind it for warping. An obvious reduction of this labour is to warp it directly from the bobbin it is spun on, and size it in the warp like cop twist. For reasons, however, which it will not be necessary here to enter into, this has been found impracticable. It is, however, transferred to the warping bobbin, without the intermediate labour and waste of reeling, and the sizing is done in the warp. Considerable improvements in the mode of sizing have been made within these few years, especially in the sizing of warps.

Formerly, the practice was to work the warp in the warm size by the hand, the heat of which was of course limited to that degree which could be readily borne by the workman. Experience having proved, that the hotter the size, the more evenly and perfectly was the warp penetrated, various contrivances were adopted for applying it at a high temperature. Amongst others, are oblong troughs furnished with several pairs of rollers, through which the warp passes, and is strongly compressed whilst immersed in the hot size. Mr. Marsland's idea of placing the twist in an exhausted receiver, and admitting the hot size, promises considerable advantages in some cases, and when the plan has been matured, will no doubt be susceptible of many applications.

But the greatest improvement that has been made in these different processes, and one that must eventually effect a complete revolution in the whole system, is Messrs. Ratcliffe and Ross's mode of dressing. Hitherto this operation has been performed by the weaver in the manner we have already described, at the expense of one-third of his time and labour. As it is only possible for him to dress at once as much of the work

as is contained between the healds and beam, he is scarcely got settled to his work, after each operation, before he is again called off to dress another portion. By this continual interruption of one species of labour by another totally different, it must be obvious to every one, that not only much time is lost, but that the labour itself cannot be equally well performed.

There is a delicacy and certainty of touch in weaving, dependent on long habit and experience, and on which the evenness and goodness of the cloth depends. If the force with which the woof or weft is driven up by the reed, be not always alike, if it is greater at one time and less at another, the cloth will be thicker and thinner at those places, and such is the nicety on which this depends, that the most experienced weaver, after an interruption of some hours, cannot at once regain it.

Messrs. Ratcliffe and Ross dress the whole of the warp before it is wound upon the beam, the labour of the weaver is therefore uninterrupted, and his attention directed solely to one object. This alone is a great point gained, but it is attended also by other, not less important, advantages. Great part of the intellectual skill required in weaving is in the dressing and beaming of the warp; the mere mechanical part of throwing the shuttle, &c. is soon acquired, even by a boy. A more accurate division of labour, by reducing the beaming and dressing to a system by which they are better, more economically, and more expeditiously performed than before, has removed the great difficulty in the art of weaving, and rendered it in a great measure the employment of children.

From what we have already said, it will appear that the object in dressing and sizing is nearly the same, and Messrs. Ratcliffe and Ross, by this improved mode of dressing, have succeeded in reducing these operations to one. They have gone one still further; they have done away the necessity of warping, by forming the web at once from the bobbin, and thus reduced the warping, sizing, dressing, and beaming, to one operation. A thousand bobbins and upwards supply the materials for the warp, which in its progress is properly disposed and arranged, sized, dressed, and finally wound upon the beam. This improvement, which may justly be regarded as the most important that has taken place in weaving, since the invention of the fly shuttle fifty years ago, must in the end effect a complete change in the system of labour. Great however as its advantages are, some time must necessarily elapse before it can be accommodated to general use. In large establishments, where the different processes of the manufacture are carried on together, such as spinning, weaving, and the labour immediately connected with them, it has been adopted with the happiest success, but the weaving in this country is chiefly done in the cottages of the poor, and to their use the costly and bulky apparatus of Messrs. Ratcliffe and Ross is not adapted.

To derive all the advantages possible from this improvement, therefore, it will be necessary either that the weaving be done in large shops, to each of which a dressing machine may be attached, or that the warps be delivered to the country weavers ready dressed and wound upon the beam. The former plan is daily gaining ground, and perhaps it is not difficult to foresee, that at no very distant period all the weaving of the country will share the fate of the spinning, and quit the cottage for those larger establishments in which it will be susceptible of better management, and more accurate division of labour.

The last improvement, which we shall notice in the manufacture of cotton, and which, when once established, will complete what Arkwright has so happily begun, is that of weaving by machinery. Various attempts have been made of late years to apply the great moving powers, steam and water, to the common loom. See *LOOM*.

**COUCH**, or **COAT**, in Painting, a term for each lay of colour, either in oil or water, with which the artist covers his canvass, wall, wainscot, or other matter, to be painted.

**COUCHING**, in Surgery, the operation of removing a cataract, which is done by a peculiar needle, called the couching needle.

**COULTER**, in Husbandry, an iron instrument fixed in the beam of a plough, and serving to cut the edge of each furrow.

**COUNCIL**. In this country, the law, in order to assist the king in the discharge of his duties, the maintenance of his dignity, and the exertion of his prerogative, hath assigned him a diversity of counsellors with whom he may advise.

1. The first of these is the high court of parliament.
2. The peers of the realm are, by their birth, hereditary counsellors of the crown.

3. A third council belonging to the king, are, according to Sir Edward Coke, his judges of the courts of law, for law matters. And this appears frequently in the English statutes, particularly 14 Edward III. c. 5, and in other books of law. So that when the king's council is mentioned generally, it must be defined, particularized, and understood, according to the subject matter; and if the subject be of a legal nature, then by the king's council is understood his council for matters of law; namely, his judges.

4. But the principal council belonging to the king is his privy council, which is generally, by way of eminence, called The Council, composed of eminent persons, the number of whom is at the sovereign's pleasure, who are bound, by oath, to advise the king, to the best of their judgment, with all the fidelity and secrecy that becomes their station. The king may declare to, or conceal from, his privy council whatever he thinks fit, and has a select council out of their number, commonly called the cabinet council, with whom his majesty determines such matters as are most important, and require the utmost secrecy. All proclamations from the king and the privy council ought to be grounded on law, otherwise they are not binding to the subject. Privy counsellors, though but gentlemen, have precedence of all the knights and younger sons of barons and viscounts, and are styled right honourable.

**COUNCIL**, *Common*, in the city of London, a court in which are made all by-laws which bind the citizens. It consists, like the parliament, of two houses, an upper, composed of the lord mayor and aldermen; and a lower, composed of a number of common councilmen chosen by the several wards, as representatives of the body of the citizens.

**COUNSELLOR AT LAW**, a person retained by a client to plead his cause in a court of judicature. There are two degrees of counsel, viz. barristers and serjeants. Barristers are called to the bar after a certain period of standing in the inns of court. After 16 years' standing, they may be called to the degree of serjeant. The judges of the courts of Westminster Hall are always admitted serjeants before they are advanced to the bench. From both serjeants and barristers the king's counsel are usually selected, the two principal of whom are the attorney and solicitor-general. Counsel are supposed to plead gratis, and can maintain no action for their fees; and to encourage in them a freedom of speech in the lawful defence of their clients, a counsellor is not answerable for any matter by him spoken, though it should prove groundless, and reflect on the reputation of another, provided it relates to the cause which he espouses, and is suggested in his client's instructions. And notwithstanding counsellors have a special privilege to practise the law, yet they are punishable for misbehaviour by attachment. No counsel is allowed to a prisoner upon a general issue of indictment of felony, unless some point of law arise; for the court is the prisoner's only counsel.

**COUNT**, originally, a nobleman who possessed a domain erected into a county. The dignity is a medium between that of a duke and a baron. It is now merely a title of honour.

**COUNT**, in Law, is the original declaration of complaint in a real action, as a declaration is in a personal one.

**COUNTER APPROACHES**, in Fortification, lines and trenches made by the besieged to attack the works of the besiegers, or to hinder their progress. The line of counter approach is a trench made by the besieged from their covered way to the right and left of the attacks, in order to scour the enemy's works.

**COUNTER BATTERY**, is one raised to play upon another to dismount its guns.

**COUNTER-GUARD**, in Fortification, a work raised before the point of a bastion.

**COUNTERMARCH**, a change of the face or wings of a battalion, whereby those that were in the front come in the rear. Also the returning or marching back again.

**COUNTERMINE**, in War, a well and gallery driven and sunk till it meets the enemy's mine, to prevent its effects.

**COUNTERPART**, in Music, denotes that one part is to be applied to another. Thus the bass is said to be the counterpart to the treble. In Law, it is the duplicate or copy of an indenture or deed.

**COUNTERPOINT**, in Music, the combining and modulating consonant sounds.

**COUNTERPOISE**, any weight which, placed in opposition to another weight, produces an equilibrium, but it is more commonly used to denote the weight used in the Roman balance or steelyard.

**COUNTERSCARP**, in Fortification, the exterior slope of the ditch, though it is often taken for the covered way and glacis. *Angle of the Counterscarp*, is that made by its two sides meeting before the middle of the curtain.

**COUNTERTENOR**, in Music, high tenor; a term applied to the highest natural male voice.

**COUNT-WHEEL**, in the striking part of a clock, is that which moves round once in 12 or 24 hours.

**COUP-DE-MAIN**, in Military affairs, implies a desperate resolution in small expeditions of surprise; or the attacking a place sword in hand.

**COUPURE**, in Fortification, passages sometimes cut through the glacis, of about twelve or fifteen feet broad, in the re-entering angle of the covert way, to facilitate the sallies of the besieged.

**COURSE**, in Navigation, the point of the compass, or horizon, which the ship steers on, or the angle which the rhumb line on which it sails makes with the meridian; and is sometimes reckoned in degrees, and sometimes in points and quarter points of the compass.

**COURSING**, among sportsmen, is of three sorts, viz. at the deer, at the hare, and at the fox. These coursings are with greyhounds; for the deer there are two sorts of coursings, the one with the paddock, the other either in the forest or purlieu.

**COURT**, a place for the administration of justice. The most general division of our courts is into those of record, and those which are not; those of record are divided into supreme and superior or inferior. The supreme court of this kingdom is the high court of parliament, which has an absolute power to make new laws, and to repeal and alter old ones. Superior courts of record are the House of Lords, the Chancery, King's Bench, Common Pleas, and Exchequer; the less principal are those held by commission of gaol delivery, oyer and terminer, assize, nisi prius, &c. The inferior courts of record are corporation courts, courts leet, the sheriff's torn, &c. Courts not of record are the courts baron, county courts, hundred courts, &c.; also the admiralty and ecclesiastical courts, which derive their authority from the crown, and are subject to the control of the king's temporal courts, if they exceed their jurisdiction.

**COURT BARON**, a court held by every lord of a manor within the same; and if the number of suitors should so fail as not to leave enough to make a jury or homage, that is, two tenants at least, the manor is lost. This court may inquire of the death of tenants, of nuisances, waste, trespass, forfeitures, &c. and the punishment is by amercement.

**COURT OF CONSCIENCE**, in the cities of London, Westminster, and some other places, determines matters in all cases, where the debt or damage is under forty shillings. In some places these courts have power to decide on larger sums.

**COVENANT**, in Law, the agreement or consent of two or more, by deed in writing, sealed and delivered; whereby either, or one of the parties, promises to the other, that something is done already, or shall be performed afterwards.

**COVERT-WAY**, or **CORRIDOR**, in Fortification, a space of ground, level with the field, on the edge of the ditch, three or four fathoms broad, ranging round the half-moons, and other works toward the country.

**COVERTURE**, in Law, a term applied to a married woman who is under the power of her husband, and therefore incapable of making bargains to the injury of herself or her husband.

**COVIN**, in Law, a deceitful assent or agreement between two or more, to the prejudice of another.

**CRAB**, a wooden pillar, somewhat resembling a small capstan, but not furnished with a drum head; instead of which,

two, three, or four holes are made one above another, through the middle of its upper end, into which long bars are thrust, whose length is nearly equal to the breadth of the deck. It is employed for the same purposes as the capstan, but not being so convenient, is now generally laid aside, except in ropewalks, &c. The Crab, a machine with three claws, is used to launch ships, and to heave them into the dock, or off the key. See **CANCER**, for the *Celestial Crab*.

**CRADLE**, a frame placed under the bottom of a ship, in order to conduct her steadily and smoothly into the water when she is to be launched, at which time it supports her weight while she slides down the descent or sloping passage, called the Ways, which are for this purpose daubed with soap or tallow. Cradles are also standing bedsteads made up for the wounded seamen, that they may be more comfortable than it is possible to be in a hammock.—Children's wicker cradles need hardly be alluded to; nor does the more fashionable rocking or swing cot require illustration, except to observe, that the principle of suspension is capable of great improvement upon a very simple plan, that of the pendulum, in place of the clumsy method of hanging the cot on a tawdry brass knob, by a piece of wire bent in the form of an equilateral triangle.

**CRAFT**, a general name for all sorts of vessels employed to load or discharge merchant ships, or to carry alongside, or return the guns, stores, or provisions of a man-of-war; such are lighters, hoys, barges, &c.

**CRAMBE**, *Sea Cabbage*, *Sea Beach Kale*, or *Sea Colewort*, a genus of the siliquosa order, in the tetradynamia class of plants, ranking in the natural method under the 39th order siliquosæ. There are six species, three herbaceous esculents with perennial roots, producing annually large leaves like those of the cabbage, spreading on the ground with yellow flowers. Only one species is a native of Britain, and it grows wild in several parts of the sea-coast. It is propagated by seeds sown in common light earth in autumn or spring. The *crambe fruticosa* is a greenhouse plant.

**CRAMP**, in Medicine, a convulsive contraction of a muscular part of the body, being either natural, as in convulsive constitutions, or accidental, from living in cold places, under ground, &c. It affects all parts indifferently, but the ham, calves, feet, and toes, oftener than the arms and hands. An effectual preventive for cramp in the calves of the legs, which is a most grievous pain, is to stretch out the heel of the leg as far as possible, at the same time drawing up the toes to the body. This will frequently stop the progress of a fit of the cramp after it has commenced; and a person will, after a few times, be able in general to prevent the fit coming on, though its approach be between sleep and waking.

**CRANE**, **THE**, a machine used in building, on wharfs, and in warehouses, for raising and lowering huge stones, ponderous weights, packages, bales of goods, &c. has been variously constructed, and will therefore require a few examples.

The *Cellar Crane* we have already noticed. The *Portable Stone Crane for Loading and Unloading Carts*, is mounted on a

wooden stage, and is so constructed that it may be taken to pieces. The frame A, A, A, A, is about 10 feet high and 9 feet

square; the wheels B, B, are of iron, and 3 feet diameter; the pinion D fixed to the axis of the first wheel B is 8 inches in diameter; and the other pinion C is about the same diameter. When stones are suspended to the rope that coils round the barrel, the labourer turns a winch on the axis of the wheel C, and raises or lowers the weight according to the direction in which he turns it.

*Gottlieb's Carriage Crane.*—This machine, which is useful for carrying large stones where carts and horses cannot be easily obtained, consists of two sorts of crane wheels applied to the

two sets of wheels belonging to the carriage, so that two men, one acting at each winch A, A, give motion to the loaded carriage. The pinion B, 6 inches in diameter, turns the wheel C, 3 feet in diameter. The wheel C gives motion to the pinion D, one foot in diameter, which works into two wheels E, E, 3 feet 6 inches diameter, and are fixed on the wheels of the carriage.

*Andrew's Weighing Crane,* weighs the body at the time that it raises it. The weight W is elevated by means of the levers M, H, O, N, which coils the rope T R round the barrel P. The jib E D stands on a horizontal beam, moveable in a vertical

plane round the centre F A, and the distance of the upright beam E from the centre of motion A, is  $\frac{1}{2}$  of B F. The weight of the bulk W is then ascertained by the weight at B, which keeps it in equilibrio. The piece of wood C projects from the vertical beam C L, in order to prevent the beam from rising too high.

*Ferguson's Crane* has three trundles, with different numbers of staves, that may be applied to the cogs of a horizontal wheel with an upright axle; round which is coiled the rope that draws up the weight. This wheel has 96 cogs; the largest trundle 24 staves, the next 12, and the smallest 6, so that the largest revolves 4 times for one revolution of the wheel; the next 8, and the smallest 16. A winch is occasionally fixed on the axis of either of these trundles, for turning it; and is applied to the one or the other according as the weight to be raised is smaller or larger. While this is drawing up, the ratch-teeth of a wheel slip round below a catch that falls into them, prevents the crane from turning backwards, and detains the weight in any part of its ascent, if the man who works at the winch should accidentally quit his hold, or wish to rest himself before the weight is completely raised. Making a due allowance for friction, a man may raise by such a crane from three times to twelve times as much in weight as would balance his effort at the winch; viz. from 90 to 360 lbs. taking the average labour.

*Bramah's Jib for Cranes.*—The nature of this invention may be easily understood from a bare inspection of the figure, which represents a jib attached to the wall of a warehouse. The jib turns on a perforated axis or pillar. The rope by which the weight is raised, after passing over two pulleys, goes through the perforated axis, and is conducted over another

all parts of the country.

*Watt's Jib Crane.*—Fig 1 is a side view of the crane, shewing the jib; fig. 2 is a back view, shewing the chain, barrels, and edges of the wheels and pinions; fig. 3 is a fulcrum, used in shifting the crane from place to place. The same reference-letters are put to the same points in both figures.

A B is the upright shaft. It is made of a firbalk 12 $\frac{1}{2}$  inches square, and 23 feet long. Its lower pivot turns in a cross step at A, and its upper one in a cross at B, supported by four gy-

ropes, two of which gg are shewn in each figure. Immediately above the pivot are two strong plates of cast iron, bolted to the opposite sides, for receiving the bolt at D, upon which the jib turns. Above these, the shaft is fortified by side pieces, till it has a breadth of 26 $\frac{1}{2}$  inches, where are fastened the cast-iron cheeks ss, of which an edge view is given in fig. 2, and which may be traced behind the wheels ii and nn, in fig. 1. Four brass beds, covered by capsquares of the same metal,

are placed in these checks, for receiving the axles of the wheels and pinions. Two strong cast-iron blocks, with grooved pulleys for the chains, are placed at c and r, upon opposite sides of the shaft.

C D is the jib, formed of two oak battens, 7 $\frac{1}{2}$  inches by 2 $\frac{1}{2}$  at their lower extremities, and 5 $\frac{1}{2}$  by 2 $\frac{1}{2}$  at their upper. They are 3 inches asunder at the lower extremity; where, and at the serpentine plate at the middle, they are separated by blocks, and they meet within a few feet of the upper extremity. The extremity D is fortified by two strong plates of cast-iron, which go within the plates in the shaft, and receive the axle-bolt; and the other two plates at the extremity C, contain a grooved pulley, shewn by the dotted circle at e, and a bolt for fastening the chain C r. The length of the jib from the axle-bolt at D to the centre of the pulley e, is 20 $\frac{1}{2}$  feet.

There are two chain-barrels. The barrel a raises or lowers the weight f, by means of the chain which passes over the pulleys c, d, e; and the barrel v contracts or expands the jib, by means of the chain which passes over the pulley r. The crane-barrel a is about 9 $\frac{1}{2}$  inches in diameter, and the jib-barrel v about 8 inches; and the chains for both are made with circular links from five-eighths inch iron rod. These barrels may be either both worked at the same time, in the same or in opposite directions, or either of them may be worked separately. The jib-barrel has a single power, produced by the pinion p, of 10 leaves, and 5 $\frac{1}{2}$  inches diameter, acting on the wheel nn, of 76 teeth, and 36 $\frac{1}{2}$  inches diameter. The pinion p

is moved by the winches *q q*, which have a lever power of 16 inches. The jib-barrel may be locked by pushing a moveable bolt, till it bear against an arm of the wheel *n n*. The single power of the crane-barrel is obtained by placing winches (16 inch) on the squares *k k* (fig. 2), which terminate an arbor passing through the centre of the jib-barrel, and having on its one end the wheel *i i*, and on its other the pinion *h* (fig. 2). The pinion *h* ( $5\frac{1}{2}$  inches diameter, 9 leaves,) moves the wheel *b b*, which is fastened on the arbor of the crane-barrel, and has  $36\frac{1}{2}$  inches diameter, and 76 teeth.

The double power is obtained by turning the pinion *l* by means of the winch *m* (16 inches), and one on the opposite end of the same arbor. The pinion *l* is  $8\frac{1}{2}$  inches diameter, and has 16 leaves, and the wheel *i i*, which it turns, is 32 inches diameter, and has 66 teeth. The check-block *d* is a single pulley kept in its place by the chains *t, u*, and is necessary for securing the action of the jib at all angles of elevation, by preserving the angle *D e d*, always smaller than the angle *D e f*, it being obvious, from the doctrine of the resolution of forces, that when these angles are exactly equal, the point of the jib will be in equilibrio; but that when they are unequal, it will have a tendency to move in the direction of the greater angle. When *D e f* is the greater, the jib can be prevented from falling down by the jib-chain *C r*; but if *D e d* were the greater, there is nothing to prevent it from rising till it would come in contact with A B.

The fulcrum (fig. 3) is, when the crane is to be shifted, placed near the axle-bolt of the jib at D; then the jib is lowered, and acts as a lever in taking the weight of the crane off the cross-foot. The cross-head of the fulcrum moves on a pivot in the tripod, and by means of it, and easing off two of the gy-ropes while the opposite ones are hauled in, the crane is moved along in an upright position.—The total cost of such a crane is about £70; and the parts are so constructed that it may be used for many years without requiring the smallest expense for repairs.

The power of the jib-barrel, without making allowance for friction, is about  $26\frac{1}{2}$ , when the winch is in an horizontal position; but as the resistance of the weight varies with every change in the elevation of the jib, it is not possible to calculate the power which would be necessary to move it with any given weight. The more that the jib is elevated, the less power is required. The single power of the crane-barrel, without making allowance for friction, is about  $24\frac{1}{2}$ , and the double power about 101. It is not possible to determine the friction exactly, because it varies both with the weight and the position of the chains, being more as the weight is greater, and the angles formed by the chains less. But the result of experiments made with a load of one ton, and the jib at an angle of about 45 degrees, were as follows:—

| <i>Single Power.</i>                                   |  | lbs. |
|--------------------------------------------------------|--|------|
| Power required to suspend a ton, by calculation, about |  | 91   |
| Ditto, by trial, with check block, about               |  | 154  |
| Total friction,                                        |  | 63   |
| Ditto, without check-block,                            |  | 128  |
| Friction on check-block,                               |  | 26   |
| <i>Double Power.</i>                                   |  |      |
| Power required to suspend a ton, by calculation, about |  | 22   |
| Ditto, by trial, with check-block, about               |  | 44   |
| Total friction,                                        |  | 22   |
| Ditto, without check-block,                            |  | 38   |
| Friction on check-block,                               |  | 6    |

Hence the whole friction on the single power is equal to about two-fifths, and that on the double power about one-half of the power employed; and the friction upon the check-block nearly one-seventh of the power in both cases. The small arc, however, over which the winch can traverse, without a great alteration of power, when trial is made by weight, suspended

from the winch, and the great strain produced by a pressure of two tons on the machine, render such experiments but very loose approximations.\*

As a building crane, this possesses many advantages over those commonly in use, from the complete command it has over every inch of space within the range of the jib. The common building crane, with a fixed jib and moveable truck, commands indeed the same angular range; but then the truck cannot, without an additional power, be removed farther from the shaft, after the crane is loaded, and thus its operation is confined. The common crane is also much less portable, and cannot be moved even for the shortest distance without being taken down—an operation which costs a good deal of time and labour. Indeed, in as far as portability, power, and the complete command of a given space are concerned, this crane is decidedly superior to every other; and in every case of building with large stones, where gy-ropes can be used, it deserves the preference. Where gy-ropes cannot be used, Mr. Watt's balance, or counterpoise crane, is equally applicable and excellent. Indeed, the whole machines invented by this ingenious mechanic, while employed at the construction of the Bell-Rock Lighthouse, form a series of applications of the mechanical powers highly unique and valuable; and shew of how much consequence it would be to the arts and to society, were mechanical genius in common workmen duly appreciated and regarded.—*Mech. Mag.* vol. ii. No. 54.

CRANE is also a popular name for a syphon employed in drawing off liquors. This crane or syphon is nothing else

than a bent tube, as A B G. If the shorter end A B be immersed in a vessel of water or other fluid, C, then by applying the mouth to the end G, and sucking till the liquor arrives there, it will continue to flow out at the end G, as long as that end is lower than the surface of the fluid in the vessel C. If there be a mouth-piece at E, then sucking at that mouth-piece (while the end G is stopt with a finger or otherwise,) will make the fluid flow when the obstruction is taken away from G. When the fluid has begun to flow, the hole at E must be stopped up, or the fluid will flow no longer than till the surface in the vessel be as low as E. The reason of the motion of the liquor in the syphon is this:—The perpendicular height of the column B G being greater than B A, the pressure of the atmosphere being the same at both orifices, supposing them of equal area, therefore the weight at G will cause the fluid to flow out there, while the pressure of the atmosphere will force more liquor up at the end A, and thus the motion will continue so long as there is any fluid in the vessel, provided the end G is lower than the end A of the syphon. Hence it is evident, that the height from the surface of the fluid to the top B must not exceed the altitude of a column of the fluid whose weight is equal to the pressure of the atmosphere on the same base, or the fluid may be drawn up by sucking at the aperture E, which must be closed as soon as the liquor is made to run. Many improvements have been made on this instrument, which it is not our purpose to repeat here.

CRANIOLOGY, is a science by which it is attempted, from the external shape of the skull, to form an opinion of the animal propensities and intellectual powers. A few words will serve to shew the principle on which it is founded. That the intellectual powers and animal propensities have their seat in the brain, has generally been admitted, but according to the doctrines of craniology, of which Drs. Gall and Spurzheim have

\* Still it is evident, that could the check-block be dispensed with, the power of the crane would be very much increased. Now, if the point of the jib did not require to be very much raised, the block might be dispensed with, by giving the pulley *c* a situation lower down to the shaft, such as *x*; but if it were brought very low, the chain would not coil properly on the barrel. This might, however, be obviated, by placing the crane-barrel on the other side of the shaft, and bringing the chain down the back of the jib from the pulley *e*, without passing it over any other pulley whatever. As, however, the placing of the barrel in this situation would prevent the jib from being brought so near to the shaft as it can be with the check-block; and as, notwithstanding the friction on the block, the crane is sufficiently powerful, the alteration is a matter of less importance.

been the chief propagators, these do not depend on the brain generally, but each distinct faculty and propensity has its seat in a particular portion of the brain. If therefore any part of the brain be unusually large in any individual, that individual will be distinguished for an extraordinary degree of the intellectual faculty, or animal propensity, of which the enlarged portion of the brain is the seat. If, on the other hand, any portion of the brain be unusually small, he will be remarkable for a deficiency of the particular faculty or propensity of which the diminished portion is the seat. As the enlargement of any portion of the brain will produce an elevation of the skull, particularly in infancy, when the bones are soft, the craniologists endeavour, by observing the protuberances of the skull, to form a judgment of any individual's intellectual powers or animal propensities. Drs. Gall and Spurzheim have attempted to fix, from observation of a number of remarkable individuals, what portions of the brain are the seat of the different faculties and propensities, and have accordingly divided the surface of the cranium into portions like the counties in a map of England. But the whole of this appears to the editor and author of this Dictionary absolute nonsense.

Such a system as this ought to have for its support observations on a very great number of individuals, and the cases which bear against it, as well as for it, ought to be candidly stated. The small number of cases, under each head in Dr. Spurzheim's work, is very remarkable, and the blunders made by professed craniologists, who have attempted to give the character of individuals whose skulls they have examined, and who were unknown to them, have much tended to destroy all faith in the accuracy of its conclusions. It also deserves to be noticed, that there are external elevations of the skull, where there are no corresponding internal elevations of the brain. The ridicule to which the subject has been exposed, has produced a great zeal in its professors, and whilst that continues, we may expect them to trumpet forth cases in their favour, and to say little of such as do not tend to bring credit to their favourite science.

**CRANK**, in Mechanics, a square piece projecting from a spindle, serving by its rotation to raise and fall the pistons of engines. It also denotes the iron support for a lantern, and the iron made fast to the stock of a bell.

**CRAPE**, a light stuff resembling gauze, made of raw silk gummed and twisted on the mill, and woven without crossing.

**CRATÆGUS**, *Wild Service Tree*, *Hawthorn*, &c. a genus of the digynia order, in the icosandria class of plants, ranking in the natural method under the 36th order, pomaceæ. There are 28 species, among which the wild service, or maple-leaved service, a large tree that grows in England, Germany, Switzerland, and France, is valuable for its timber.

**CRATER**, *the Cup*, is an ancient constellation, sufficiently typical by its place between the meridian intersecting the Lion and Virgin, of its use at the summer solstice, when Taurus opened the year. The fable which attributes this goblet to Bacchus, is a finely allegorized symbol of Noah's planting the vine; and the translation of the cup to a place in the heavens corresponding with the primitive solstice of astronomy, gives some support to the hypothesis that assigns to Bacchus an Asiatic origin.—The boundaries and contents of this constellation are: north by Virgo, east by Corvus, south and west by Hydra. There are 13 stars in this asterism, of which  $\theta$ ,  $\epsilon$ ,  $\delta$ ,  $\gamma$ ,  $\zeta$ , and  $\eta$ , form the demi-circumference of the lip.  $\alpha$  *Alkes* to the south, and  $\beta$ , determine the bottom of the vessel.

**CRAX**, *the Curassow*, a genus of birds belonging to the order of galinæ, of which there are five species, natives of India, Africa, and South America.

**CRAYON**, a general name for a coloured stone, earth, or other substance, used in designing or painting in pastel, whether reduced to a paste, or used in their primitive consistence. In this last manner red crayons are made of blood stone or red chalk, black ones of charcoal and black lead, &c. Crayons of all other colours are compositions of earth.

**CRAYON PAINTING**, requires, in many respects, a treatment different from that in oil, because all colours used dry are of a warmer complexion than when wet with oils, for which reason, to produce a rich picture, a greater portion of what are termed *cooling tints*, must be applied in crayon painting, than

would be proper in oil. The paper for crayon painting should be strong blue or gray, and free from knots. The artist should work sitting with the crayons in his lap, and the part of the picture he is painting should be rather below his face. The windows should be darkened to the height of six feet from the floor, and the subject to be painted so placed that the light may fall with advantage on the face.

**CREPITATION**, or **DETONATION**, in Chemistry, the noise made by some salts over the fire in calcination. In Surgery, the sound made by the ends of bones when the limb is moved, that the existence of a fracture may be ascertained.

**CREPUSCULUM**, in Astronomy, twilight; the time from the first dawn or appearance of the morning to the rising sun; and again, between the setting of the sun and the last remains of day. Pappus derives the word from *creperus*; which, he says, anciently signified uncertain, doubtful, viz. a dubious light. The crepusculum is usually computed to begin and end when the sun is about 18 degrees below the horizon; for then the stars of the sixth magnitude disappear in the morning, and appear in the evening. It is of longer duration in the solstices than in the equinoxes, and longer in an oblique than in a right sphere. The crepuscula are occasioned by the sun's rays refracted in our atmosphere, and reflected from the particles thereof to the eye. See **TWILIGHT**.

**CRESCENT**, in Heraldry, a bearing in the form of a new moon.

**CRESCENTIA**, *the Calabash Tree*, a genus of the angiospermia order, in the didynamia class of plants, ranking in the natural method under the 25th order, putamineæ. There are two species; 1. The *cujete*, with long narrow leaves, and a large oval fruit, is a native of the West India islands. Its height is 20 or 30 feet, and the flowers, which are of a yellowish green colour, striped and spotted with brown, are succeeded by large fruit of a spherical or oval form. 2. The *cucurbitana* or broad-leaved calabash, rises to the height of 15 or 20 feet; the flowers are smaller than those of the preceding, and of a deeper yellow. The fruit is round or oval. The shells of both are made use of for drinking cups, punch-bowls, and other purposes, some of them will hold fifteen pints of water. The wood of the tree is made into stools and other furniture.

**CREST**, in Armoury, the top part of the helmet, generally ornamental. In Heraldry, it is that part of the casque or helmet next the mantle.

**CRITHMUM**, *Samphire*, a genus of the digynia order, in the pentandria class of plants, ranking in the natural method under the 45th order, umbellatæ. There are three species, the principal of which is the maritimum or common marine samphire, which has a fibrous penetrating root; thick succulent branching stalks, rising two feet high; fleshy leaves, with round yellow flowers. It grows on the sea-coast among gravel and rocks. The principal use of it is as a pickle.

**CROCUS**, *Saffron*, a genus of the monogynia order, in the triandria class of plants, ranking in the natural method under the 6th order, ensatæ. There are two species, and of each several varieties.

**CRUISADE**, **CRUSADE**, or **CRUZADO**, a name given to the expeditions of the Christians against the Infidels, for the conquest of Palestine; so called, because those who engaged in the undertaking wore a cross on their clothes, and bore one on their standard. This expedition was also called the holy war, to which people flocked in great numbers out of pure devotion, the pope's bulls and the preaching of the priests of those days making it a point of conscience. The several nations engaged in the holy war, were distinguished by the different colours of their crosses: the English wore white, the French red, the Flemish green, the Germans black, and the Italians yellow. From this enterprise several orders of knighthood took their rise. They reckon eight croisades for the conquest of the Holy Land; the first begun in the year 1095, at the solicitation of the Greek emperor and the patriarch of Jerusalem.

**CROMLECH**, in British antiquities, huge broad flat stones, raised upon other stones set up on end. They are common in Anglesea, and are supposed by some persons to have been tombs, though others imagine that they were altars for religious services.

**CROSS**, an instrument used in surveying, for the purpose of

raising perpendiculars. It consists merely of two pair of sights set at right angles to each other, mounted on a staff, of a convenient height for use. The method of using it is, to get in a line with one pair of sights, the marks at the extremities of the base line, or that on which the perpendicular is to be raised, and through the other pair the mark or object to which the perpendicular is to be measured; and the line or distance between the foot of the staff and the object will be the perpendicular required. See SURVEYING.

**Cross-Multiplication.** See DUODECIMALS.

**Cross-Staff, or Fore-Staff,** an instrument formerly used by mariners, for taking the meridian altitude of the sun or stars.

**CROTALUS, Rattle-Snake,** a genus belonging to the order of amphibia serpentes. The banded rattle-snake is from three to five feet long, of a yellowish brown colour, marked throughout with transverse streaks or spots of deep brown, and from the head down the neck run two or three stripes of the same colour; the head is large, flat, and scaly; the rest of the upper part covered with large oval scales; the under parts are of a dingy colour, marked with numerous freckles; at the end of the tail is the rattle, consisting of several horny processes, which the animal elevates and shakes when irritated or disturbed. The rattle-snake lives upon frogs, squirrels, and birds. The two last it catches in an extraordinary manner, placing itself under the tree where they rest, and by shaking the rattle awakens them; they then flutter and jump about from spray to spray, till, tired and frightened, they fall into the mouth of the enemy beneath. Rattle-snakes abound in North and South America. Their bite is fatal, but they never attack a person without provocation. The striped rattle-snake, of a deep brown colour above, with pale yellow streaks forming large lozenges down the back, is also a native of America, and equally venomous. The wood rattle-snake is of a lighter colour than the two preceding. And the military rattle-snake, of a gray-brown, shaded on the back with red and marked with black spots, is smaller than the other kinds.

**CROTCHET**, in Music, a note or character of time marked thus, ♪, equal to half a minim and double a quaver.

**CROTCHETS**, marks enclosing a word or sentence to be distinguished from the rest, thus, [ ] or ( ).

**CROTON, Wild Ricinus**, which grows naturally in the south of France, and from it is made the turnsole used for colouring wines and jellies. This is made of the juice lodged between the empalement and the seeds; and if rubbed on cloths at first appears green, but soon changes to a purple. If these cloths are put into water, they will dye it of a claret colour. The rags thus dyed are brought to this country, and sold under the name of turnsole.

**CROW**, in Mechanics, a kind of iron lever, sharp at one end and a claw at the other, used for heaving or pushing great weights.

**CROWN**, in Astronomy. See CORONA.

**CROWN**, in Geometry, a plane ring, included between two concentric perimeters, generated by the motion of part of a right line round the centre, to which the moving part is not contiguous. The area of a crown is had by multiplying its breadth by the length of the middle periphery; for a series of

terms in arithmetical progression being  $n \times \frac{a+w}{2}$ , i. e. the sum

of the first and last multiplied by half the number of terms, the middle terms must be  $\frac{a+w}{2}$ , therefore, that multiplied by the breadth or sum of all the two terms will give the crown.

**CROWN**, is also a silver coinage of England, and many other countries; the English crown is equal in value to 5 shillings; the Danish crown is 2s. 8½d.; German, 4s. 7½d.; French, 4s. 9½d. sterling.

**CROWN-WHEEL OF A WATCH**, the upper wheel, which, by its motion, drives the balance. In royal pendulums it is called the swing wheel.

**CROWN-WORK**, in Fortification, an outwork having a large gorge, and two long sides terminating towards the field in two demi-bastions. It is intended to enclose a rising ground, or to cover an entrenchment.

**CROW'S BILL**, a surgical instrument for extracting balls and other substances from wounds.

**CROW'S FEET**, in Military affairs, machines of iron having four points so made that whatever way they fall there is a point upwards; these are thrown upon breaches, or in passes, to lame the horses of the enemy.

**CRUCIBLE**, a chemical vessel made of earth, and so tempered as to endure the strongest heat.

**CRUSTACEOUS FISH**, are those covered with shells, consisting of several pieces or scales, as crabs, lobsters, &c.

**CRUX, the Cross**, is an asterism containing five stars, viz. one of the 1st magnitude, two of the 2d, one of the 3d, and one of the 4th. Four of these stars are in the form of a cross, and the most northerly and southerly are always in a line with the south pole. They are, therefore, the *Pointers* for discerning, in the southern hemisphere, the Antarctic pole. α, of the 1st magnitude, in the foot of the Cross, has 12 ho. 16' 48" right ascension in Time (Ann. Var. 3<sup>rd</sup>.23), and 62° 6' 49" south declination, (Ann. Var. + 20<sup>th</sup>.00.) γ, of the 2d magnitude, in the top of the Cross, has 12 ho. 21' 20", (Ann. Var. 3<sup>rd</sup>.24), and 56° 6' 41" south declination, (Ann. Var. + 19<sup>th</sup>.97.) β, of the 2d magnitude, in the arm, has 12 ho. 37' 24", (Ann. Var. 3<sup>rd</sup>.41,) and 58° 42' 53" south declination, (Ann. Var. + 19<sup>th</sup>.80.)

**CRYSTAL**, in Natural History, the name of a large class of fossils, hard, pellucid, and colourless.

**CRYSTALLINE HEAVENS**, in the old Astronomy, two orbs imagined between the primum mobile and the firmament, in the Ptolemaic system, in which the heavens are supposed solid, and only susceptible of a single motion. These orbs are said to have been introduced by Alphonsus, in order to explain what the ancients called the motion of trepidation or titubation.

**CRYSTALLIZATION**. When fluid substances become solid they frequently assume regular polyhedral forms, which are called *crystals*, and the bodies which do so are said to be susceptible of crystallization. Many minerals are found which are thus arranged into regular forms.

To enable the particles of bodies to assume that regular form which crystals exhibit, they must have freedom of motion; and, accordingly, the first step is to confer a liquid or aëriform state, by solution in water. When common salt is dissolved in water, the particles will be too far asunder to exert reciprocal attraction; in other words, they will be more powerfully attracted by the water than by each other. If we now get rid of a portion of the water by evaporation, the saline particles will gradually approach each other, and will aggregate according to certain laws, producing a regular solid of a cubic form. If the process be slowly conducted, the particles unite with great regularity; if hurried, the crystals are irregular and confused.

There are certain bodies which may be liquefied by heat, and during slow cooling may be made to crystallize. This is the case with many of the metals, and with sulphur. Some other substances, when heated, readily assume the state of vapour, and during condensation present regular crystalline forms, such as iodine, benzoic acid, camphor, &c.

The hardness, brilliancy, and transparency of crystals often depend upon their containing water, which sometimes exists in them in large quantities.

Thus sulphate of soda, in the state of crystals, contains more than half its weight. This is called water of crystallization. Some salts part with it by a simple exposure to dry air, when they are said to effloresce; but there are other salts which deliquesce, or attract water from the atmosphere.

Crystallization is accelerated by introducing into the solution a nucleus, or solid body, upon which the process begins, and manufacturers often avail themselves of this circumstance.

A strong saline solution excluded from the air will frequently crystallize the instant that air is admitted, a circumstance referred to atmospheric pressure. In other cases agitation produces the same effect. The presence of light also influences the process of crystallization. Thus the crystals collected in camphor bottles in druggists' windows, are always most copious upon the surface exposed to the light. Crystallized bodies affect one form in preference to others. The fluor spar of Derbyshire crystallizes in cubes; so does common salt; nitre in the form of a six-sided prism; and sulphate of magnesia

in that of a four-sided prism. These forms are liable to vary. Fluor spar and salt crystallize sometimes in the form of octahedra; and there are so many forms of carbonate of lime, that it is difficult to select that which most commonly occurs.

Rome de Lisle referred these variations of form to certain transactions of an invariable primitive nucleus. Bergman suspected the existence of a primitive nucleus in all primitive bodies. When Haiy entered this field of inquiry, he not only corroborated the opinions of Bergman, but traced with much success the laws of crystallization, and pointed out the mode of transition from primitive to secondary figures.

Dr. Wollaston supposed the primitive particles to be of a spherical form, and that their mutual attraction produces crystallization in the various regular forms in which it appears.—When alum is dissolved in water, various figures appear upon it. Those who are in the habit of cutting and polishing certain gems, have long known that they only afford smooth surfaces when broken in one direction.—*Watkin's Cyclopædia.*

**CRYSTALLOGRAPHY**, the science which attempts to explain the laws by which crystallization takes place.

**CRYSTALLIZING the Surface of Tin and other Metals.**—The process of giving the new ornamental surface on metals or metallic compositions, consists in employing those acids and saline compounds and substances which chemically act upon tin, and which, when employed in the manner to be stated, presently give to the metal or metallic compositions to which they are applied, the appearance of a crystalline surface variously modified; to produce this effect, the metal or metallic composition ought to be previously tinned or covered with a thin coat of tin. If the metal be pure tin, it requires no previous preparation. All grease remaining on the tinned surface, in consequence of tinning, is to be taken off with a solution of potash, soap, or any alkaline substances. The tin or tinned surface should then be washed with pure water, dried, and heated to a temperature which the hand can bear; when the surface has thus been cleaned and heated, any of the acids which act upon tin, or the vapours of these, will cause the desired appearance of crystallization, but preference is given to the following composition, which may conveniently be laid over with a brush or a sponge: take one part by measure of sulphuric acid, dilute it with five parts of water. Take also one part of nitric acid, and dilute it with an equal bulk of water, and keep each of the mixtures separate; then take ten parts of the sulphuric acid, dilute it in the manner before stated, and mix it with one part of the diluted nitric acid, and then apply this mixed acid to the tin, or to the tinned surface, with a pencil or sponge, as above directed, and repeat the application of the said composition for several times successively, or until the result you expect proves satisfactory: when this has been done, the crystalline surface may be covered with a varnish or japan, more or less transparent and colourless, or coloured; the whole must now be polished.

**CUBATURE**, is the finding the solid content of any proposed body, the same as quadrature signifies the finding the superficial area.

**CUBE, or HEXAHEDRON**, a solid regular body, consisting of six equal square sides. It is supposed to be generated by the motion of a square plane along a line equal and perpendicular to one of its sides.

*To determine the Surface and Solidity of a Cube.*—Multiply one side by itself, which will give one square; this multiplied by 6 will give the whole surface. Also, multiply one side twice by itself, that is, cube it, and that will give the solid content required.

**CUBE, Duplication of the,** is the finding of the side of a cube that shall double in solidity a given cube. It cannot be done geometrically, as it requires the solution of a cubic equation, or the finding two mean proportionals. Let  $a$  be the side of the given cube, and  $z$  that of the double one, then  $z^3 = 2a^3$ , or  $a^3 : z^3 :: z : 2a$ , therefore, if  $a$  and  $z$  be the first and second terms of a set of continued proportionals, then  $a^2 : z^2$  is the ratio of the square of the first to that of the second, which is the same as the ratio of the first term to the third, or the second to the fourth, or of  $z$  to  $2a$ ; therefore  $z$  being the second term,  $2a$  will be the fourth; so that  $z$ , the side of the cube sought, is the second of four terms in continued proportion; the first and

fourth being  $a$  and  $2a$ , i. e. the side of the double cube is the first of the two mean proportionals between  $a$  and  $2a$ .

**CUBEB, POWDER OF**, though not yet enrolled in the Pharmacopœia of London, is an article much used by our medical practitioners, to reduce inflammations of the pudenda, attended with the discharge of a mucus. This disease, sometimes mistaken for a venereal affection, is perfectly local, and may be easily cured by taking at night and morning a small portion of the powder of cubeb; thus, half an ounce of the powder made up into twelve parcels, will make doses for six days, during which time the parts affected may be well syringed with warm water and milk; or about 20 drops of port wine thrown into a glass of lukewarm water, makes perhaps a more efficacious wash. If the inflammation is not reduced in a week, the applications should be continued till the discharge entirely disappears.

**CUBEBS**, the *Cubeba* of Medicine, is a small dried fruit, resembling pepper, brought from Java.

**CUBES, or CUBE NUMBERS**, in Arithmetic, and the *Theory of Numbers*, are those whose cube root is a complete integer; or they are numbers produced by multiplying a given number twice into itself, or by the multiplication of three equal factors, thus,  $1 \times 1 \times 1 = 1$ ;  $2 \times 2 \times 2 = 8$ ;  $3 \times 3 \times 3 = 27$ ;  $4 \times 4 \times 4 = 64$ , &c. are cube numbers.

*To find the Cube Root of a given Number.*—1st Method. Separate the given number into periods of three figures each, by putting a point over the place of units, another over the place of thousands, and so on over every third figure, to the left hand in integers, and to the right in decimals; and then find the nearest cube root of the first period, and set it in the quotient. 2. Subtract the cube of the figure of the root thus found, from the first period, to the left hand, and annex the following period to the remainder for a dividend. 3. Divide this dividend by 3 times the square of the figure of the root above determined, and the first figure of the quotient will be the second figure of the root. 4. Subtract the cube of these two figures of the root from the first two periods on the left, and to the remainder annex the following period, for a new dividend, which divide as before; and so on till the whole is finished. And finally, point off as many figures for integers as there are periods of integers in the proposed number.

*Example.* Required the cube root of 41278·242816.

$$\begin{array}{rcl}
 & 41278 \cdot 242816 & (34 \cdot 56 \text{ root} \\
 3^3 = & 27 & \\
 \hline
 3^2 \times 3 = & 27 & ) 14278 \quad (4 \text{ 2d figure of the root} \\
 & & 41278 \quad \text{1st two periods} \\
 34^3 = & 39304 & \\
 \hline
 34^2 \times 3 = & 3468 & ) 1974 \cdot 242 \quad (5, \text{ 3d figure} \\
 & & 41278 \cdot 242 \quad \text{1st three periods} \\
 345^3 = & & 41063 \cdot 625 \\
 \hline
 345^2 \times 3 = & 357075 & ) 214 \cdot 617816 \quad (6 \cdot 4\text{-th figure}
 \end{array}$$

and thus the operation may be carried on till the root be obtained to any degree of accuracy required. This method, however, is extremely laborious, and is seldom or never employed, as other methods have been found in which the approximation is carried on much more rapidly.

**2d Method.** Find by trials the nearest rational cube to the given number, and call it the assumed cube. Then, as double the assumed cube added to the given number, is to double the given number added to the assumed cube, so is the root of the assumed cube to the required root, nearly. Or, as the first sum is to the difference of the given number and assumed cube, so is the assumed root to the difference of the roots, nearly.—By taking the cube of the root thus found, for the assumed cube, and repeating the operation, the root will be had to a still greater degree of exactness.

**3d Method.** Point off the given number in periods of three figures each, reckoning from the units' place: then find the cube of the first period on the right hand, set it down under that period, and subtract the one from the other, and to the remainder bring down the next period. To find the cube of this period, square the quotient, and multiply the product by

300 for a new divisor. Find how often this divisor is contained in the dividend, set it down, and bring down the two first periods in the dividend; cube the quotient figures, place their value under the original dividend periods, and subtract as before, and proceed thus till all the dividend is brought down.

*Example.* 14886936 is the number whose cube root is ought.

$$\begin{array}{r}
 2 \times 2 \times 2 = 8 \quad 14\text{ }886\text{ }936 \text{ ( } 246 \\
 \hline
 6\text{ }886 \\
 2 \times 2 \times 300 = 1200 \quad 16886 \\
 24 \times 24 \times 24 = 13824 \\
 \hline
 3062936 \\
 24 \times 24 \times 300 = 172800 \quad 14\text{ }886\text{ }936 \\
 246 \times 246 \times 246 = 14\text{ }886\text{ }936
 \end{array}$$

**CUBICAL EQUATION**, in Algebra, one whose highest power consists of three dimensions, as  $x^3 = a^3 - b^3$ , or  $x^3 + r x^2 = b^6$ , &c.

**CUBIT**, a measure of length equal to a man's arm from the elbow to the extremity of the fingers. Dr. Arbuthnot states the English cubit at 18 inches, the Roman at 1 foot 5.406 inches, and the Hebrew at 1 foot 9.888 inches.

**CUCULUS**, the *Cuckoo*, a genus of birds belonging to the order of picæ. The cuckoo appears in the spring, and takes its departure early in July. Some of these birds, however, have been found to winter in this island, taking up their abode in hollow trees, where they have lain in a torpid state. The cuckoo does not rear her own offspring, but selects the nest of some other bird, particularly that of the hedge-sparrow, in which she deposits her eggs. When the sparrow has sat her usual time, and disengaged the young cuckoo from her shell, her own young ones are soon turned out by the intruder, who remains in possession of the nest. There are many more male cuckoos than females, for when five or six have been taken in a trap, not a female has been found among them. Cuckoos may be brought up tame. They will eat bread and milk, fruit, insects, and flesh.

**CUCUMBER**, *Cucumis*, a genus of the syngenesia order, in the monœcia class of plants, ranking in the natural method under the 34th order, cucurbitaceæ. There are 13 species.

**CUCURBIT**, in Chemistry, an earthen or glass vessel, so called from its resemblance to a gourd.

**CUCURBITA**, the *Gourd and Pompion*, a genus of the syngenesia order, in the monœcia class of plants, ranking in the natural method under the 34th order cucurbitaceæ. There are seven species.

**CUIRASS**, a piece of defensive armour, made of iron plate, well hammered, serving to cover the body from the neck to the girdle, both before and behind.

**CULEX**, the *Gnat*, a genus of insects of the order of diptera, of which there are seven species. Before they attain the flying state, they are small grubs in the water, after which they turn to chrysalids, then pass to the state of a gnat, and fly into the air.

**CULMINATE**, to be vertical to, or on the meridian: hence the *culminating point*, is that point of a circle of the sphere that is on the meridian.

**CULMINATION**, in Astronomy, signifies the passage of any heavenly body over the meridian, or its greatest altitude during its diurnal revolution. In order to find the time of a star's culminating, we must estimate the time nearly, and find the right ascension both of the sun and star corrected for this estimated time; then the difference between these right ascensions, converted into solar time, at the rate of 15 degrees to the hour, gives the time of southing.

**CULVERIN**, a long slender piece of ordnance or artillery, for carrying a ball to a great distance.

**CUMINUM**, *Cummin*, a genus of the digynia order, in the pentandria class of plants, ranking in the natural method under the 45th order, umbellatæ. There is only one species which is an annual, that rises nine or ten inches high in warm countries. The flowers are of a pale blue colour; and the seeds

have an aromatic taste. These are used in the emplastrum cumini of the Pharmacopœia.

**CUNEUS**, the Latin term for wedge. See **WEDGE**.

**CUNITIA**, a celebrated lady of Silesia, authoress of a mathematical work entitled "*Urania Propitia*," published in 1650, in Latin and German; in which are contained various accurate astronomical tables calculated upon Kepler's hypothesis.

**CUPEL**, a shallow earthen vessel resembling a cup, from which it derives its name, is made of phosphate of lime, or the residue of burned bones rammed into a mould, which gives its figure. This vessel is used in assays wherein the precious metals are fused with lead, which becomes converted into glass, and carries the impure alloy with it.

**CUPELLATION**, the art of refining gold or silver by means of a cupel. For this purpose another vessel called a muffle is used, within which may be placed one or more cupels.

**CUP-GALLS**, formed on the leaves of the oak and other trees, resemble a drinking-glass with a cover, which last is flat, and has a small protuberance in the centre.

**CUOLA**, in Architecture, a spherical vault, or the round top of the dome of a church.

**CUPPING**, in Surgery, the operation of applying cupping-glasses, for the local discharge of blood and other humours by the skin.

**CUPRESSUS**, the *Cypress-tree*, a genus of the monadelphina order, in the monoœcia class of plants, ranking in the natural method under the 51st order, coniferae, of which there are seven species, all raised from seeds, and sometimes from cuttings. The wood of the evergreen cypress is said to resist worms, moths, and putrefaction, and to endure for ages. This tree has also been celebrated as a remedy in pulmonic diseases, from its supposed property of meliorating the air by its balsamic exhalations.

**CURATE**, the parson, or vicar of a parish, who has the charge or cure of the parishioners' souls; or, a person substituted by the incumbent, to serve his cure in his stead.

**CURATOR**, among Civilians, one appointed to manage the affairs of minors, or persons incapable of acting for themselves.

**CURCULIO**, the *weevil*, a genus of insects belonging to the order of coleoptera; and of which there are fifteen species, whose larvæ commit great ravages in corn-lofts, burying themselves in the grain, and entirely devouring the meal. When the insect arrives to its full size it becomes a chrysalis. Other larvæ fix themselves in beans, peas, and lentiles, artichokes, thistles, and the leaves of the elm tree.

**CURCUMA**, *Turmeric*, a genus of the monogynia order, in the monandria class of plants, ranking in the natural method under the 8th order, scitamineæ, and of which there are three species, that grow naturally in India, whence the roots are brought to Europe, to be used in dyeing yellow: and in medicine as a remedy for the jaundice.

**CURFEW**, a signal given in cities taken in war, &c. to the inhabitants to go to bed, and advertise the people to secure themselves from the robberies and debaucheries of the night. The most eminent curfew in England, was that established by William the Conqueror, who appointed, under severe penalties, that, at the ringing of a bell, at eight o'clock in the evening, every one should put out their lights and fires, and go to bed: whence to this day, a bell, rung about that time, is called a curfew-bell.

**CURING FISH AND BACON**.—The following simple and easy mode of preserving mackarel, pilchards, herrings, and sprats, has been proved by experience to answer well. Half fill some water-tight casks or vats, with a brine made from about 28 parts of solid salt to 72 parts of fresh water. Into this brine, the fish, gutted or not, are thrown as fresh as possible, sufficient to nearly fill the vessel. Some moisture will exude from the fish during the pickling, therefore add more salt to saturate it; and as the brine is always weakest in the upper part, a piece of basket work, or lattice work frame, should be provided, to fit inside of the cask or vat, and sunk an inch or two below the surface of the brine, upon which is to be placed some large lumps of solid salt, which will keep fully saturated the whole of the liquor, and keep it so as long as the lumps remain undissolved.

The solidity of these lumps admit of their being applied several times, or as often as the vessels are replenished with fish. The fish are to remain thus immersed in the liquor for five or six days, when they may be taken and packed in large grained salt, as usual. Various sorts of provisions are best preserved by this process, particularly bacon, which is not so liable to become rancid.

**CURRENTS**, the fruit of a species of grossularia. The white and red sorts are mostly esteemed; the black are employed to flavour English spirits, and counterfeit French brandies. The jelly is reckoned efficacious in sore throats. *Currents* also signify a small kind of grapes brought from Zante and Cephalonia.

**CURRENTS**, in Navigation, are certain settings of the stream, by which ships are obliged to alter their course, in order to arrive at the destined port. The *setting* of the current is that point of the compass to which the waters run; and the *drift* of the current is the rate it runs per hour. For the method of determining their course and drift, see Robertson's "Navigation," vol. ii. book 7, sect. 8, where the sailing in currents is largely exemplified.

**CURRYING**, the method of preparing leather with oil, tallow, &c. The skins when they come from the tanner are soaked in water; then stretched on a wooden horse, and being well scraped are put to soak again. While wet they are placed on a hurdle and trampled upon, to make them soft and pliant. In the next place they are soaked in train oil, and when taken out are fastened to large tables. Then the currier with an instrument called a pummel, which is a thick piece of wood, having the under side full of furrows crossing each other, folds, squeezes, and moves them backwards and forwards under the teeth of the instrument, to break their stiffness. This last is called currying: after which operation the skins are either coloured or made white. This last is done by rubbing them with chalk or white lead, and afterwards with pumice-stone. When a skin is to be made black, after it is oiled and dried, the currier passes over it a puff dipt in water impregnated with iron; he next gives it another wetting with a water prepared with soot, vinegar, and gum-arabic. This last operation is repeated till the skin is of a shining black.

**CURSITOR**, an officer belonging to the chancery, who makes out the original writs. There are twenty-four cursitors allotted to several counties.

**CURSOR**, a Runner, or Messenger, a small sliding piece of brass, in some mathematical instruments, as the piece of an equinoxial ring-dial, which slides to the day of the month, the point that slides along the beam compass, &c.

**CURTAIN**, or **CURTIN**, in Fortification, that part of the rampart of a place between the flanks of two bastions, bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covered way and into the moat.

**CURTATE Distance**, in Astronomy, is the distance of a planet's place from the sun or earth, reduced to the ecliptic; or, the interval between the sun or earth, and that point where a perpendicular, let fall from the planet, meets with the ecliptic.

**CURTATION**, is the interval between a planet's distance from the sun, and the curtate distance.

**CURVATURE** of a **LINE**, is its bending or flexure, by which it becomes a curve of any particular form and properties. Thus, the nature of the curvature of the circle is such, that every point in the periphery is equally distant from a point within called the centre; and so the curvature of the same circle is every where the same, but the curvature of all other curves is continually varying. The curvature of a circle is so much the more, as its radius is less, being always reciprocally as the radius and the curvature of other curves is measured by the reciprocal of the radius of a circle, having the same degree of curvature as any curve has, at some certain point. Every curve is bent from its tangent by its curvature, the measure of which is the same as that of the angle of contact formed by the curve and tangent. Now the same tangent is in common to an infinite number of circles, or other curves, all touching it and each other in the same point of contact. So that any curve may be touched by an infinite number of different circles at the same point; and some of these circles fall wholly within it, being more curved, or having a greater

curvature than that curve; while others fall without it near the point of contact, or between the curve and tangent at that point, and so being less deflected from the tangent than the curve is, they have a less degree of curvature there; consequently there is one, of this infinite number of circles, which neither falls below it nor above it, but, being equally deflected from the tangent, coincides with it most intimately of all the circles; and the radius of this circle is called the radius of curvature of the curve; also the circle itself is called the circle of curvature, or the osculatory circle, of that curve, because it touches it so closely that no other circle can be drawn between it and the curve.

**CURVE**, in Geometry, is a line, the several parts of which proceed in different directions, and are successively posited towards different points in space.

A **plane CURVE**, is that of which the several points in it lie in the same plane; and when this is not the case, the curve is said to be one of double curvature.

**CURVE Lines** are distinguished into algebraical or geometrical, and transcendental or mechanical. *Algebraical* or *Geometrical CURVES*, are those in which the relation of the abscisses to the ordinates can be expressed by a common algebraical expression. *Transcendental* or *Mechanical CURVES*, are such as cannot be defined or expressed by an algebraical equation; or when they are expressed by an equation, one of its terms is a variable quantity, or a curve line.

**Family of CURVES**, is an assemblage of several curves of different kinds, all defined by the same equation of an indeterminate degree; but differently, according to the diversity of their kind.

**CURVE of Double Curvature**, is used to denote the curve-line, all the parts of which are not situated in the same plane. A curve which can only be traced upon a curve surface, and not upon a plane surface, is called a curve of a double curvature. These kinds of curves may be considered as generated by the track of a point which is moved upon a curve surface, the direction of its motion being continually deflected either towards the right, or towards the left hand; thus it happens that the line so described is curved, in two senses; for in effect, is partakes of the curvature of the curve surfaces, and of the continual and successive deflections of the describing point. Two curve surfaces which mutually penetrate each other, form also, in general, by their intersection, a curve of double curvature. Such, for example, is the curve which is formed by the mutual penetration of a right cylinder and a sphere, supposing that the axis of the cylinder does not pass through the centre of the sphere. We have said in general, for it may happen on account of particular circumstances, that the intersections of two curve surfaces is a plane curve. Thus, in the preceding example, if the axis of the cylinder passed through the centre of the sphere, the curve of intersection would be the common circle. Ingenious disquisitions on curves of double curvature, have been given by Euler and La Croix.

**CURVILINEAR**, any thing relating to curves, as curvilinear angle, figure, surface, &c. being such as are formed or bounded by curves.

**CUSCUTA**, *Dodder*, a genus of the digynia order, in the tetrandria class of plants, ranking in the natural method under the dubious order. There are four species, one of which is a native of Britain, viz. The *Europæa*, dodder, hell-weed, or devil's guts; a singular plant, almost destitute of leaves, creeping and fastening on whatever is next to it. It decays at the root, and afterwards is nourished by the plant to which it adheres. Hops, flax, and nettles are its common supporters.

**CUSP**, **CUSPIS**, in Astronomy, properly denotes the point of a spear, but is used to express the points or horns of the moon, or other luminary.

**CUSP**, in Geometry, is used for the point, or corner, formed by two parts of a curve meeting and terminating there.

**CUSTOM**, a law, not written, which from long usage and consent becomes a matter of right. It is either general or particular; the first when allowed throughout England; particular when confined to a particular district.

**CUSTOM** is also a very comprehensive term, denoting the manners, ceremonies, and fashions of a people, which having

turned into a habit, and passed into use, obtains the force of laws; in which sense it implies such usages as, though voluntary at first, are yet, by practice, become necessary. Custom is hence defined, a law not written, but established by long usage, and the consent of our ancestors; in which sense it stands opposed to the written law. All customs ought to have a reasonable commencement, be certain, not ambiguous, have had uninterrupted continuance, and not be against the king's prerogative.

**CUSTOM of London:** it is a custom of London, that where a person is educated in one trade, he may set up another; that where a woman uses a trade without her husband, she is chargeable alone, as a *femme sole* merchant, and, if condemned, she be put in prison till she pays the debt; likewise the bail for her are liable if she absent herself, and the husband, in these cases, shall not be charged. If a debtor be a fugitive, by the custom of London he may be arrested before the day, in order to find better security, &c. These are customs of London, different from those of other places.

**CUSTOM of Merchants:** if a merchant gives a character of a stranger to one who sells him goods, he may be obliged to satisfy the debt of the stranger for the goods sold, by the custom of merchants. And when two persons are found in arrears, upon an account grounded on the custom of merchants, either of them may be charged to pay the whole sum due, &c. Various other cases depend on what is understood as the usual custom of commercial men.

**CUSTOMS,** in Commerce, the duties or taxes payable upon the importation or exportation of merchandise. They appear to have been originally levied to reimburse the sovereign for the expense he incurred in protecting foreign trade, and were considered as taxes upon the profits of the merchants, being imposed equally upon all sorts of goods, necessities as well as luxuries.

**CUSTOS BREVIUM,** the principal clerk in the Court of Common Pleas, who keeps all the writs made returnable in that court, and makes entries of writs of covenant, &c.

**CUSTOS MESSIUM.** Monsieur de la Lande introduced this asterism in honour of the celebrated astronomer Messier, and in allusion to his name it has been called the *Guardian of the Harvests*.—The boundaries and contents are: south by Cassiopeia, east by Cepheus, north by Tarandus, and west by Camelopardalis. Right ascension  $35^{\circ}$ , and  $68^{\circ}$  declination north. The stars, about ten in number, are mostly invisible to the naked eye.

**CUSTOS ROTULORUM,** an officer who has the care of the rolls and records of the sessions of peace, also of the commission of the peace.

**CUT-WATER,** in a ship, is the sharp part of the head under the beak or figure.

**CUTICULA,** in Anatomy, a thin membrane close upon the skin or cutis, of which it seems to be a part, and to which it firmly adheres by the corpus reticulare.

**CUTIS,** in Anatomy, the skin, that strong covering which envelopes the whole surface of animals, and which consists chiefly of two parts, a thin white elastic layer on the outside called the epidermis or cuticle; and a thick one composed of many fibres closely interwoven and disposed in different directions, called the cutis or true skin.

**CUTLERY,** in the general sense comprises all those articles denominated edge-tools, but it is more particularly confined to the manufacture of knives, forks, scissars, penknives, razors, swords, and surgical instruments.

**CUTTER,** a sloop-rigged vessel built sharp for sailing; generally used in smuggling, or in the navy to watch the coast, and to look after vessels engaged in contraband trade.

**CYCAS,** a genus of plants belonging to the first natural order palmæ. The fruit is a dry plum with a bivalve kernel. There are two species; 1. The *circinalis* or sago tree, which grows in the East Indies, particularly on the coast of Malabar. It rises to the height of forty feet, and the leaves are seven or eight feet long. The flowers grow in long bunches at the foot-stalks of the leaves, and are succeeded by oval fruit, about the size of large plums, of a red colour when ripe, and of a sweet taste. Each contains a nut enclosing a white kernel which tastes like the chestnut. The inhabitants of India saw the

body of the tree into pieces, then beat them into a mortar and pour water upon it. When strained, a fine mealy substance comes off, which is made into bread. The same meal finely powdered is made into sago. 2. The *cyas revoluta*, or bread tree of the Hottentots, discovered by Thunberg, has a pith which abounds in the trunk, and is collected and tied up in skins, and buried some weeks till it is tender enough to be kneaded, and then it is made into loaves of frumenty.

**CYCLE,** a certain period or series of numbers, proceeding orderly from first to last, then returning again to the first, and so circulating perpetually. Cycles have chiefly arisen from the incommensurability of the revolutions of the earth and celestial bodies to one another. The apparent revolution of the sun about the earth, has been arbitrarily divided into 24 hours, which is the basis or foundation of all our mensuration of time, whether days, years, &c. But neither the annual motion of the sun, nor that of the other heavenly bodies, can be measured exactly, and without any remainder, by hours, or their multiples. That of the sun, for example, is 365 days, 5 hours, 49 minutes, nearly; that of the moon, 29 days, 12 hours, 44 minutes, nearly. Hence, in order to express these fractions in whole numbers, and yet in numbers which only express days and years, cycles have been invented; which, comprehending several revolutions of the same body, replace it, after a certain number of years, in the same points of the heaven whence it first departed; or, which is the same thing, in the same place of the civil calendar.

The most remarkable of these are the following:—*The Cycle of the Sun, or Solar Cycle*, is a revolution of 28 years, in which time the days of the months return again to the same days of the week; the sun's place to the same signs and degrees of the ecliptic on the same month and days, so as not to differ one degree in 100 years; and the leap-years begin the same course over again, with respect to the days of the week on which the days of the month fall. *The Cycle of the Moon*, commonly called the *Golden Number*, is a revolution of 19 years; in which time the conjunctions, oppositions, and other aspects of the moon, are within an hour and a half of being the same as they were on the same days of the months 19 years before. The Indiction is a revolution of 15 years, used only by the Romans, for indicating the times of certain payments, made by the subjects to the republic. It was established by Constantine, A. D. 312.

The year of our Saviour's birth, according to the vulgar æra, was the ninth year of the solar cycle, the first year of the lunar cycle; and the 312th year after his birth, was the first year after the Roman Indiction. Hence, to find the year of the *Solar Cycle*, add 9 to any given year of Christ, and divide the sum by 28, the quotient is the number of cycles elapsed since his birth, and the remainder is the cycle for the given year: if nothing remains, the cycle is 28.

To find the *Lunar Cycle*.—Add one to the given year of Christ, and divide the sum by 19; the quotient is the number of cycles elapsed in the interval, and the remainder is the cycle for the given year: if nothing remains, the cycle is 19. Lastly, subtract 312 from the given year of Christ, and divide the remainder by 15, and what remains, after this division, is the Indiction for the given year: if nothing remains, the Indiction is 15.

*The Cycle of Easter*, also called the *Diomysian Period*, is a revolution of 532 years; found by multiplying the solar cycle 28, by the lunar cycle 19. If the new moons did not anticipate upon this cycle, Easter-day would always be the Sunday next after the full moon which follows the twenty-first of March; but, on account of the above anticipation, to which no proper regard was had before the late alteration of the style, the ecclesiastic Easter has several times been a week different from the true Easter, within this last century; which inconvenience is now remedied by making the table, which used to find Easter for ever, in the Common Prayer Book, of no longer use than the lunar difference from the new style will admit of. The earliest Easter possible, is the 22d of March; the latest, the 25th of April. Within these limits are thirty-five days, and the number belonging to each of them is called the Number of Direction; because, thereby, the time of Easter is found for any given year.

**CYCLOGRAPH,** an instrument, as its name imports, used for describing the arcs of circles, in some cases where compasses cannot be employed.

The most simple cyclo-graph, next to the compasses, is that commonly used by artificers in describing arches for the tops of doors, windows, &c. DCE represent two rods, forming any determined angle at C; A and B are two fixed pins or nails, between which the cyclograph DCE is made to move, keeping both legs in constant contact with those points; so will the angle C describe the arch of a circle, as is obvious, because all angles in the same segments are equal to each other; and, therefore, conversely, if the angles be equal, the curve is the arc of a circle.

CYCLOID, (in Geometry,) or TROCHOID, a mechanical or transcendental curve, possessing several very curious properties, the generation of which will be understood from the following figure. Conceive the circle EPE to rotate along the right line AB, in the same plane with the circle, until a fixed point P in the circumference, which at first touched the right line at A, touches it again at B, after an entire revolution; then the curve ACB, traced upon the plane by the point P, is called a cycloid.

The line AB is called the *base*, and DC the *axis* of the cycloid; and the circle EPE the *generating circle*.

If the point P be without the circumference of the generating circle, then the curve described by that point is properly called a *trochoid*, but commonly also a *curtate cycloid*.

And if the point P be within the circumference of the generating circle, then the curve is called the *prolate cycloid*.

If the generating circle, instead of revolving along a right line, as in the above figures, is made to revolve along either the concave or convex circumference of another circle, then the curve so generated is called an *EPICYCLOID*; the principal properties of which will be found under that article. The cycloid is a modern curve, the invention of which has been attributed to Bovillus, who wrote about the year 1501.

We cannot, in this place, enter into an investigation of the several curious properties which belong exclusively to the cycloid, as this would occupy much more space than can with propriety be allotted to this article; we must, therefore, content ourselves with enumerating the principal of them.

*Properties of the Cycloid.*—Draw any right ordinate FGH, fig. 1. above, join CG, and from H draw HI parallel to CG, meeting the axis DC produced in I. Then, 1. IH is a tangent to the cycloid at the point H. 2. The circular arc CG is equal to the right line HG. 3. The semi-circumference CGD = semi-base DB. 4. The cycloidal arc CH = double the chord CG. 5. The semi-cycloidal arc CB = double the diameter CD. 6. The area of the cycloid ACBA = triple the area of the circle CGD. 7. The three spaces ACD, the circle CGD, and CBD, are equal to each other. 8. The upper segment of a cycloid cut off by a line parallel to the base, at  $\frac{1}{4}$  of the axis from the vertex, is equal to the regular hexagon inscribed in the generating circle. 9. The solid generated by the revolution of the cycloid about its base AB, is, to its circumscribing cylinder, as 5 to 8. 10. The solid generated about the tangent parallel to the base, is, to its circumscribing cylinder, as 7 to 8. 11. And the solid generated about the tangent parallel to the axis, is, to its circumscribing cylinder, as 6 to 8.

CYCLOPTERUS, the *Sucker*, a genus of fishes belonging to the order of amphibia nantes, of which there are three species, 1. The lumpus or lump fish, is in length nineteen inches, and weighs seven pounds. These fish abound in the Greenland seas, and on the coast of Scotland. 2. The liparis or sea snail, of a soft unctuous texture, and soon melts away, is in length five inches, and the colour a pale brown. 3. Cyclopterus minor, or the lesser sucking fish, is found on the coast of Britain. It is about four inches, and fastens very tenaciously to stones and rocks.

CYDER. We have already treated of CIDER, and as the two modes of spelling this word frequently occur, we have taken leave, under the present orthography, to insert some directions which may prove useful, in those families and countries where cyder is a common drink. Let your fruit be as near the same ripeness as possible, otherwise the juice will not agree in fermenting. When they are properly sweated, grind and press them; and as soon as you have filled a cask, if a hogshead, which is one hundred and ten gallons, ferment it as follows; and if less, proportion the ingredients to your quantity.

*A Ferment for Cyder.*—To one hogshead of cyder, take three pints of solid yeast, the mildest you can get; if rough, wash it in warm water, and let it stand till it is cold. Pour the water from it, and put it in a pail or can; put to it as much jalap as will lay on a sixpence, beat them well together with a whisk, then apply some of the cyder to it by degrees till your can is full. Put it all to the cyder, and stir it well together. When the ferment comes on you must clean the bung-holes every morning with your finger, and keep filling the vessel up. The ferment for the first five or six days will be black and stiff; let it stand till it ferments white and kind, which it will do in fourteen or fifteen days; at that time stop the ferment, otherwise it will impair its strength.

*To stop the Ferment.*—In stopping this ferment, which is a very strong one, you must first rack it into a clean cask, and when pretty near full, put to it three pounds of coarse, red, scowering sand, and stir it well together with a strong stick, and fill it within a gallon of being full; let it stand five or six hours, then pour on it as softly as you can a gallon of English spirit, and bung it up close; but leave out the vent-peg a day or two. At that time just put it in the hole, and close it by degrees till you have got it close. Let it lay in that state at least a year; and if very strong cyder, such as stire, the longer you keep it the better it will be in the body; and when you pierce it, if not bright, force it in the following manner.

*A Forcing for Cyder.*—Take a gallon of perry or stale beer, put to it one ounce of isinglass, beat well, and cut or pulled to small pieces; put to it the perry or beer, and let it steep three or four days. Keep whisking it together, or else the glass will stick to the bottom, and have no effect on the liquor. When it comes to a stiff jelly, beat it well in your can with a whisk, and mix some of the cyder with it till you have made the gallon four; then put two pounds of brick rubbings to it, and stir it together with two gallons of cyder more added to it, and apply it to the hogshead; stir it well with your paddle, and shive it up close. The next day give it vent, and you will find it fine and bright. If you force perry, cut your isinglass with cyder or stale beer, for no liquor will force its own body.

*To cure Acid Cyder.*—It is always to be observed, that even weak *alkalies* cure the strongest acid, such, for instance, as calcined chalk, calcined oyster or scallop-shells, calcined eggshells, alabaster, &c. But if a hogshead can soon be drank, use a stronger *alkali*, such as salt of tartar, or salt of wormwood; but in using them you must always preserve their colour with *lac*, or else the *alkali* will turn the liquor black, and keep it foul.

To one hogshead, take two gallons of *lac*\*, and put to it one ounce and a half of isinglass, beat well, and pulled small; boil them together for five or six minutes; strain it, and when a stiff jelly, break it with a whisk, and mix about a gallon of the cyder with it; then put three pounds of calcined chalk, and two pounds of calcined oyster-shells to it, whisk it well together with four gallons more of the cyder, and apply it to the hogshead. Stir it well, and it will immediately discharge the acid part out at the bung. Let it stand one hour, then bung it close

\* *Lac* is milk, but the cream must be skimmed off it for use.

for five or six days; rack it from the bottom into a clean hogshead, and apply one quart of forcing to it. If you use a strong *alkali*, put to the *lac* four ounces of salt of tartar, or salt of wormwood; but the former is best, as it hath not the bitter taste in it which the wormwood has.

*To cure Oily Cyder.*—The reason that cyder is sometimes oily, is owing to the fruit not being sorted alike; for the juice of fruit that is not ripe will seldom mix with ripe juice in fermentation. The acid part of one will predominate over the other, and throw the oily particles from it, which separation gives the liquor a disagreeable, foul taste; to remedy which, you must treat it in the following manner, which will cause the oily parts to swim at top, and then you may rack the liquor from its bottom and oil.

To a hogshead, take an ounce of salt of tartar, and two ounces of half sweet spirit of nitre, mix them in a gallon of *lac*, and whisk them well together; apply it to the hogshead, bung it up, and let it stand ten or fifteen days; then put a cock within two inches of the bottom of the hogshead, and rack it.

Observe when it runs low to look to the cock, lest any of the oily part should come, which will be all on the top, and will not run out till after the good liquor is drawn off.

Put to the clean a quart of forcing, to raise it, and bung it close.—When you take out the oil and bottom, your cask must be well fired, otherwise it will spoil all the liquor that shall be afterwards put into it.

*For Ropy Cyder.*—The following remedy for ropy cyder must be proportioned with judgment to the degree of the disorder in the liquor. If the rope be stiff and stringy, you must use a larger quantity of the ingredients.

If a hogshead be quite stiff and stringy, work it at least an hour with your paddle, then put to it six pounds of common alum, ground to a fine powder; work it for half an hour after, and bung it up close. This in a week will cut the rope, and bring it to a fine, thin, fluid state. Then rack it into a clean hogshead, and put to it one quart of forcing; stir them well in the hogshead, and bung it close up. If but a thin rope, use a less quantity of the alum, and work it the same way.

*Cyders bad-flavoured.*—Some cyders in keeping are apt to get reasty, through the ill quality of the fruit; and sometimes through the badness of the cask will get musty, or fusty.

To remedy these evils, you must throw it in ferment, if its body is strong, with yeast and jalap, and let it ferment three or four days; which will throw off the greatest part of the taste; then stop the ferment. If a hogshead, put to it one pound of sweet spirit of nitre, and bung it up close. This will cure the bad flavour, if any be left, and likewise keep it from growing flat.

*To colour Cyder.*—In many places, particularly where the soil is light, and the orchard lies rising, the juice of the fruit is nearly white, and though the cyder may be strong, it does not appear to be so by reason of its colour, which always prejudices the buyer against it.

Many people spoil a great deal of good cyder by boiling and mixing molasses with it, to give it a colour which not only gives it a bad red colour, but makes it muddy as well as bad-tasted. Others again will boil a large quantity of brown sugar, and mix with it, which gives it a colour indeed, though a light one; when two pounds of good sugar, properly used, is sufficient to colour ten hogsheads, as follows:

Take two pounds of powder sugar, the whiter the sugar the farther it will go, and the better the colour will be. Put it in an iron pot or ladle; set it over the fire, and let it burn till it is black and bitter; then put two quarts of boiling hot water to it; keep stirring it about, and boil it a quarter of an hour after you have put the water to it. Take it off the fire, and let it stand till it is cold, then bottle it for use.

Half a pint of this will colour a hogshead. Put to each half-pint, when you use it, a quarter of an ounce of alum ground, to set the colour.—See CIDER.

**CYDONIA**, the *Quince*, so called from Cydon in Crete, which abounds with this fruit. The species are, 1. The oblonga, with an oblong fruit, lengthened at the bases. 2. The maliforma with oval leaves, woolly on the upper side. The most valuable is that called the *Portugal quince*, the pulp of which turns to a fine purple, and makes a good marmalade.

**CYGNUS**, is fabled by the Greeks to be the *Swan*, under the form of which Jupiter deceived Leda or Nemesis, the wife of

Tyndarus, king of Laconia. Leda was the mother of Pollux and Helena, the most beautiful woman of her age, and also of Castor and Clytemnestra. The two former were deemed the offspring of Jupiter, and the others claimed Tyndarus as their father. According to another fable, Orpheus, the celebrated musician of antiquity, having been killed by the cruel priestess of Bacchus, the gods metamorphosed him into a *Swan*, and placed him among the stars by the side of his lyre.

*Boundaries and Contents.*—Cygnus is situated in the Milky Way, and is bounded on the north by Draco, east by Lacerta and Pegasus, south by Vulpecula et Anser, and west by Lyra. There are eighty-one stars in this constellation, viz. one of the 1st or 2d magnitude, six of the 3d, twelve of the 4th, &c. The most brilliant star in Cygnus is called *Deneb*, whose right ascension is  $308^{\circ} 49' 19''$ , and its descension  $44^{\circ} 38' 32''$  north. The greater part of this constellation never sets in lat.  $51^{\circ}$  north, and *Deneb* culminates at London, for the first day of every month, as in the following table: Meridian Altitude,  $83^{\circ} 7' 32''$ .

| MONTH. | CULM.<br>ho. mi. | MONTH. | CULM.<br>ho. mi. | MONTH. | CULM.<br>ho. mi. |

**CYLINDER**, is a solid having two equal circular ends parallel to each other, and every plane section parallel to the ends is also a circle, and equal to them. Cylinders are either *right* or *oblique*.

A *Right CYLINDER*, is that whose side is perpendicular to the plane of its base, as the figure ABCD fig. 1.

An *Oblique CYLINDER*, is that whose side is not perpendicular, but oblique to the plane of its base, as LMNO, fig. 2. A right cylinder may be conceived to be generated by the revolution of a rectangle, as PBDQ, about one of its sides PQ, which remains fixed, and which is called the axis of the cylinder. Or we may otherwise conceive it to be generated by carrying a right line parallel to itself, about the circumferences of two equal and parallel circles; which answers as well for the oblique, as for the right cylinder.

*To find the Surface and Solidity of a Cylinder, whether right or oblique.*—1. Multiply the circumference of its base by its length, and the product will be the area. 2. Multiply the area of its base by its perpendicular height, and the product will be the solidity.

**CYLINDRIC**, or **CYLINDRICAL**, any thing relating to the cylinder. **CYLINDRIC Ring**, is a solid which may be conceived, by supposing a cylinder to be bent round into a circular form, so as to return upon itself.

*To find the Surface and Solidity of a Circular Ring.*—1. Multiply the circumference of a perpendicular section of the ring, by half the sum of the inward and outward diameters, and that product again by 3.1416, and the last product will be the surface of the ring. 2. Multiply the area of a perpendicular section by the same quantities, and the last product will be the solidity.

**CYMATIUM**, in Architecture, a member or moulding of the cornice, the profile of which is concave at the top and convex at the bottom.

**CYMBAL**, a musical instrument of antiquity. It was round, and made of brass like our kettle-drums, but smaller, and applied to a different use.

**CYNARA**, the *Artichoke*, a genus of the polygamia aequalis order, and of the syngenesia class of plants. There are four species, but only two are cultivated for use. The garden artichoke, which is either the conical green-headed French artichoke, or the globular-headed red Dutch artichoke; and the cardoon, which is larger than the preceding. The former is propagated by slips or suckers, and the latter by seed.

Fig. 1.

Fig. 2.

**CYNICS**, a sect of ancient philosophers, who valued themselves upon their contempt of riches and state, arts and sciences, and every thing, in short, except virtue or morality.

**CYNIPS**, a genus of insects of the order of hymenoptera, of a bright brown colour, and produced in the hard galls under the oak leaves, being deposited there by the gall-fly. The oak-bud cynips is of a shining green colour, and there are nineteen species of this insect.

**CYPERUS**, a genus of the monogynia order, in the triandria class of plants, ranking in the natural method under the 3d order, calamariæ, of which there are fifty-three species, the principal of which are the round, the long sweet cyperus, and the papyrus. The long cyperus is used by perfumers and glovers. The papyrus is celebrated for its early use as paper.

**CYPHER**, or **CIPHER**. To write in cypher denotes the art of communicating by writing in such a manner as shall be legible only to those who are acquainted with the rules by which the characters made use of are formed or disposed. It is principally used in diplomatic correspondence, or on other national affairs, such as those relating to the operations of war. As the nature of alphabetic writing, and the structure of languages, necessarily imply certain indispensable habitudes of the letters and words, it often happens that the laws or conditions made use of for the sake of secrecy can be detected by skilful persons, and the secret by that means discovered. The art of discovering the sense of writings of the description here mentioned, is called *decyphering*.

**CYPRÆA**, or **COWRIE**, a genus of insects of the order of vermes testaceæ. It is of the snail kind; and there are forty-four species, distinguished by the form of their shells, which are used as money in Bengal and on the coast of Guinea.

**CYPRESS**. See **CUPRESSUS**.

**CYPRINUS**, a genus of fishes of the order of abdominales, of

which there are thirty-one species, as, 1. The carp, found in the rivers and lakes of Polish Prussia, &c. Carp is a long-lived fish, and instances are related of some that have attained the age of 100 years. The carp is very cunning, and on that account is called the river fox. It is very shy in taking a bait, but in spawning time it is easily caught. In Prussia, carp are often kept some time out of water, and grow fat in their new element. They are suspended in a net in a cellar, and plunged in water every four or six hours. 2. The barbel, a coarse fish, whose roe is so noxious as to produce vomiting, purging, and a swelling in those who unwarily eat of it. The barbel is about three feet long, and the dorsal fin is armed with a strong spine, with which it inflicts a dangerous wound. 3. The tench, reckoned a delicious food in this country, weighs generally 4 or 5lbs. and is thick and short. The colour of the back is dusky, but the head, sides, and belly are greenish with a mixture of gold. 4. The gudgeon, found in gentle streams, seldom weighs more than half a pound. 5. The bream, which inhabits lakes or the deep parts of still rivers, is an insipid fish. 6. The roach is a common river fish, never exceeding five pounds. 7. The dace, also common, and a great breeder, is often seen in the summer frolicking on the water. The general weight is less than 2lbs. 8. The cephalus or chub, is a coarse bony fish, that frequents the deep holes of rivers. 9. The bleak, is common in many rivers. At some seasons they are so much agitated as to be called mad-bleak by the fishermen. It is supposed that this is occasioned by a hair-worm, which attacks them, and of which they die. Artificial pearls are made of the scales of this fish, and also of those of the dace. The usual length of the bleak is two inches. 10. The gold fish, a small beautiful species, domesticated in China, and much valued as an ornament for courts and gardens. The gold and silver fish were introduced into England generally in 1723.

## D.

### D A M

**D**, the fourth Letter of the Alphabet, and as a numeral denoting 500, with a dash over it,  $\overline{D}$  5000. In abbreviation it has various significations, as D.D. doctor in divinity; M.D. doctor in medicine. In Music, D marks in thorough bass what the Italians call *descanto*, denoting that the treble ought to play alone, as T does the tenor, and B the bass. DC means the abbreviation of *de capo*, or from the head.

**DÆMON**, a name given to certain spirits, or genii, which, it is said, appeared to men.

**DAIRY**, in rural affairs, a place appointed for the management of milk, and the making of butter, cheese, &c. Dairy-houses are to be kept perfectly clean; and lattices are to be preferred to windows; and if their situation can be fixed beside a spring or current of water, it is to be preferred. The proper receptacles for milk are earthen pans, or wooden vats, and lead should not be used on any account, as it is highly poisonous, unless the greatest care be used to scald it daily.

**DAMAGE**, in Law, is generally understood of a hurt or hinderance attending a person's estate; but in Common Law, it is a part of what the jury are to inquire into, relative to the plaintiff or defendant.

**DAMAGE faisant**, is where the beasts of another come upon a man's land and spoil his corn or grass, in which case the owner may impound them till satisfaction be obtained.

**DAMASK**, a sort of silken stuff, both in warp and woof; or with the warp silk, and the woof thread; or all thread, or all wool. And *Damaskeening* is the art of beautifying iron, or steel, by inlaying it with gold or silver wire, as in sword blades, guards, and gripes, locks of pistols, &c. Were the artists of Britain to turn their attention to this subject, they might soon rival all other countries in the world in damaskeening steel.

**DAMPS**, noxious exhalations issuing from the earth, and which almost instantly prove fatal to those who breathe them.

### D A Y

We allude here chiefly to *coal mine damp*s, called *choke* and *fire damp*s; the former is *carbonic acid gas*, generally prevalent in wastes, or neglected works; the latter is *hydrogen gas*, or inflammable air. See *Safety Lamp*.

**DARK RAYS**, in Philosophy, are certain emanations from the sun, that have been recently discovered, which are not perceptible to our eyes, and are only manifested by their effects on the thermometer. Thus when the rays of the sun are refracted by a glass prism, and form the coloured spectrum upon any surface, a thermometer placed beyond the spectrum is elevated by the heat of certain rays, or emanations, which are by no means visible; and which have thence been denominated *calorific rays*.

**DATA**, in Mathematics, denote certain quantities which are given or known, and by means of which other quantities, which are unknown, are to be determined. Euclid, in his book of "Data," uses this term to denote such spaces, lines, angles, &c. as are given, or to which others may be found equal.

**DATE**, in Law, the description of the day, month, year of our Lord, and year of the king in which a writing is made. In writings of importance, the date should be in words at length. An *ante-date* is that prior to the real time when the instrument was signed. A *post-date* is that which is posterior to the real time.

**DAY**, in Astronomy, is that portion of time which elapses between two successive transits of the sun over the same meridian; and the time is reckoned from noon to noon, and consists of twenty-four hours. This is called a *natural day*, being of the same length in all latitudes. The *artificial day* is the time elapsed between the sun's rising and setting, and is variable according to the different latitudes of places.

A *mean Solar Day* is measured by equal motion, as by a clock or timepiece, and consists of twenty-four hours. There are, in the course of a year, as many mean solar days as there

are true solar days, the clock being as much faster than the sun-dial on some days of the year, as the sun-dial is faster than the clock on others. Thus the clock is faster than the sun-dial from the twenty-fourth of December to the fifteenth of April, and from the sixteenth of June to the thirty-first of August; but from the fifteenth of April to the sixteenth of June, and from the thirty-first of August to the twenty-fourth of December, the sun-dial is faster than the clock. When the clock is faster than the sun-dial, the true solar day exceeds twenty-four hours; and when the sun-dial is faster than the clock, the true solar day is less than twenty-four hours; but when the clock and the sun-dial agree, *viz.* about the fifteenth of April, sixteenth of June, thirty-first of August, and twenty-fourth of December, the true solar day is exactly twenty-four hours.

*Days of the Week.*—These are Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday.

*The Nautical Day* commences, either by observation or account, when the sun is on the meridian, which is generally supposed to be our 12 o'clock at noon on shore. At that moment, the officer of the watch, or more commonly the master of the ship, orders the marine sentinel to turn a half-hour sand glass, which he has always in charge, which has been previously run out, and *strike eight bells forward*; which is accordingly done, and the dinner is piped. No sooner is this glass run out, than the sentinel calls, "Strike the bell *one*, forward;" and again turns it, when the grog is immediately piped. When it runs out a second time, he again calls, "Strike the bell *two*, forward;" which is no sooner done, than the boatswain's mate calls the afternoon watch. Thus he proceeds until he comes to the *eighth* bell, which is no sooner struck, than the watch expires, and the grog is again piped. Previous to this, however, in order to relieve the quartermaster, the helmsman, the look-out at the mast head, and the sentinel at the glass, an individual of each of these classes of the watch below, goes, when the seventh bell is struck, to the purser's steward, gets his quarter of grog unmixed, takes his supper, and is ready, as soon as the 8th strikes, to relieve his man with the rest of the watch. All hands now take supper; and when one bell again strikes, the first *dog watch* is called. This is only a watch of two hours; and accordingly when the 4th bell has struck, the second *dog watch* is called, which lasts other two hours, and brings the supposed time pretty accurately to our eight o'clock at night. By this time, however, the hammocks having been piped down, the watch relieved generally retires to rest. The watch on deck, therefore, execute all the necessary duties of the ship until their 8th bell is struck; when the *middle watch* is called; and these again are relieved in the same time by the *morning watch*, who do the ship's duty during other eight bells, which brings the time to our eight o'clock in the morning, when breakfast is always piped. As usual at *one bell*, the forenoon watch is called, who do the duties of the deck while the watch below are fumigating or scrubbing the lower deck, or probably mending their clothes; and thus they continue until the *observation of the sun at noon* is again taken, if the weather is favourable, and any necessary correction made on the time lost or gained. When the *eighth* bell is once more struck, the *day at sea* is completed, the glass is turned to commence a new one, the dinner is piped, and the watch called as before.

*DAYS of Grace*, in Commerce, are those allowed for the payment of a bill of exchange after the sum becomes due. In England they are three.

*DAYS WORK*, the reckoning or account of a ship's course or distance run during 24 hours, or from noon to noon, according to the rules of TRIGONOMETRY.

*DAVIT*, a strong beam of timber used as a crane, whereby to hoist the flukes of the anchor to the top of the bow, without injuring the planks of the ship's side as it ascends; an operation which, by seamen, is called fishing the anchor; the lower end of the davit rests on the fore chains, the upper end being properly secured by a tackle from the mast head; upon the other end is hung a large block, through which a strong rope is reeved, called the fish-pendant, to whose outer end is fitted a large hook, and to its inner end a tackle; the former is called the fish-hook, the latter the fish-tackle. The anchor being first catted, the fish-hook is fastened on its flukes, and is, by means

of the fish-pendant and tackle, drawn up sufficiently high upon the bow to be made fall by the shank-painter. Thus the davit, according to the sea phrase, is employed to fish the anchor. There is also a davit of a smaller kind, occasionally fixed in the longboat, and, with the assistance of a small windlass, used to weigh the anchor by the buoy-rope, &c.

*DEACON*, one of the three holy orders of the church, being that next below the priesthood.

*DEAD EYE*, or *DEAD MAN'S EYE*, a sort of round flattish wooden block encircled with a rope, or with an iron band, and pierced with three holes through the flat part, in order to receive a rope called the laniard, which corresponding with three holes in another dead eye, creates a purchase employed for various uses, but chiefly to extend the shrouds and stays, otherwise called the standing rigging. In order to form this purchase, one of the dead eyes is fastened in the upper link of each chain on the ship's side, which is made round to receive and encompass the hollowed outer edge of the dead eye. After this the laniard is passed ultimately through the holes in the upper and lower dead eyes, till it becomes sixfold, and is then drawn tight by the application of mechanical powers. In merchant ships they are generally fitted with iron plates, in the room of chains. The dead eyes used for the stays have only one hole, which, however, is large enough to receive ten or twelve turns of the laniard; these are generally termed *Hearts*. The crowfeet *Dead Eyes*, are long cylindrical blocks, with a number of small holes in them, to receive the legs, or lines, of which the crow foot is composed.

*DEAD LIGHTS*, strong wooden ports made exactly to fit the cabin windows, in which they are fixed on the approach of a storm, the glass frames being taking out, which would otherwise be shattered by the violence of the waves, and let great quantities of the water pour into the ship.

*DEAD RECKONING*, the judgment or estimation which is made of the place where a ship is situated, without any observation of the heavenly bodies; it is discovered by keeping an account of the distance she has run by the log, and of her course steered by the compass, and by rectifying these data by the usual allowances for drift, leeway, &c. according to the ship's known trim; this reckoning is, however, always to be corrected as often as any good observation of the sun can be obtained.

*DEAD RISING*, or *RISEING LINE* of the floor, those parts of a ship's floor or bottom throughout her whole length, where the floor timber is terminated on the lower futtock.

*DEAD ROPES*, are those which do not run in any block.

*DEAD WATER*, the eddy of water which appears like little whirlpools closing in with the ship's stern as she sails through it.

*DEAD WOOD*, in Naval Architecture, certain blocks of timber laid upon the keel, particularly at the extremities afore and abaft, where these pieces are placed upon each other to a considerable height, because the ship is there so narrow as not to admit of the two half timbers, which are therefore scored into this dead wood, when the angle of the floor timbers gradually diminishes as approaching the stem and stern post. In the fore part of the ship, the dead wood generally extends from the stemson, upon which it is scarfed, to the loof frame; and in the after end from the sternpost, where it is confined by the knee to the after balance-frame. It is connected to the keel by strong spike nails. The dead wood afore and abaft is equal in depth to two-thirds of the depth of the keel, and as broad as can be procured, so as not to exceed the breadth of the keel.

*DEAD WORKS*, all that part of the ship which is above water when she is laden. The same as *UPPER WORK*.

*DEAFNESS*, the want of the sense of hearing, arising either from an obstruction or a compression of the auditory nerves, or from some collection of matter in the cavities of the inner ear, or from the auditory passage being stopped by some hardened excrement; or, lastly, from some excrescence, a swelling of the glands, or some foreign body introduced within the ears. Persons born deaf are also dumb.

*DEAL*, a plank of fir, made by sawing the trunk of the tree longitudinally. Deals are hardened by throwing them into salt water as soon as they are sawed, and keeping them therein some days, and then drying them in the sun.

**DEAN**, an ecclesiastical dignitary next to the bishop, and head of the chapter in a cathedral church. There are deans also who have no chapters, as the dean of Battle, the dean of Bocking, &c. Rural deans have no judicial authority, but a right of visiting churches within their district, and reporting the condition of the same to the ordinary.

**DEAN** and *Chapter*, are the bishop's council to assist him in the affairs of religion, and to assent to every grant which the bishop shall make to bind his successors. As a deanery is a spiritual dignity, hence a man cannot be a dean and prebendary of the same church.

**DEATH**, physically, the extinction of animal life. In Law, there is a natural death and a civil death; the former where a person actually dies, the latter where he is adjudged to be so in law. Thus if a person, for whose life an estate is granted, is absent seven years, and there is no proof of his being living, he shall be accounted as dead.

**DEATH-WATCH**, a small insect which makes a ticking noise like the beating of a watch. There are two species, one of a dark brown colour, spotted, having pellucid wings under the vagina, a cap on the head, and two antennæ proceeding from beneath the eyes. The noise which it makes is a signal between the male and female. The second kind is a small grayish insect, much like a louse when viewed with the naked, unassisted eye.

**DEBENTURE**, a Custom-house certificate delivered to the exporter of goods, by virtue of which he is entitled to a bounty or drawback.

**DEBT, NATIONAL**, the engagement entered into by a government, to repay at a future period money advanced by individuals for the public service, or to pay the lenders an equivalent annuity. National debts have arisen from the necessity of obtaining larger sums of money than could be raised at the time they were wanted by direct contributions; and often, when it would have been absolutely impossible to raise the requisite sum if a heavy tax had been imposed, and strictly levied, it has been deemed more prudent to avoid the evils attendant on such a measure by the less obnoxious expedient of a loan. In most countries, the subordinate governors, to whom is generally consigned the task of providing for the public expenses, being desirous of popularity, have shewn a great predilection for this mode of obtaining money, as it enables them to support a profuse expenditure, without appearing to oppress the people in so great a degree as they otherwise must: the system of getting into debt, or the funding system, as it is generally called, from particular funds being usually appropriated for payment of interest on the debts contracted, has therefore been adopted by most of the states of Europe, by many of the colonies, and by the American republics.—*WATKINS' Cyclopædia*.

**DECACHORDON**, a musical instrument like the harp with ten strings, called by the Hebrews nasur.

**DECAGON**, a plane geometrical figure, of ten sides and ten angles. When all the sides and angles are equal, it is a regular decagon, and may be inscribed in a circle; otherwise not. If the radius of a circle, or the side of the inscribed hexagon, be divided in extreme and mean proportion, the greater segment will be the side of a decagon inscribed in the same circle. And, therefore, as the side of the decagon is to the radius, so is the radius to the sum of the two.

**DECEMBER**, *THE BOTANICAL KALENDAR FOR*, instructs us that the gardener's operations are chiefly of the laborious kind; but long nights and short days give him ample leisure for study, unless he be of the slovenly tribe of gardeners, whose minds resemble their gardens, and are known rather by the excellence and growth of the weeds, than by order, regularity, progress, and scientific reputation.

*In the Kitchen Garden*, this month sow peas, beans, and radishes; but consider the result uncertain. Protect beans, transplant cabbages; earth up peas and beans; cover their stems with ashes, sawdust, or old tan. Tie up endive; weed and hoe; tie up esculents, as borecoles; destroy slugs, snails, mice; and fill the ice-house.

*In the hardy Fruit Department*, we plant the apple, pear, gooseberry, currant, &c. in mild weather; and all trees not pruned in November are now to be pruned. In the routine of

culture, trench, dig, and ridge up in dry weather. Exhausted soils must now be recruited; larvæ of moths must be destroyed; and the temperature of the fruit cellars must be kept from 30° to 40°.

*In the culinary Hot-house Department*, sow small sallads, give abundance of air in dry weather, but protect in frosts. Begin to force asparagus, prepare cucumber beds; keep a steady heat in the pinery; and let the forcing houses be regularly attended to.

Little is done in the flower department this month, except in a liberal use of ashes, tan, &c. to bulbs, hydrangeas, &c. Attend to alpinæ, florists' flowers, annuals, &c. In the green-house the lowest temperature must be 42°, the highest 46°. The dry stove may average from 45° to 50°. But the back stove must average from 55° to 58°.

*In the Pleasure Ground and Shrubbery*, plant, prune, protect according to the weather; repair walks, roll them; sweep and clean lawns, lay down turf; and fell all trees that are to be removed as useless, or for their timber and bark.

**DECEMVIRI**, ten magistrates chosen yearly at Rome to govern the commonwealth instead of consuls.

**DECIDUOUS**, in Botany, a term expressive of the second stage of duration in plants, but susceptible of different senses, according to the particular part of the plant to which it is applied. A leaf is said to be deciduous which drops in autumn; petals are deciduous which fall off with the stamina and pistillum; and this epithet is applied to such flower-cups as fall after the expansion, and before the dropping of the flower.

Most plants in cold and temperate climates shed their leaves yearly. This happens in autumn, and is generally announced by the flowering of the common meadow saffron. The term is only applied to trees and shrubs; for herbs perish down to the root every year, losing stem, leaves, and all. All plants do not drop their leaves at the same time. Among large trees, the ash and walnut, although latest in unfolding, are soonest divested of them: the latter seldom carries its leaves above five months. On the oak and horn-beam the leaves die and wither as soon as the cold commences; but remain attached to the branches till they are pushed off by the new ones, which unfold themselves the following spring. These trees are doubtless a kind of evergreens; the leaves are probably destroyed only by cold; and, perhaps, would continue longer upon the plant, but for the force of the spring-sap, joined to the moisture.

With respect to the deciduous trees, the falling off of the leaves seems principally to depend on the temperature of the atmosphere, which likewise serves to hasten or retard the appearance in question. An ardent sun contributes to hasten the dropping of the leaves. Hence, in hot and dry summers, the leaves of the lime-tree and horse-chestnut turn yellow about the 1st of September; whilst, in other years, the yellowness does not appear till the beginning of October. Nothing, however, contributes more to hasten the fall of the leaves than immoderate cold or moist weather in autumn; moderate droughts, on the other hand, serve to retard it. It deserves to be remarked, that an evergreen tree grafted upon a deciduous, determines the latter to retain its leaves. This observation is confirmed by repeated experiments, particularly by grafting the laurel, or cherry-bay, an evergreen, on the common cherry; and the ilex, or evergreen oak, on the oak.—*WATKINS' Cyclopædia*.

**DECIES TANTUM**, in Law, a writ that lies against a juror, who has been bribed to give his verdict.

**DECIMAL**, *ARITHMETIC*, (*Decimal Tenths*), in a general sense, denotes the common arithmetic, in which we count by periods of tens; and is otherwise, and more properly, called *Denary Arithmetic*, to distinguish it from the *Binary*, *Duodenary*, and other scales of arithmetic.

**DECIMAL Fraction**, is a fraction having always some power of 10 for its denominator, which consists of either 10, 100, 1000, &c. denoting the number of equal parts into which the integer or whole is supposed to be divided, as  $\frac{2}{10}$ ,  $\frac{13}{100}$ ,  $\frac{17}{1000}$ , &c. But, for the sake of brevity, the numerator only is expressed, like a whole number with a point on the left of it, as .2, .02, .002, &c. and which must always consist of as many figures as there are ciphers in the denominator; the places between the significant figures and the point being supplied with ciphers, when neces-

sary, as above. Consequently, the same number of figures on the right of the decimal point, has always the same denominator. Thus, the denominator of the fractions  $\cdot 5000$ ,  $\cdot 0746$ ,  $\cdot 0005$ , is 10000. And hence, it appears, that the value of a decimal fraction is not altered by ciphers on the right hand; for  $\cdot 5000$  (or  $\frac{5000}{10000}$ ) when reduced to its lowest terms is the same as  $\cdot 5$ , each being equal to  $\frac{1}{2}$ . In mixed numbers the decimals are separated from the integers by a point, thus,  $25\frac{2}{100}$  is written  $25\cdot 02$ . It is also evident, that the value of decimals decreases in the same tenfold proportion from the point towards the right hand, as that of integers increases towards the left.

**DECKER**, relates to the rate of a ship of force, as a two-decker, a three-decker, *i. e.* carrying two entire tiers or ranges of cannon, or three such tiers.

**DECKS**, the planked floors of a ship, which connect the sides together, and serve as different platforms to support the artillery and lodge the men, as also to preserve the cargo from the sea and rain. As all ships are broader at the lower deck than on the next above it, and as the cannon thereof are always heaviest, it is necessary that the frame of it should be much stronger than that of the others; and for the same reason, the second or middle deck ought to be stronger than the upper deck or fore-castle.

Ships of the first and second rate are furnished with three whole decks, reaching from the stem to the stern, besides a fore-castle and a quarter deck, the former extending aft from the stem to the belfry, and the latter forward from the stern to the mainmast, a vacancy being left in the middle, which opens to the upper deck, and forms what is called the waist; there is yet another deck above the hinder part of the quarter deck called the poop, which also serves as a roof for the captain's cabin or couch; and another deck below the lower gun-deck called the orlop, whereon the cables are coiled and the sails stowed, &c. Other ships of the line, with 50-gun ships, and some of 40 guns, have two gun-decks and a quarter deck, a fore-castle, a poop, and orlop. Frigates and sloops have one gun-deck, a half deck, and fore-castle, with a spar deck below to lodge the crew, but no poop; brigs, cutters, and such small vessels, have no half deck or fore-castle, and are then said to be flush fore and aft; the decks are formed of, and sustained by, the beams, the clamps, or water-ways, the carlings, the ledges, the knees, and two rows of small pillars called stanchions, &c. See those articles. The number of beams by which the decks of ships are supported, is often very different, according to the practice of different countries; the strength of the timber of which the beams are framed, and the services for which the ships are calculated. The deck which contains the train of a fire-ship is furnished with an equipage peculiar to itself, a description of which will be found under the article **FIRE-SHIP**. Flush deck, or deck flush fore and aft, implies a continued floor laid from stem to stern, upon one line, without any stops or intervals. Half deck, the under part of the quarter deck of a ship of war, contained between the foremost bulk head of the cabin or wardroom, and the break of the quarter deck. In the colliers of Northumberland, the steerage itself is called the half deck, and is usually the habitation of the ship's crew. The main deck is that part of the upper deck which extends from the break of the fore-castle to the break of the quarter-deck; also called the waist.

**DECLARATION**, in Law, a written exposition of the matter of complaint, made by the plaintiff against the defendant.

**DECLINATION OF THE SUN**, of a *Star*, or a *Planet*, is its distance from the equinoctial, northward or southward. When the sun is in the equinoctial, he has no declination, and enlightens half the globe from pole to pole. As he increases in north declination he gradually shines farther over the north pole, and leaves the south pole in darkness; in a similar manner, when he has south declination he shines over the south pole, and leaves the north pole in darkness:  $23^{\circ} 28'$  is the sun's nearest declination north or south. The declination of any heavenly body, as of a star, may be easily found by the following rule: Take the meridian altitude of the star, at any place where the latitude is known; the complement of this is the zenith distance, and is called north or south, as the star is north or south at the time of observation. Then, 1. When the latitude of the place, and zenith distance of the star, are of differ-

ent kinds, namely, one north and the other south, their difference will be the declination; and it is of the same kind with the latitude, when that is the greatest of the two, otherwise it is of the contrary kind. 2. If the latitude and the zenith distance are of the same kind, *i. e.* both north, or both south, their sum is the declination; and it is of the same kind with the latitude. Accurate tables of the sun's declination are published regularly in the nautical almanacks.

**Circles of DECLINATION**, are great circles of the sphere passing through the poles of the world, on which the declination is measured.

**Parallels of DECLINATION**, are small circles of the sphere parallel to the equator.

**Parallax, or Refraction of DECLINATION**, is such an arch of a meridian as is equal to the change produced in the declination by parallax or refraction, respectively.

**DECLINATION of a Vertical Plane or Wall**, in Dialing, is an arch of the horizon, comprehended either between the plane and the prime vertical, when it is counted from east to west, or between the plane and the meridian, when it is counted from north to south.

**DECLINATOR**, an instrument for determining the declination or inclination of reclining planes.

**DECLINERS, or DECLINING DIALS**, are those which cut either the plane of the prime vertical circle, or plane of the horizon, obliquely.

**DECLIVITY**, a sloping or oblique descent.

**DECOCTION**, in Pharmacy, the extracting of the virtues of simples and other drugs by boiling.

**DECOMPOSITION**, in Chemistry, the separation or dissolution of the constituent parts of bodies.

**DECORATION**, in Architecture, any thing that adorns and enriches a building, church, triumphal arch, &c. as the orders of architecture, paintings, vases, festoons, scenes, &c.

**DECOUPLE**, in Heraldry, the same as uncoupled, or parted.

**DECOY**, among fowlers, a place made for catching wild-fowl. A decoy is generally made where there is a large pond surrounded with wood, and beyond that a marshy and uncultivated country: if the piece of water is not thus surrounded, it will be attended with noises and other accidents which may be expected to frighten the wild-fowl from a quiet haunt, where they mean to sleep in the day-time in security. If these noises or disturbances are wilful, it has been held that an action will lie against the disturber. As soon as the evening sets in, the decoy rises, and the wild-fowl feed during the night. If the evening is still, the noise of their wings during their flight is heard at a very great distance, and is a pleasing, though rather melancholy, sound.

The decoy ducks are fed with hemp-seed, which is thrown over the screens in small quantities, to bring them forwards into the pipes or canals, and to allure the wild-fowl to follow, as this seed is so light as to float. There are several pipes, as they are called, which lead up a narrow ditch that closes at last with a funnel-net. Over these pipes (which grow narrower from their first entrance) is a continued arch of netting suspended on hoops. It is necessary to have a pipe or ditch for almost every wind that can blow, as upon this circumstance it depends which pipe the fowl will take to; and the decoy-man always keeps on the leeward side of the ducks, to prevent his scent reaching their sagacious nostrils. All along each pipe, at intervals, are placed screens made of reeds, which are so situated that it is impossible the wild-fowl should see the decoy-man before they have passed on towards the end of the pipe, where the purse-net is placed. The inducement to wild-fowl to go up one of these pipes is, because the decoy ducks, trained to this, lead the way, either after hearing the whistle of the decoy-man, or enticed by the hemp-seed; the latter will dive under water, whilst the wild-fowl fly on, and are taken in the purse. It often happens, however, that the wild-fowl are in such a state of sleepiness and dozing, that they will not follow the decoy ducks. Use is then generally made of a dog that is taught his lesson: he passes backwards and forwards between the reed screens (in which are little holes, both for the decoy-man to see, and the little dog to pass through;) this attracts the eye of the wild-fowl, who, not choosing to be interrupted, advance towards the small and contemptible animal, that they

may drive him away. The dog all the time, by the direction of the decoy-man, plays among the screens of reeds, nearer and nearer the purse-net; till at last, perhaps, the decoy-man appears behind a screen, and the wild-fowl not daring to pass by him in return, nor being able to escape upwards on account of the net-covering, rush on into the purse-net. Sometimes the dog will not attract their attention if a red handkerchief, or something very singular, is not put about him.—WATKINS' *Cyclopædia*.

**DECOY**, in Military affairs, a stratagem to carry off the enemy's horses in a foraging party, or from pasture. The word is also used to denote a stratagem employed by a small ship of war, to betray a vessel of the enemy within reach.

**DECREMENT**, in Heraldry, the wane of the moon from the full to the new, and when borne in coat armour, faces to the left side of the escutcheon, as that luminary does to the right side when in the increment.

**DECREPITATION**, in Chemistry, a term applied to the crackling noise of salts exposed to heat, by which they are quickly split. It takes place in those salts that have little water of crystallization, the increased temperature converting that small quantity into vapour, by which the crystals are suddenly burst. Common salt affords a good example of decrepitation, and when used as a flux should be previously decrepitated.

**DEDIMUS POTESTATEM**, in Law, a commission granted to one or more persons, to forward and despatch some act appertaining to a judge, or some court.

**DEED**, a written contract sealed and delivered. It must be written before the sealing and delivery, otherwise it is no deed; and after it is executed by the parties, nothing can be added, and therefore, if a deed is sealed and delivered with a blank left for the sum, which the obligee fills up after sealing and delivery, this will make the deed void.

**DEEP SEA-LINE**, or **DIP SEA-LINE**, in the sea-language, a small line to sound with; some a hundred and fifty fathoms long, with a plummet bollow at the head, and tallow put into it, to bring up stones, gravel, sand, shells, and the like, from the bottom, to know the differences of the ground.

**DEEP WAISTED**, the distinguishing fabric of a ship's decks, when the quarter deck and fore-castle are elevated from four to six feet above the level of the upper or main deck, so as to leave a vacant space, called the waist, on the middle of the upper deck.

**DE FACTO**, something actually fact, in contradistinction to *de jure*, where a thing is only so in justice, as a king *de facto* is a person in possession of a crown, but without a legal right to the same; and a king *de jure* is he who has just right to the crown, though he is out of possession.

**DEFAMATION**, the offence of speaking slanderous words of another; and where any person circulates any report injurious to the credit or character of another, the party injured may bring an action to recover damages proportioned to the injury he has sustained; but it is incumbent upon the party to prove that he has sustained an injury, to entitle him to damages. In some cases, however, as for words spoken which, by law, are in themselves actionable, as calling a tradesman a bankrupt, a cheat, or swindler, &c. there is no occasion to prove any particular damage, but the plaintiff must be particularly attentive to state words precisely as they were spoken, otherwise he will be nonsuited.

**DEFEASANCE**, in Law, a condition relating to a deed; as to a recognizance or statute, which being performed by the recognizor, the deed is defeated, and made void, as if it had never been done.

**DEFENCE**, in Law, a plea made by the defendant after the plaintiff's declaration, viz. that he defends all the wrong, force, and damages, where and when he ought, &c.

**DEFENDER OF THE FAITH**, a peculiar title given to the king of England by pope Leo the Tenth, to king Henry the Eighth, for writing against Martin Luther in behalf of the Church of Rome, then accounted *domicilium fidei catholicae*.

**DEFICIENT NUMBERS**, in Arithmetic, those whose parts or multiples added together fall short of the integer, of which they are the parts; such is 8, its parts, 1, 2, 4, making only 7.

**DEFILE**, in Military affairs, a narrow passage through which a company of horse and foot can pass only by making a small

front, so that the enemy may take an opportunity to charge them with so much the more advantage, as those in the front and rear cannot come to the relief of one another.

**DEFINITION**, an enumeration or specification of the simple ideas of which a compound idea consists, in order to ascertain its nature and character.

**DEFINITION**, in Rhetoric, a short comprehensive explanation.—The special rules for a good definition are, 1. It must be adequate, that is, it must agree to all the particular species or individuals included under the same idea. 2. It must be proper, and peculiar to the thing defined. These rules being observed, will render a definition reciprocal with the thing defined, that is, the definition may be used in its place; or they may be mutually affirmed concerning each other. 3. A definition should be clear and plain; no word should be used which has any difficulty in it. 4. A definition should be short, without tautology or superfluous words. 5. Neither the thing defined, nor a synonymous name, should make any part of the definition. See the author's *GRAMMAR OF LOGIC* and *INTELLECTUAL PHILOSOPHY*.

**DEFLAGRATION**, in Chemistry, the act of burning two or more substances together, as charcoal and nitre.

**DEFLECTION**, the turning any thing aside from its former course by some adventitious or external cause. The word is often applied to the tendency of a ship from her true course, by currents, &c. which deflect or turn her out of her right way.

**DEFLECTION** of the *Rays of Light*, is a property which Dr. Hook observed in 1674-5, and read an account of before the Royal Society, March 18, the same year. He says, he found it different from both reflection and refraction; and that it was made towards the surface of the opacous body perpendicularly. This is the same property which Sir Isaac Newton calls inflection. It is called by others diffraction.

**DEFLECTIVE FORCES**, are those forces which act upon a moving body in a direction different from that of its actual course, in consequence of which the body is deflected, or turned, or drawn aside, from the direction in which it is moving. Such is the attractive force of the sun upon the earth in its orbit.

**DEFOLIATION**, in Botany, the fall of the leaves; a term opposed to frondescentia, the annual renovation of the leaves, produced by the unfolding of the buds in spring. Most plants in cold and temperate climates shed their leaves every year; this happens in autumn, and is generally announced by the flowering of the common meadow saffron. The term is only applied to trees and shrubs; for herbs perish down to the root every year, losing stem, leaves, and all.

**DEFORCEMENT**, in Law, the casting any one out of his land, or a withholding of lands and tenements by force from the right owner.

**DEGLUTITION**, in Medicine, the act of swallowing the food, performed by means of the tongue driving the aliment into the oesophagus, which, by the contraction of the sphincter, protrudes the contents downwards.

**DEGRADATION**, in Painting, expresses the lessening the appearance of distant objects in a landscape, in the same manner as they would appear to an eye placed at that distance from them.

**DEGREE**, in Algebra, a term applied to equations, to distinguish the highest power of the unknown quantity. Thus, if the index of that power be 3 or 4, the equation is respectively of the 3d or 4th degree.

**DEGREE**, in Geometry or Trigonometry, is the 360th part of the circumference of any circle. Every circle being considered as divided into 360 parts, called degrees, which are marked by a small ° near the top of the figure, thus, 45° is 45 degrees. The degree is subdivided into 60 smaller parts, called minutes, the minute into 60 others, called seconds; the second into 60 thirds, &c. Thus 45° 12' 20", are 45 degrees, 12 minutes, 20 seconds.

The magnitude or quantity of angles is accounted in degrees; for because of the uniform curvature of a circle in all its parts, equal angles at the centre are subtended by equal arcs, and by similar arcs in peripheries of different diameters; and an angle is said to be of so many degrees as are contained in the arc of any circle comprehended between the legs of the angle, and having

the angular point for its centre. Thus we say, an angle of  $90^\circ$ , or of  $45^\circ 24'$ . It is also usual to say, such a star is elevated so many degrees above the horizon, or declines so many degrees from the equator; or such a town is situated so many degrees of latitude or longitude. A sign of the ecliptic or zodiac contains 30 degrees.

**DEGREE of Latitude**, is the space or distance on the meridian through which an observer must move, to vary his latitude by one degree, or to increase or diminish the distance of a star from the zenith by one degree; and which, on the supposition of the perfect sphericity of the earth, is the 360th part of the meridian. The quantity of a degree of a meridian, or other great circle, on the surface of the earth, is variously determined by different observers, and the methods made use of are also various; and, therefore, without entering into all the histories of this undertaking, we shall present our readers with the following

TABLE of the different Lengths of a Degree, as measured in various Parts of the Earth, the Time of its Measurement, the Latitude of its Middle Point, &c.

| DATE. | LATITUDE.                    | Extent in English Miles & Decimals. | MEASURES.           | COUNTRIES.         |
|-------|------------------------------|-------------------------------------|---------------------|--------------------|
| 1525  | $49^\circ 20\frac{1}{2}'$ N. | 68.763                              | M. Fernel .....     | France.            |
| 1620  | 52 4 N.                      | 66.91                               | Snellius .....      | Holland.           |
| 1635  | 53 15 N.                     | 69.545                              | Norwood .....       | England.           |
| 1644  |                              | 75.066                              | Riccioli .....      | Italy.             |
| 1669  | 49 22 N.                     | 68.945                              | Picard .....        | France.            |

**DEGREE of Longitude**, is the space between two meridians that make an angle of  $1^\circ$  with each other at the poles; the quantity or length of which is variable, according to the latitude, being every where as the cosine of the latitude, viz. as the cosine of one latitude is to the cosine of another, so is the length of a degree in the former latitude to that in the latter, on the supposition that the earth is spherical. But taking the earth as a spheroid, the degree of longitude may be found in any given latitude  $L$ , by saying, 1. As the equatorial diameter is to the polar, so is tang.  $90^\circ - L$ , to tang. of an angle  $A$ ; then, 2. As radius is to sine of  $A$ , so is the length of a degree of the

equator to the length of a degree on the parallel of the given latitude. From these principles is the following Table computed, for expressing the length of a degree of longitude in different latitudes, supposing the earth to possess a perfect sphericity.

**DEGREE, in Universities**, denotes a quality conferred on the students or members thereof, as a testimony of their proficiency in the arts or sciences, and entitling them to certain privileges. The degrees are much the same in all universities, but the laws thereof, and the previous discipline or exercise differ. The degrees are, Bachelor, Master, and Doctor; instead of which last, in some foreign universities, they have Licentiate.

**DEINCLINERS**, in Dialing, are those dials which both decline and incline or recline at the same time.

**DEISTS**, in the modern sense of the word, persons in Christian countries, who, acknowledging all the obligations and duties of natural religion, disbelieve revealed religion. They are so called from their belief in God alone.

**DELEGATES, Court of**, is so called because the judges thereof are delegated by the king's commission under the great seal, to hear and determine appeals in the three following cases: 1. Where a sentence is given in any ecclesiastical cause by the archbishop, or his official. 2. When any sentence is given in any ecclesiastical cause in the places exempt. 3. When a sentence is given in the admiral's court, in suits civil and marine, by order of the civil law. This commission is usually filled with lords spiritual and temporal, judges of the courts at Westminster, and doctors of the civil law.

**DELFT WARE**, a kind of pottery covered with an enamel or white glazing, which gives it the appearance and neatness of porcelain. Some kinds of this enamelled pottery differ much from others, either in their sustaining sudden heat without breaking, or in the beauty and regularity of their forms, of their enamel, and of the painting with which they are ornamented. In general, the fine and beautiful enamelled ware, which approaches the nearest to porcelain in external appearance, is at the same time that which least resists a brisk fire. Again, those which sustain a sudden heat are coarse, and resemble common pottery. This kind of ware has its name from Delft, in Holland, where it is made in large quantities.

**DELIQUESCENCE**, in Chemistry, denotes the property possessed by certain bodies, of attracting moisture from the air, and thereby becoming liquid.

**DELIQUIUM**, in Chemistry, the dissolution or melting of a salt or calx by suspending it in a damp place under ground.

**DEMESNE**, signifies the king's lands, appertaining to him in property. No common person has any domains, simply understood, for we have no land (that of the crown only excepted) which is not holden of a superior, as all depends either mediately or immediately on the crown.

**DEMETRIUS**, a celebrated Cynic philosopher, who lived in the time of the Emperor Vespasian.

**DEMI-CULVERIN**, a piece of ordnance, the least of which is four one-fourth inches bore, 19 feet long, and 2000 lbs. weight. It carries a ball of four inches diameter, and of nine pounds weight, and its level range is 174 paces. A demi-culverin of the largest sort is four three-fourths inches bore, 10 one-third feet long, and weighs 3000 pounds. It carries a ball of four and a half inches diameter, weighing 12 pounds 11 ounces, point-blank 178 paces.

**DEMI-LUNE**, *Half Moon*, in Fortification, an outwork consisting of two faces and two flanks.

**DEMISE**, in Law, is applied to an estate in fee simple, fee tail, or for term of life, and so it is commonly taken in many writs.

**DEMOCRACY**, in Law and polity, denotes a popular government, or that where the supreme power is in the hands of the people. Such for a time were ancient Rome and Athens.

**DEMOCRITUS**, one of the greatest philosophers of antiquity, who flourished about 360 years before the Christian æra.

**DEMOIVRE**, ABRAHAM, an eminent mathematician, was born in France, May 1667, but settled in England at the age of eighteen, where he continued to reside till his death, which happened in November 1754, in the eighty-first year of his age.

**DEMONSTRATION**, a certain or convincing proof of some proposition.

**DEMONSTRATION**, in Logic, a series of syllogisms, all the premises of which are definitions, self-evident truths, or propositions already established.

**DEMURRAGE**, an allowance given to the commander of a trading ship by the merchants, for having detained him longer in port than the time previously appointed for his departure.

**DEMURRER**, a pause or stop put to the proceedings of an action upon a point of difficulty, which must be determined by the court before any farther proceedings can be had therein. He that demurs in law confesses the facts to be true, as stated by the opposite party; but denies that by the law arising upon those facts any injury is done to the plaintiff, or that the defendant has made out a lawful excuse.

**DENARIUS**, in Roman antiquity, the chief silver coin among the Romans, worth in our money about  $7\frac{1}{2}$ d. As a weight, it was the seventh part of a Roman ounce.

**DENDRITES**, or ARBORIZATIONS, an appellation given to figures of vegetables observed in fossil substances, and which are of two kinds, the one superficial, the other internal. The first are chiefly found on the surface of stones, and between the strata and the fissures of those of a calcareous nature. They are mostly brown, changing gradually to reddish yellow. The internal dendrites are of a deep black. The most esteemed sorts are those found in agates, and particularly in the sardonyx, cornelian, and other precious stones brought from the east, and which are commonly denominated Moka stones.

**DENDROMETER**, an instrument invented by Messrs. Duncombe and Whittel, for which they obtained a patent, and so called from its use in measuring trees. It consists of a semi-circle divided into two quadrants, and graduated from the middle; and upon the diameter there hangs a plummet for fixing the instrument in a vertical position. The principal use of it is for measuring the length and diameter of any tree perpendicular or oblique to an horizontal plane, or in any situation of the place on which it rests, or of any figure, whether regular or irregular, and also the length and diameter of the boughs, by mere inspection; and the inventors of it have calculated tables, annexed to their account of the instrument itself, by the help of which the quantity of timber in a tree is obtained without calculation, or the use of the sliding rule. The dendrometer, fitted to a theodolite, may be applied to measuring the heights and distances of objects, accessible or inaccessible, whether situated in planes parallel or oblique to the plane in which the instrument is placed. It may be also used for taking all angles, whether vertical, horizontal, or oblique, in any position of the planes in which they are formed.

**DENEB**, an Arabic term signifying *tail*, and hence applied to the names of certain stars in the tails of some of the constellations, as Deneb Adige in the tail of the Swan.

**DENIZEN**. A denizen is an alien born, who has obtained letters patent whereby he is constituted an English subject. A denizen is in a middle state between an alien and a natural

born or naturalized subject, partaking of the nature of both. He may take lands by purchase, or derive a title by descent through his parents or any ancestor, though they be aliens.

**DENOMINATOR OF A FRACTION**, is that number written below the line, expressing the number of parts into which the

unit is supposed to be divided; thus, in the fractions  $\frac{5}{12}, \frac{a}{b}$ ; 12 and  $b$  are the denominators.

**DENSITY**, strictly speaking, denotes vicinity or closeness of particles; but in mechanical science it is used as a term of comparison, expressing the proportion of the number of equal molecule, or the quantity of matter in one body to the number of equal molecule in the same bulk of another body; density, therefore, is directly as the quantity of matter, and inversely as the magnitude of the body. Since it may be shewn experimentally, that the quantities of matter, or the masses in different bodies, are proportional to their weight, of consequence, the density of any body is directly as its weight, and inversely as its magnitude; or the inverse ratio of the magnitudes of two bodies, having experimentally equal weight (in the same place,) constitutes the ratio of their densities. No body is absolutely or perfectly full of matter, so as to have no vacuity or interstices; on the contrary, it is the opinion of Newton, that even the densest bodies, as gold, &c. contain but a small portion of matter, and a great portion of vacuity, or that they contain a great deal more pores or empty space than real substance. See IMPENETRABILITY.

**DENSITY of the Earth**. The determination of the density of the earth, as compared with that of water, or any other known body, is a subject which has excited considerable interest amongst modern mathematicians, and nothing can at first sight seem more beyond the reach of human science, than the due solution of this problem, yet this has been determined, and on such principles, that if it be not correctly true, it is probably an extremely near approximation. The first idea of determining the density of the earth was suggested by M. Bouguer, in consequence of the attraction of Chimboraco, which affected his plumb-line while engaged with Condamine in measuring a degree of the meridian, near Quito, in Peru. This led to the experiments on the mountain Schellien, in Scotland, which were carried on under the direction of Dr. Maskelyne, and afterwards submitted to calculation by Dr. Hutton, who determined the density of the earth to be to that of water, as  $4\frac{1}{2}$  to 1. But in consequence of the specific gravity of the mountain being assumed rather less than it ought to have been, the above result is less than the true density, as has since been shewn by Dr. Hutton and Professor Playfair, the former of whom makes it, in his corrected paper, as 99 to 20, or nearly as 5 to 1.

The same problem has been attempted on similar principles, but totally in a different manner, by the late Mr. Cavendish, who found the density of the earth to be to that of water, as 5.48 to 1. Taking a mean of all these, we have the density of the earth to that of water, as 5.24 to 1, and which, as we before observed, is probably an extremely near approximation.

**DENSITY of the Planets**. We have seen, in the preceding part of this article, that the density of a body is directly as its mass, and reciprocally as its magnitude; therefore, any two of these being given, the third may be undetermined. Now the magnitude of the several planets, as also of the sun, being supposed known from observation, if we can determine their masses, their densities will thus also become known.

The power of attraction with which any central body acts upon another body revolving about it, is directly as the mass of the central body, and reciprocally as the square of the distance of the revolving body; and this power may be measured by the deflection of the revolving body in a given time from the direction of its tangent. Now, if we consider the earth as the central, and the moon as the revolving body, the deflection of the latter in one second is known to be  $\frac{18}{3600}$  of a foot, that is, it deviates so much from the direction of its tangent in one second of time, as may be readily ascertained by computation, being equal to the versed sine of the arc described in one second. If the distance between the earth and moon had been double what it is, this deflection would have been only  $\frac{1}{4}$  of the above, if the distance were only half what it is, this deflection

would be four times as much, and so on, because the power of the central body is reciprocally as the square of its distance. Again, if the distance of the bodies remain the same, and the mass of the central body be doubled, the deflection will be doubled; if tripled, the deflection will be tripled, and so on; because the power of the central body is directly as its mass. Now Jupiter's first satellite revolves about that planet at the same distance as the moon does about the earth, but its deflection in one second is 256 times that of the moon; whence, the distances being equal, it follows, that the mass of Jupiter is 256 times greater than that of the earth. Had these distances not been equal, we must have found what the deflection of the moon would be at the given distance; then comparing this with that of the satellite, the mass in any other case might be determined. Having thus found the mass, and the magnitude being known, we shall have, assuming the mass of the earth as unity; as 1 divided by the magnitude of the earth, is to the mass of any planet divided by its magnitude; so is 1, the density of the earth, to the density of the planet; and in this way the density of any planet having a satellite, may be readily computed. In other cases, recourse must be had to the disturbing force, which is of a very laborious computation. The density of the sun, and the several planets, as deduced from Laplace's "System du Monde," is as follows: *viz.*

|               |         |                |         |
|---------------|---------|----------------|---------|
| Sun,.....     | 0.25226 | Mars, .....    | 0.65630 |
| Mercury,..... | 2.58330 | Jupiter, ..... | 0.20093 |
| Venus,.....   | 1.02400 | Saturn, .....  | 0.10349 |
| Earth,.....   | 1.00000 | Uranus, .....  | 0.21085 |

**DENTIFRICE**, a remedy for the teeth, of which there are various kinds; generally, however, they are made of earthy substances mixed with alum. Those formed of acids are very pernicious.

**DEODAND**, in Law, is a forfeiture of that thing or animal which occasions the death of a human being by mischance. Where the death is purely accidental, and no blame attached to any person, the coroner's jury usually find a deodand of one shilling.

**DEPARTURE**, in Navigation, is the easting or westing of a ship in respect of the meridian it departed or sailed from; or it is the difference of longitude in miles either east or west, between the present meridian the ship is under, and that where the last reckoning or observation was made.

**DEPOT**, any place in which military stores are deposited. Also a particular place at the tail of the trenches, out of the reach of the cannon, where the troops generally assemble who are ordered to attack the outworks.

**DEPRESSION OF EQUATIONS**, in Algebra, is the reduction of an equation to one of lower dimensions, an operation, however, that can only be effected in particular cases, *viz.* when a certain relation has place between the roots of the equation; thus if an equation has equal roots with either like or contrary signs, or if the equation be a reciprocal one, having each pair of roots the reciprocal of each other, and in short under almost any known relation of the roots the equation may be depressed to one of lower dimensions. If an equation have two equal roots it may be depressed one degree; if three equal roots, it may be depressed two degrees, and so on; and in reciprocal equations of even dimensions, may be depressed to half the original degree; and if they are of odd dimensions, to half the original degree minus 1.

**DEPRESSION OF THE POLE**. When a person sails or travels towards the equator he is said to depress the pole; because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This arises from the spherical figure of the earth. When a star is under the horizon it is termed the depression of that star under the horizon. The altitude or depression of a star is an arch of the vertical circle, or azimuth, intercepted between the horizon and the star.

**DEPRESSION, or Dip of the Visible Horizon**, denotes its sinking or dipping below the true horizontal plane, by the observer's eye being raised above the surface of the sea; in consequence of which the observed altitude of an object is by so much too great. The following table shews the depression or dip at the horizon of the sea for different heights of the eye.

TABLE.

| Height of the eye. | Dip of the horizon. | Height of the eye. | Dip of the horizon. | Height of the eye. | Dip of the horizon. |
|--------------------|---------------------|--------------------|---------------------|--------------------|---------------------|
| Feet.              | ' "                 | Feet.              | ' "                 | Feet.              | ' "                 |
| 1                  | 0 57                | 13                 | 3 26                | 26                 | 4 52                |
| 2                  | 1 21                | 14                 | 3 34                | 28                 | 5 3                 |
| 3                  | 1 39                | 15                 | 3 42                | 30                 | 5 14                |
| 4                  | 1 55                | 16                 | 3 49                | 35                 | 5 39                |
| 5                  | 2 8                 | 17                 | 3 56                | 40                 | 6 2                 |
| 6                  | 2 20                | 18                 | 4 3                 | 45                 | 6 24                |
| 7                  | 2 31                | 19                 | 4 10                | 50                 | 6 44                |
| 8                  | 2 42                | 20                 | 4 16                | 60                 | 7 23                |
| 9                  | 2 52                | 21                 | 4 22                | 70                 | 7 59                |
| 10                 | 3 1                 | 22                 | 4 28                | 80                 | 8 32                |
| 11                 | 3 10                | 23                 | 4 34                | 90                 | 9 3                 |
| 12                 | 3 18                | 24                 | 4 40                | 100                | 9 33                |

**DERHAM, JOHN**, an eminent philosopher and mathematician, born at Worcester in 1657, was the author of many valuable articles in the "Philosophical Transactions," &c. Derham died in 1738, at Upminster.

**DERVIS**, a name given to all Mohammedan monks, though of various orders. They have convents in the same manner as the monks in the Catholic and Greek churches.

**DESAGULIERS, JOHN THEO.** an eminent experimental philosopher, was born at Rochelle, in France, in 1683, but educated in England, where he afterwards continued to reside. He was a member of several learned societies, and made numerous communications on the subjects of *optics, mechanics, &c.* both to the Royal Society of London, and to the Academy of Sciences at Paris.

**DESCENSION, RIGHT**, the arc of the equator which descends with the sign or star below the horizon of a direct sphere; and *oblique Descension* is the arc of the equator that descends with the sun or star in an oblique sphere.

**DESCENT OF BODIES**, in Mechanics, is their motion or tendency towards the centre of the earth, either in a direct or oblique direction. The laws of the descent of bodies in free space are given in the article **ACCELERATION**, their descent along inclined planes in the article **INCLINED PLANE**, and in fluids under **RESISTANCE**. We shall, therefore, merely refer to a singular phenomenon respecting falling bodies, which is their deviation from the perpendicular, occasioned by the rotation of the earth on its axis. When the idea of the earth's motion was started by Copernicus, it was strongly objected to it, that if the earth really revolved, a stone let fall from the top of a tower ought to fall considerably to the westward of the foot of it, being, according to their notion, left behind by the motion of the earth; and the supporters of the doctrine were not then sufficiently acquainted with the composition of motion to explain away the difficulty. However, when the laws of motion became better understood, it was discovered, that the body, instead of falling to the westward of the tower, ought to fall a little to the eastward of it, in consequence of the velocity of rotation being greater at the top than at the foot of the tower; and this deviation is said to have been really detected by M. Guglielmini and M. Benzenberg, the former finding it to be equal to 8 lines in falling 241 feet, and the latter 5 lines for a fall of 262 feet. But how far experiments on such delicate subjects may be depended on, may be a matter of doubt, but of the truth of the theoretical deflection no doubt can be entertained.

**DESCENT**, in Heraldry, expresses the coming down of any thing from above; as, a lion *en descent* with his head towards the base points and his heels towards one of the corners of the chief, as if he were leaping down from some high place.

**DESCENT, Line of Swiftest**, is that which a body, falling by the action of gravity, describes, in the shortest time possible, from one given point to another. And this line is the arc of a cycloid, when the one point is not perpendicularly over the other.

**DESCENT**, in Law, is the title by which a man, on the death of his ancestor, acquires his estate by right of representation

as his heir at law; and an estate so descending to the heir is in law called the inheritance.

**DESIDERATUM**, the desirable accomplishment of some advancement in art or science; as, the use of pendulums where there are irregular motions.

**DESIGN**, in Painting, the first idea of a large work drawn roughly, and on a small scale, with the intention of being executed and finished in large. *See* **DRAWING**. In Music, design means both the invention and execution of the subject, in all its parts, and agreeably to the general order of the whole. In Manufactures, design expresses the figures with which the workman enriches his stuff or silk, and which he copies after his own drawing or the sketches of some artist. In Building, the term *ichnography* may be used, when by design is only meant the plan of a building, or a flat figure drawn on paper; when some side or face of the building is raised from the ground, we may use the term *orthography*: and when both front and sides are seen in perspective, it may be termed *scenography*.

**DESCRIBENT**, in Geometry, is the line or surface, from the motion of which, a surface, or body, is supposed to be generated or described.

**DESCRIPTIVE GEOMETRY**, the name given to a species of geometry almost entirely new, and which we owe in great measure to M. Monge. When any surface whatever penetrates another, there most frequently result from their intersection curves of double curvature, the determination of which is necessary in many arts, as in groined vault-work, cutting arch-stones, wood-cutting, for ornamental work, &c. the form of which is frequently very singular and complicated: it is in the solution of problems appertaining to these subjects that descriptive geometry is especially useful.\*

**DETACHED PIECES**, in Fortification, are outworks at a distance from the body of the place; as demilunes, ravelines, bastions, &c. In Painting, the figures are well detached, when they stand free and disengaged from each other.

**DETACHMENT**, in Military affairs, a number of soldiers drawn out from regiments or companies equally, to be employed as the general thinks proper; whether on an attack, at a siege, or in parties to scour the country.

**DETERMINATE PROBLEM**, in Geometry, that which has a limited number of answers: as the following, *viz.* To describe an isosceles triangle on a given line, whose angles at the base shall be double that at the vertex.

**DETINUE**, in Law, a writ which lies where any man comes to goods or chattels either by delivery or by finding, and refuses to give them up; and it lies for the detaining, when the detaining was unlawful.

**DETONATION**, in Chemistry, the noise and explosion which any substance makes upon the application of fire. It is also called *fulmination*. Hence the detonating balls, detonating powder.

**DEVELOPMENT**, a term in frequent use among modern algebraists, to denote the transformation of any fraction into the form of a series.

**DEVELOPMENT OF A SPHERIC SURFACE ON A PLANE**, is applied to the drawing of a small portion of the earth's surface in a manner nearly spherical, by supposing the sphere circumscribed by a polyhedron, the side of which is extended upon a plane. In approximating the development of the spheric surface, there are two methods of considering the subject: one, by supposing the polyhedrous surface to consist of conic frustums, each touching the surface of the sphere in the middle; the other, by supposing the polyhedrous surface comprised of frustums of a cylinder, meeting each other in planes passing through the centre of the sphere, and intersecting each other in one common diameter as an axis; and because both the conic and cylindric surfaces are developable, the surface of the circumscribing polyhedron will also be developable, and therefore will admit of being correctly represented. Now, supposing all the sides of the figure to be equal, and increased in number at pleasure, the greater the number, the nearer will the surface of the polyhedron coincide with that of the sphere; and consequently, any portion of the developed surface of the polyhedron, will be very nearly equal and similar to the corresponding portion of the spheric surface. Each of these

different methods of representing the spheric surface has its peculiar advantage and disadvantage, when applied to the art of map-making: the conic method of development is best adapted to represent countries to any extent in the difference of longitude, or round the whole circumference of the earth if required, to a certain extent in difference of latitude; and the cylindric method of development is well adapted to represent countries contained between any two parallels of latitude, but not to have any considerable difference of longitude. Of these two different projections by development, the conical projection is the most simple, and is attended with the least trouble, on account of the facility of describing the parallels of latitude in concentric circles, and the meridians in straight lines. In comparing a spherical zone to a truncated cone, in order to construct its development, we view the parallels as circles described from the summit of the cone taken as a common centre; and the meridians are right lines subjected to pass through that point. It is visible that the result will approach the nearer, in proportion as the map shall embrace less extent in latitude. This projection may vary in different ways; for it may be supposed that the cone is a tangent to the middle parallel of the map, and in consequence, exterior; or, that it may be in part inscribed in the sphere, that is to say, formed by the secants of the meridians. In the first case, the map will not be perfectly exact, except on the middle parallel, which will preserve in its development the length which it really possesses on the sphere; but the parallels placed above and beneath, will exceed those on the sphere, which are correspondent.

With respect to the application of the development of the conic surface in the construction of maps, the Rev. Patrick Murdoch proposed to substitute to the tangent cone, a cone partly inscribed and determined upon this condition, *that the part of the area comprehended in the map, should be equivalent to that of the spherical zone which it represents.\** Though it may be difficult, at first sight, to conceive that the surface of the globe can be represented by a part of the surface of a cone, yet this is the case in regard to D'Anville's map of Russia. You may easily form the surface of a cone, of any plain piece of paper cut into a circular form or base; and you will as easily consider, that if a cone about twice the height of the semi-diameter of the globe, were to be conceived as standing on the same base with the hemisphere, namely, on the equator, the surface of such a cone would in part lie within the surface of the globe; and then, nothing can be more natural, than to suppose that the surface of the globe at so small a distance from the surface of the cone, might be very easily projected or delineated on it; and in such a case, the projection of the countries and their bearings, distances, &c. will be very nearly the same on the surface of the included part of the cone, as on that of the globe itself; and when such a geographical conical surface is cut out and expanded, it makes the map now under consideration.

When any portion of the earth's surface is projected on a plane, or transferred to it by whatever method of description, the real dimensions, and often the figure and position of countries, are much altered and misrepresented. The particular methods of description used among geographers are so various, that we might suspect them to be faulty; but in most of their works we find these two blemishes, the linear dimensions visibly false, and the intersections of the circles oblique; so that a quadrilateral space shall often be represented by an oblique-angled rhomboid figure, whose diagonals are very far from equal; and yet, by a strange contradiction, you shall see a scale of distances inserted in such a map. The last of these blemishes is removed, and the other lessened, in some maps of P. Schenk's of Amsterdam, a "map of the Russian empire," the "*Germania Critica*" of the famous Professor Meyer, and a few more. In these the meridians are straight lines, converging to a point, from which, as a centre, the parallels of latitude are described, and I have given a rule for drawing such maps, under the article **MAPS**.

\* See the Editor's Treatise on the Construction of Maps, for this development, p. 113, &c.

**DEVISE**, or **DEVICE**, in Heraldry, Painting, and Sculpture, any emblem used to represent a certain family, person, action, or quality, with a suitable motto applied in a figurative sense.

**DEVISE**, in Law, the act whereby a person bequeaths his lands or tenements to another, by his last will and testament. The person who makes this act, is called the devisor, and he in whose favour the act is made, is termed the devisee.

**DEW**, that condensation of vapour which we perceive on the grass of the fields, &c. and which is produced by the evaporation of moisture from the earth, both before and after sunset. Under certain circumstances, the air holds not the same quantity of water in solution, and the result is a deposition of it in aqueous particles; during day, and under the effects of electricity, definite and floating clouds are the result, and the processes of rain often commence; but in fine weather, in the evening, the vapour plane being destroyed, the vapour so deposited precipitates down in dew. During the heat of the day a great quantity of vapour is thrown into the atmosphere from the surface of the earth and waters. When the evening returns, if the vapour has not been carried off in part by currents, it will often happen that more remains diffused in the general atmosphere than the temperature of the night will permit to subsist under the full pressure of the aqueous atmosphere. A decomposition of the latter then commences, and is continued until the general temperature and aqueous pressure arrive at an equilibrium, or until the returning sun puts an end to the process. Dew appears only on calm and clear nights: very little is ever deposited in opposite circumstances, and little only when the clouds are very high. It is never seen on nights both cloudy and windy; and if in the course of the night the weather, from being serene, should become dark and stormy, dew which had been deposited will disappear. In calm weather, if the sky be partially covered with clouds, more dew will appear than if it were entirely uncovered.

**DIABETES**, in Physic, an excessive discharge of urine, which comes away crude, and exceeds the quantity of liquids drank.

**DIACAUSTIC CURVE**, a species of the caustic curves formed by refraction.

**DIACOUSTICS**, or **DIAPHONICS**, the consideration of the properties of sound refracted in passing through different mediums.

**DIÆRESIS**, in Grammar, the division of one syllable into two, which is usually noted by two points over a letter, as aulāi instead of aulæ, dissoliūenda for dissolvenda.

**DIAGNOSTIC**, in Medicine, a term given to those signs which indicate the present state of a disease, its nature and cause.

**DIAGONAL**, in Geometry, a right line drawn across a quadrilateral or other figure, whether plane or solid, from the vertex or summit of one angle to that of another; and is by some authors called the diameter, and by others the diametral of the figure. It is demonstrable, 1. That every diagonal divides a parallelogram into two equal parts. 2. That two diagonals drawn in any parallelogram bisect each other. 3. A line passing through the middle point of the diagonal of a parallelogram, divides the figure into two equal parts. 4. The diagonal of a square is incommensurable with one of its sides. 5. The sum of the squares of the two diagonals of every parallelogram is equal to the sum of the squares of the four sides. 6. In any trapezium, the sum of the squares of the four sides is equal to the sum of the squares of the two diagonals, together with four times the square of the distance between the middle points of the diagonals. 7. In any trapezium, the sum of the squares of the two diagonals is double the sum of the squares of two lines bisecting the two pairs of opposite sides. 8. In any quadrilateral inscribed in a circle, the rectangle of the two diagonals is equal to the sum of the two rectangles under the two pairs of opposite sides. 9. In every parallelopiped the sum of the squares of the four diagonals of the solid, is equal to the sum of the squares of its twelve edges. 10. In every hexædron, regular or not, the sum of the squares of the twelve edges, plus the sum of the squares of the twelve diagonals of the faces, is equal to three times the sum of the squares of the four diagonals which cross the solid, plus four times the sum of the squares of the six right lines which join, two by two, the mid-

dle points of those four latter diagonals. 11. In every polygon, and in every polyëdron, the sum of the squares of the lines which join, two by two, the middle points both of sides and diagonals, is the quarter of the sum of the squares of those sides and diagonals; multiplied by the number of summits of the polygon or polyëdron, diminished by two units. 12. A farther generalization of the latter property leads to the most celebrated property of the centre of gravity.

**DIAGRAM**, is a scheme for explanation or demonstration of any figure, or of its properties.

**DIAL**, or **SUN-DIAL**, an instrument serving to measure time, by means of the shadow of the sun. The word is formed from *dies*, day, because indicating the hour of the day. The ancients also call it *sciathericum*, from its doing it by the shadow.

**DIAL** is more accurately defined, a draught, or description, of certain lines on a plane, or surface of a body given, so contrived as that the shadow of a stile, or ray of the sun, passed through a hole therein, shall touch certain points at certain hours. The antiquity of dials is beyond doubt. Some attribute their invention to Anaximenes Milesius, and others to Thales. Vitruvius mentions one made by the ancient Chaldee historian Berosus, on a reclining plane, almost parallel to the equinoctial. Aristarchus Samius invented the hemispherical dial. And there were some spherical ones, with a needle for a gnomon. The discus of Aristarchus was an horizontal dial, with its limb raised up all round, to prevent the shadows stretching too far. It was late ere the Romans became acquainted with dials. The first was set up by Papirius Cursor, at or near the temple of Quirinus; but being inaccurate about 30 years after, another was brought out of Sicily by the consul M. Valerius Messala, which he placed on a pillar near the Rostrum; but neither did this shew time truly, because not made for that latitude; and after using it 99 years, Martius Philippus set up another more exact.

The diversity of sun-dials arises from the different situation of the planes, and from the different figure of the surfaces upon which they are described; whence they become denominated *equinoctial*, *horizontal*, *vertical*, *polar*, *direct*, *erect*, *declining*, *inclining*, *reclining*, &c.

**Universal Dial**. There are several kinds of dials called universal, because they serve for all latitudes. One of a very ingenious construction has lately been invented by Mr. G. Wright, of London. The hour circle, or arch E, and latitude arch C, are the portions of two meridian circles; one fixed, and the other moveable. The hour or dial-plate *SEI* at the top, is fixed to the arch C, and has an index that moves with the hour circle E; therefore the construction of this dial is perfectly similar to the construction of the meridians and hour-circles upon a common globe. The peculiar problems to be performed by this instrument are, 1. To find the latitude of any place. 2. The latitude of the place being known, to find the time by the sun and stars. 3. To find the sun or stars altitude and azimuth.

But the dial being properly adjusted, a great variety of astronomical and trigonometrical problems may be wrought upon it, which, however, our limits will not allow of detailing; we must therefore refer

the reader to Jones's "Instrumental Dialing," where he will find ample information on this subject.

**DIALING**, the art of drawing dials on the surface of any given body, whether plane or curved. Dialing is wholly founded on the first motion of the heavenly bodies, and chiefly the sun; or rather on the diurnal motion of the earth; so that the elements of spherics, and spherical trigonometry, should be understood before a person advances to the theory of dialing. The edge of the plane by which the time of the day is found, is called the stile of the dial, which must be parallel to the earth's axis; and the line on which this plane is erected, is called the

Universal Dial.

substile. The angle included between the substile and stile, is called the elevation or height of the stile, as in the next figure.

The principles of dialing may be aptly illustrated by the phenomena of a hollow or transparent sphere, as of glass. Thus suppose a  $P B p$  to represent the earth as transparent; and its equator as divided into 24 equal parts by so many meridian semicircles  $a, b, c, d, e$ , &c. one of which is the geographical meridian of any given place, as London, which it is supposed is at the point  $a$ ; and if the hour of 12 were marked at the equator, both upon that meridian and the opposite one, and all the rest of the hours in order on the other meridians, those meridians would be the hour circles of London; because, as the sun appears to move round the earth, which is in the centre of the visible heavens, in 24 hours, he will pass from one meridian to another in an hour. Then, if the sphere had an opaque axis, as  $P E p$ , terminating in the poles  $P$  and  $p$ , the shadow of the axis, which is in the same plane with the sun, and with each meridian, would fall upon every particular meridian and hour, when the sun came to the plane of the opposite meridian; and would consequently shew the time at London, and at all other places on the same meridian. If this sphere were cut through the middle by a solid plane  $A B C D$  in the rational horizon of London, one half of the axis  $E P$  would be above the plane, and the other half below it; and if straight lines were drawn from the centre of the plane to those points where its circumference is cut by the hour circles of the sphere, those lines would be the hour lines of an horizontal dial for London; for the shadow of the axis would fall upon each particular hour line of the dial, when it fell upon the like hour circle of the sphere, as in the annexed figure.

If the plane which cuts the sphere be upright, as  $A F C G$ , touching the given place, for example, London at  $F$ , and directly facing the meridian of London, it will then become the plane of an erect direct south dial; and if right lines be drawn from its centre  $E$ , to those points of its circumference where the hour circles of the sphere cut it, these will be the hour lines of a vertical or direct south dial for London, to which the hours are to be set in the figure, contrary to those on an horizontal dial; and the lower half  $E p$  of the axis will cast a shadow on the hour of the day in this dial, at the same time that it would fall upon the like hour circle of the sphere, if the dial plane was not in the way.

If the plane still facing the meridian, be made to incline or recline, any number of degrees, the hour circles of the sphere will still cut the edge of the plane in those points to which the hour lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on these lines at the respective hour. The like will still hold, if the plane be made to decline by any number of degrees from the meridian towards the east or west, provided the declination be less than 90 degrees, or the reclination be less than the co-latitude of the place, and the axis of the sphere will be the gnomon; otherwise, the axis will have no elevation above the plane of the dial, and cannot be a gnomon.

Thus it appears that the plane of every dial represents the plane of some great circle on the earth, and the gnomon of the earth's axis; the vertex of a right gnomon, the centre of the earth or visible heavens; and the plane of the dial is just as far from this centre as from the vertex of this stile. The earth itself, compared with its distance from the sun, is considered as a point; and, therefore, if a small sphere of glass be placed

upon any part of the earth's surface, so that its axis be parallel to the axis of the earth, and the sphere have such lines upon it, and such planes within it, as above described; it will shew the hours of the day as truly as if it were placed at the earth's centre, and the shell of the earth were as transparent as glass.

To describe an Horizontal Dial, geometrically, as in the annexed figure.—Draw a meridian line  $K L$ , (see MERIDIAN Line,) and from any part  $C$ , erect the perpendicular  $C D$ , and make the angle  $C A D$  = to the latitude of the place, and draw the line  $d E$ , meeting within  $E$ . Make  $E B$  =  $C D$ , and from the centre  $B$ , with radius  $E B$ , describe a quadrant  $E B F$ , which divide into six equal parts. Through  $E$  draw  $E h$  perpendicular to  $A B$ . From the centre  $B$  through the several subdivisions of the quadrant  $E F$ , draw the lines  $B a, B b$ , &c. meeting the line  $d h$  in the points  $a, b, c$ , &c.

From  $E$  draw the line  $E h$ , and set off  $E e, E f, E g$ , &c. respective equal to  $E a, E b, E c$ , &c. Through the point  $A$  draw the lines  $a X I, b X, c X$ , &c. also  $e I, f I I, g I I I$ , &c. which will be the several hour lines required. Then at  $A$  erect the gnomon or stile at an angle equal to the elevation of the pole, or latitude of the place, and the dial will be complete.

To compute the Angles of the Hour Lines, trigonometrically.

As Radius

Is to the sine of the latitude of the place,

So is tangent of sun's distance from the meridian,

To the tangent of the angle from the meridian on the dial.

The preceding construction and computation for the case of a horizontal dial, may be said to include the whole theory of dialing; for there is no plane, however obliquely situated with respect to any given place, but what is parallel to the horizon of some other place, and therefore, if we find that other place by a problem on the terrestrial globe, or by a trigonometrical calculation, and construct a horizontal dial for it, that dial applied to the plane where it is to serve, will be a true dial for that place.—Thus, an erect direct south dial in  $51\frac{1}{2}^\circ$  north latitude, would be a horizontal dial on the same meridian,  $90^\circ$  southward, which falls in with  $38\frac{1}{2}^\circ$  south latitude; but if the upright plane declines from facing the south at the given place, it would be a horizontal plane  $90^\circ$  from that place; but for a different longitude, which would alter the reckoning of the hours accordingly.

A TABLE of the Angles which the Hour-Lines form with the Meridian on a Horizontal Dial for every half Degree of Latitude, from  $50^\circ$  to  $59^\circ 30'$ .

| 58        | 12 48           | 26 5            | 40 18             | 55 45              | 72 27            | 90 00            |
| 58 30     | 12 52           | 26 13           | 40 27             | 55 54              | 72 33            | 90 00            |
| 59        | 12 56           | 26 20           | 40 36             | 56 2               | 72 39            | 90 00            |
| 59 30     | 13 0            | 26 27           | 40 45             | 56 10              | 72 44            | 90 00            |

In this table, the angles formed by the lines for V in the morning and VII in the evening, IV in the morning and VIII in the evening, &c. are not marked, because they are the same as those for VII in the morning and V in the evening, VIII in the morning and IV in the evening, only they lie on opposite sides of the VI o'clock hour-lines, as was shewn in the construction of the horizontal dial.

The use of the table may be easily comprehended: if the place for which a horizontal dial is to be made, corresponds with any latitude in the table, the angles which the hour-lines make with the meridian may be seen at once. For example, it appears that the hour lines of XI and I must, in the latitude of  $56^{\circ}$ , make angles of  $12^{\circ} 32'$  with the meridian. If the latitude be not contained in the table, proportional parts may be taken without any sensible error. Thus, if the latitude be  $54^{\circ} 15'$ , and the angles made by the hour-lines of XI or I be required, as it appears from the table that the increase of  $30'$  in the latitude, viz. from  $54^{\circ}$  to  $54^{\circ} 30'$ , corresponds to an increase of  $4'$  in the hour angle at the centre of the dial, we may infer, that an increase of  $15'$  will require an increase of  $2'$  nearly, and therefore that the angle required will be  $12^{\circ} 16'$ .

**DIALING-GLOBE**, an instrument of brass or wood, with a plane fitted to the horizon, and an index so contrived as to give a clear illustration of the scientific principles on which dials are constructed.

**DIALING-LINES**, or **SCALES**, are graduated lines placed on rulers, or the edges of quadrants and other instruments, for the construction of dials. These are, 1. A scale of six hours, which is a double tangent, or two lines of tangents, each of  $45^{\circ}$ , set together in the middle, and equal to the line of sines, with the declination set against the meridian altitudes in the latitude of the place. 2. A line of latitudes, fitted to the hour-scale, and made by this canon: As the radius; the chord of  $90^{\circ}$  :: the tangents of each respective degree of the line of latitudes : tangents of other arcs. And then the natural sides of these arches are the numbers, which taken from a diagonal scale of equal parts, shall graduate the divisions of the line of latitudes to any radius. The lines of hours and latitudes are general, for pricking down all dials with centres. The other scales are particular, and give the several requisites for upright declining dials by inspection. They are, 1. A line of chords. 2. A line for the substile's distance from the meridian. 3. A line for the stile's height. 4. A line of the angle of 12 and 6. 5. A line of inclination of meridians.

**DIALING-SPHERE**, an instrument made of brass, with several semicircles sliding over each other on a moveable horizon, to demonstrate the nature of spherical triangles, and to give the true idea of drawing dials.

**DIAMETER**, in Geometry, the line which, passing through the centre of a circle, or other curvilinear figure, divides it, or its respective ordinates, into equal parts.

*Conjugate DIAMETER* of a *Conic Section*, is a line drawn through the centre of the figure to its sides, and the shortest of the two diameters of the figure.

*Transverse DIAMETER* of a *Conic Section*, is a line drawn through the foci to the curve.

*How to find the DIAMETER of Shot or Shells.*—For an iron ball, whose diameter is given, supposing a nine-pounder, which is nearly four inches, say the cube root 2.08, (of nine pounds,) is to four inches, as the cube root of the given weight, is to the diameter sought. Or, if 4 be divided by 2.08, the cube root of 9, the quotient 1.923 will be the diameter of one-pound shot, which being continually multiplied by the cube root of the given weight, gives the diameter required. Or by logarithms thus: If the logarithm of 1.923, which is 2.83979, be constantly added to the third part of the logarithm of the weight, the sum will be that of the diameter. Suppose a shot to weigh 24 lbs. add the given logarithm 2.83979 to .460070, the third part of the logarithm 1.3802112 of 24, the sum .7440494 will be the logarithm of the diameter of a shot weighing 24 pounds, which is 5.5468 inches. If the weight should be expressed by a fraction, the rule is the same; for instance, the diameter of a pound and a half ball, or three seconds, is found by adding the logarithm .2839793 found above, to .0586971, one-third of the logarithm of two-thirds; the sum .3426764 will be the logarithm of the diameter required. *i. e.* 2.2013 inches.

**DIAMETER** of the *Planets*, &c. in Astronomy, are either real or apparent. The real diameters are the absolute measure of them in miles, &c. and their apparent diameters are the angles under which they appear to spectators on the earth, and are therefore different under different circumstances; viz. according as they are nearer or more remote from the earth. As these angles are very small, the diameter of the planet may be considered as part of a circle of which the earth is the centre, and they are said to contain so many minutes, seconds, &c. as is measured by that arc, and consequently the apparent diameter of a planet is in the inverse ratio of its distance. And hence again, the apparent diameters and distances being known, their real diameters thence become determined.

TABLE of the Mean and Apparent Diameters of the Planets.

|            | Apparent mean diameter, as seen from the earth. | Apparent diameter, as seen from the sun. | Mean diameter in English miles. | Apparent diameter of the sun, seen from the planets. | Proportional diameter. |

**DIAMOND**, *see* CHEMISTRY, for the properties of the diamond. There are various kinds of diamonds, as the Cornish, Rose Arran, &c. but these are inferior to the diamonds of Brazil; and these last to the gems of India. Diamond, in the glass trade, is an instrument used for cutting glass, in which is set, in lead or silver, a crystal or gem that will cut glass.

**DIAMOND**, in Heraldry, expresses the black colour in the achievements of peerage.

**DIAMOND Mines** are found in Brazil, in South America; and in Golconda, Visapour, Bengal, and the island of Borneo. The diamond can only be cut and ground by itself and its own substance. To bring it to that perfection which augments its price so considerably, they begin by rubbing several against each other while rough, after having first glued them to the ends of two wooden blocks, thick enough to be held in the hand. It is this powder thus rubbed off the stones, and received in a little box for the purpose, that serves to grind and polish the stones. Diamonds are cut and polished by a mill, which turns a wheel of soft iron sprinkled over with diamond dust mixed with oil of olives. The same dust, well ground and diluted with water and vinegar, is used in the sawing of diamonds, which is performed with an iron or brass wire, as fine as a hair. Sometimes, in lieu of sawing the diamonds, they clean them, especially if there are any large shivers in them.

The first water, in diamonds, means the greatest purity and perfection of their complexion, which ought to be that of the purest water. When diamonds fall short of this perfection, they are said to be of the second or third water, &c. till the stone may be properly called a coloured one; for it would be an impropriety to speak of an imperfectly-coloured diamond, or one that has other defects, as a stone of a bad water only.

For the valuation of diamonds of all weights, the following rule has been given. First, suppose the value of a rough diamond to be settled at £2 per carat at a medium, then to find the value of diamonds of greater weights, multiply the square of their weight by 2, and the product is the value required: *e.g.* To find the value of a rough diamond of two carats;  $2 \times 2 = 4$ , the square of the weight, which multiplied by 2, gives £8, the true value of a rough diamond of two carats. For finding the value of manufactured diamonds, we suppose half their weight to be lost in manufacturing them; and therefore, to find their value, we must multiply the square of double their weight by 2, which will give their true value in pounds. Thus, to find the value of a wrought diamond weighing two carats; we first find the square of double the weight,

viz.  $4 \times 4 = 16$ ; then  $16 \times 2 = 32$ . So that the true value of a wrought diamond of two carats is £32. On these principles Jeffries has constructed tables of the price of diamonds from 1 to 100 carats. The value of diamonds, however, depends so much on imagination, and not on real use, that no positive rule can be given. In the very large diamonds, Jeffries's rule will be far from the truth.—Diamond chemically analyzed, is found to consist of pure carbon, that is, charcoal.

**DIAMOND**, *Brilliant*, is that which is cut in faces at the top and bottom; and whose table, or principal face at top, is flat.

**DIAMOND**, *Rose*, is one that is quite flat underneath, with its upper part cut in many little faces, usually triangles, the uppermost of which terminates in a point.

**DIANÆ ARBOR**, or **ARBOR LUNÆ**, in Chemistry, the beautiful crystallizations of silver, dissolved in nitrous acid, to which some quicksilver is added; and so called from their resembling the trunk, branches, leaves, &c. of a tree.—(See page 53, col. 2.)

**DIANTHUS**, a genus of plants belonging to the class diandria, or hermaphrodite plants, as the clove gillflower, carnation, pink, sweet-william, &c.

**DIAPASON**, in Music, an interval that expresses the *octave* of the Greeks, or a rule or scale whereby musical instrument makers adjust the pipes of organs, and cut the holes of hautboys, flutes, &c. in due proportion, for performing the tones, semitones, and concords, with precision.

**DIAPHRAGM**, in Anatomy, the midriff, a strong muscular substance that separates the breast and thorax from the abdomen, and thus portions off the abdominal and thoracic viscera.

**DIARRHŒA**, or **LOOSENESS**, in Medicine, is a frequent and copious evacuation of liquid excrement by stool.

**DIARY**, a journal or day-book, containing an account of every day's proceedings.

**DIASTOLE**, in Physic, signifies the dilatation of the heart, auricles, and arteries; and stands opposed to the systole, or contraction of the same parts.

**DIATESSARON**, in Music, applied by the Greeks to that interval which we call a fourth; consisting of a greater tone, a lesser tone, and one greater semitone. The word is also used for the four gospels, arranged after the manner of a harmony.

**DIBBLING**, in Agriculture, a mode of setting corn, or other seeds, practised with advantage in places where labour is cheap; it is chiefly used for putting wheat crops into the ground. The practice of dibbling was first introduced into Norfolk, about twenty-five years ago. The method of dibbling is this: when the land is ploughed and rolled, a man with an iron dibble, of about three feet long, in each hand, walking backwards, makes two rows of holes in each furrow, at about four inches' distance from each other, and an inch or two deep. The dibbler is followed by two or three women, or children, who drop two or three grains into each hole. The field is afterwards bush-harrowed. The usual quantity of seed is from a bushel and a half to two bushels per acre, and the expense of labour about ten shillings. An experienced dibbler, with three active attendants, will plant half an acre a day, making six holes in every foot length.

**DICE**, among gamblers, certain cubical pieces of bone or ivory, marked with dots on each of their faces, from one to six, according to the number of faces. Sharps have several ways of falsifying dice: 1. By sticking a hog's bristle in them so as to make them run high or low as they please. 2. By drilling and loading them with quicksilver; which cheat is found out by holding them gently by two diagonal corners; for if false the heavy sides will turn down. 3. By filing and rounding them. But all these ways fall short of the art of the dice makers; some of whom are so dexterous, that sharpening gamblers will give any money for their assistance.

**DIET**, in Medicine, comprehends the whole regimen or rule of life, with regard to the six non-naturals; air, meats and drinks, sleep and watching, motion and rest, passions of the mind, retentions and excretions. Or it may merely imply eating and drinking, or solid aliments and liquids.

**DIETETICS**, the Science or Philosophy of Diets: that which teaches us to adapt particular foods to particular organs of digestion, or to particular states of the same organs; so that the greatest possible portion of nutriment may be extracted

from a given quantity of nutritive matter; or a sufficient portion may be obtained with the least possible quantity of organic action and exhaustion.

**DIFFERENCE**, is the remainder, after taking the less of two quantities from the greater.

**DIFFERENCE of Longitude** of two places, is an arc of the equator contained between the meridians of those places.

**DIFFERENTIAL**, in the higher Geometry, is an infinitely small quantity, or part of quantity, so small as to be less than any assignable one, and is thus denominated, because it is frequently considered as the difference of two quantities, and as such is the foundation of the differential calculus.

**DIFFERENTIAL Calculus**, is a method of differencing quantities, or of finding an infinitely small quantity, which being taken infinite times shall be equal to a given quantity; or it is the arithmetic of the infinitely small differences of variable quantities; and thus differs in its metaphysics from the fluxional calculus, those quantities which in the former are considered as infinitely small differences, being in the latter supposed to be the infinitely small or momentary increments of variable or flowing quantities.

**DIGESTER**. The digester is an instrument invented by Mr. Papin about the beginning of the last century. It is a strong vessel of copper or iron, with a cover adapted to screw on with pieces of felt or paper interposed. A valve with a small aperture is made in the cover, the stopper of which valve may be more or less loaded, either by actual weights, or by pressure from an apparatus on the principle of the steelyard. The purpose of this vessel is to prevent the loss of heat by evaporation. The solvent power of water when heated in this vessel is greatly increased. Papin's digester was constructed on the principle of mechanical pressure being necessary to elevate fluids to higher temperatures than their common boiling points.

A is the boiler; B the lid, fastened down by four screws; C a valve to allow the escape of a small portion of steam, to prevent the bursting of the apparatus; D is a notched lever, on which a weight E hangs, to prevent the valve from rising by a slight expansion of the steam. The weight is heavy according to the strength and thickness of the iron of which the digester is formed. The whole apparatus is generally made very strong, to prevent accidents. Animal bones are dissolved with great facility in these digesters, in order that the gelatine confined in them may be converted into rich soups, &c. For this purpose, they have been much used in hotels, coffee-houses, and family establishments. The heat of the water contained in this apparatus, is so intense as to melt lead.

**DIGESTION**, in Medicine, is the dissolution of the aliments into such minute parts as are fit to enter the lacteal vessels and circulate with the mass of blood. The food is first conveyed to the stomach, where by means of the gastric juice it is converted into chyme. The chyme passes into the intestinal canal, where it is subjected to a new process, being gradually decomposed and converted into chyle and excrementitious matter, which by means of the bile are separated from each other. The excrementitious matter is evacuated, but the chyle is absorbed by the lacteals, and conveyed to the blood vessels by the lungs.

**DIGGING**, among miners, the operation of freeing ore from the stratum in which it lies, where every stroke of their tools turns to account: in contradistinction to the openings made in search of such ore, which are called hatches or essay-hatches, and the operation itself, tracing of mines, or hatching.

**DIGITS**, or **MONADES**, in Arithmetic, signify any integer under 10, as 1, 2, 3, 4, 5, 6, 7, 8, 9.

**DIGGLES**, **LEONARD**, an English mathematician, born at Barham, in Kent, and educated at University college, Oxford, wrote a treatise on "Surveying," "Geometry," and "Prognostication everlasting of right good Effect," or, "Choice Rules to judge the Weather by Sun, Moon, and Stars," &c. He died about 1574.

**DIGGLES**, **Thomas**, son of the preceding, educated at Oxford, after which he became muster-master-general of the forces sent

by queen Elizabeth to the Netherlands. He wrote some military pieces, and some on astronomy, and other subjects of mathematics. He died in 1595.

**DIGIT**, in Arithmetic, signifies any one of the ten numerals, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0. The word comes from *digitus*, a finger; thus indicating the humble means originally employed in computations. **DIGIT**, is also a measure equal to three-fourths of an inch.

**DIGIT**, in Astronomy, is the measure by which we estimate the quantity of an eclipse. The diameter of the sun or moon's disc is conceived to be divided into 12 equal parts, called digits; and according to the number of those parts or digits which are obscured, so many digits are said to be eclipsed. When the luminary is wholly covered, the digits eclipsed are precisely 12; and when it is more than covered, as is frequently the case in lunar eclipses, then more than 12 digits are said to be eclipsed.

**DIKE**, or **DYKE**, a ditch or drain; and also a work of stone, timber, or fascines, raised to oppose the passage of the waters of the sea, a lake, river, or the like.

**DILAPIDATION**, is where an incumbent of a church living suffers the parsonage-house or out-houses to fall down, or be in decay for want of necessary reparations; or it is the pulling down or destroying any of the houses or buildings belonging to a spiritual living, or destroying of the woods, trees, &c., appertaining to the same; for it is said to extend to committing or suffering any wilful waste, in or upon the inheritance of the church.

**DIMENSION**, in Geometry, is either length, breadth, or thickness. Thus a line has only one dimension, *length*; a surface two, *length* and *breadth*; and a body or solid, *length*, *breadth*, and *thickness*.

**DIMENSION** of an *Equation*, or any other quantity in Algebra, is used with regard to the highest power that enters into its composition; thus an equation is said to be of one, two, three, &c. dimensions, according as it involves the simple quantity, the square, cube, &c.; so that a simple equation is of one dimension, a quadratic of two, a cubic of three, &c.

**DIMINUTION**, in Architecture, a contraction of the upper part of a column, by which its diameter is made less than that of the lower part.

**DIMINUTION**, in Law, where the plaintiff or defendant in a writ of error, alleges, on an appeal to a superior court, that part of the record is omitted, and remains in the inferior court not certified; whereon he prays that it may be certified by certiorari.

**DIMINUTION**, in Music, when there are several words, which are to make tones, and several quick motions in a cadence, several quavers, semiquavers, &c., corresponding to a crotchet or minim, as when a semibreve is divided into two minims, four crotchets, &c.

**DIMINUTIVE**, in Grammar, a word formed from some other, to diminish the force of it, or to signify a thing is little in its kind. Thus *Hal* is a diminutive of *Henry*.

**DINOCRATES**, a celebrated Macedonian architect, who flourished in the time of Alexander.

**DIOCESE**, the circuit of every bishop's jurisdiction. For this realm hath two sorts of divisions; one into shires or counties, in respect to the temporal state; and another into provinces, in regard to the ecclesiastical state, which provinces are divided into dioceses. The provinces are two, Canterbury and York; whereof Canterbury includes twenty-one dioceses, or sees of suffragan bishops; and York three, besides the bishopric of the Isle of Man, which was annexed to the province of York by king Henry the Eighth.

**DIONÆA MUSCEPULA**, or *Venus's Fly-Trap*, in Botany, a sensitive plant, in the construction of which nature seems to have had some view towards its nourishment, in forming the upper joint of its leaf like a machine to catch food; and placing upon the middle of it the bait for the insect that becomes its prey. The plant is of the monogynia order, in the decandria class. It grows in America, in wet shady places, and flowers in July and August; the glands of those exposed to the sun are of a beautiful red colour, but those in the shade are of a pale green. The roots are squamous, sending forth few fibres, and are perennial. The leaves are numerous, and placed in a cir-

cular order, jointed and succulent; the upper joints consist of two lobes, of a semi-oval form, with the margins furnished with stiff hairs, which lock in each other when they close; the upper surfaces of these lobes are covered with red glands, each of which appears, when highly magnified, like a compressed arbutus berry. The stalk is about six inches high, round, smooth, and without leaves, ending in a spike of flowers, milk-white, and standing on footstalks, at the bottom of which is a little painted bractea or flower-leaf.

**DIONYSIUS**, an ancient geographer, supposed to have flourished in the time of the first Augustus Caesar.

**DIOPHANTINE ANALYSIS**, or *Problems*, in Algebra, are certain questions relating to square, cube, &c. numbers, and rational right-angled triangles; the properties of which were first discussed by Diophantus, in his "Arithmetic."

**DIOPTRICS**, or **ANACLASTICS**, the doctrine of refracted vision, which investigates and explains the effects of light refracted by passing through different mediums, as air, water, glass, &c. and particularly lenses. See **REFRACTION** and **LENS**.

**DIP** of the **Horizon**, is an allowance made in all astronomical observations of altitude for the height of the eye above the level of the sea.

**DIPHTHONG**, in Grammar, a double vowel, or the mixture of two vowels pronounced together so as to make one syllable.

**DIPLOMATICS**, a word derived from diploma, in this instance signifying the king's letters patent, for the immediate expediting of an ambassador or envoy to a foreign court. The art of diplomatics has been cultivated with great assiduity by every nation in Europe for very many years past, and men experienced in political history, of engaging manners, and possessing a considerable share of duplicity, have always been selected by each to practise it.

**DIPPING**, among Miners, signifies the interruption of a vein of ore; an accident that gives them a great deal of trouble before they can discover the ore again.

**DIPPING NEEDLE**, or **INCLINATORY NEEDLE**, a magnetical needle, so hung, as that, instead of playing horizontally, and pointing north and south, one end dips or inclines to the horizon, and the other points to a certain height above it, as shewn in the following results of several of the most accurate experiments that have yet been made on this subject.

| LATITUDES<br>North. | LONGITUDES<br>East. | DIP of the NORTH<br>END of the NEEDLE. | DATES of<br>Observation. |
|---------------------|---------------------|----------------------------------------|--------------------------|
| 53° 55'             | 193° 39             | 69° 10'                                | 1778                     |
| 49 36               | 233 10              | 72 29                                  |                          |
|                     | West.               |                                        |                          |
| 52 24               | 83 30               | 79 17                                  | 1775                     |
| 44 5                | 8 10                | 71 34                                  | 1776                     |
| 38 53               | 12 1                | 70 30                                  |                          |
| 34 57               | 14 8                | 66 12                                  |                          |
| 29 18               | 16 7                | 62 17                                  |                          |
| 24 24               | 18 11               | 59 0                                   |                          |
| 20 47               | 19 36               | 56 15                                  |                          |
| 15 8                | 23 38               | 51 0                                   |                          |
| 12 1                | 23 35               | 48 26                                  |                          |
| 10 0                | 22 52               | 44 12                                  |                          |
| 5 2                 | 20 10               | 37 25                                  |                          |
| South.              |                     |                                        |                          |
| 0 3                 | 27 38               | 30 3                                   |                          |
| 4 40                | 30 34               | 22 15                                  |                          |
| 7 3                 | 33 21               | 17 57                                  |                          |
| 11 25               | 34 24               | 9 15                                   |                          |
|                     | East.               | South and below.                       |                          |
| 16 45               | 208 12              | 29 28                                  |                          |
| 19 28               | 204 11              | 41 0                                   |                          |
| 21 8                | 185 0               | 39 1                                   | 1777                     |
| 35 55               | 18 20               | 45 37                                  | 1774                     |
| 41 5                | 174 13              | 63 49                                  | 1777                     |
| 45 47               | 166 18              | 70 5                                   | 1773                     |

The inventor of this instrument was one Robert Norman, a compass maker, of Wapping, about the year 1576.

Some have endeavoured to find the latitude and longitude of

places by means of the dipping needle, particularly Burrowes, Gilbert, Bond, Whiston, &c.; but as nothing of importance followed from their attempts, it would be useless to enter upon any explanation of their particular methods in this place. But the following general rule may be adopted:—In order to find the longitude or latitude by the dipping needle. If the lines of equal dip, below the horizon, be drawn on maps, or sea charts, from good observations it will be easy, from the longitude known, to find the latitude; and from the latitude known, to find the longitude. Suppose, for example, you were travelling or sailing along the meridian of London, and found the angle of dip, with a needle of one foot, to be  $75^\circ$ , the chart will shew, that this meridian and the line of dip meet in the latitude of  $53^\circ 11'$ ; which therefore is the latitude sought. Or suppose you were travelling or sailing along the parallel of London, i. e. in  $51^\circ 32'$  north latitude, and you find the angle of dip to be  $74^\circ$ . This parallel, and the line of this dip will meet in the map in  $1^\circ 46'$  of east longitude from London, which is therefore the longitude sought.

**DIRECT**, a term frequently used in Arithmetic, Astronomy, Optics, &c. to denote some peculiar condition or circumstance, as *Direct Proportion*, *Ratio*, *Rays*, *Vision*, &c. for which see the respective substances.

**DIRECT**, in Astronomy. See **CONSEQUENTIA**.

**DIRECT Dial**, is one which points directly to any one of the four cardinal points, and is hence called *direct east*, *west*, *north*, or *south dial*, according to the point towards which it is directed.

**DIRECT Sphere**. See **RIGHT Sphere**.

**DIRECTION**, in Astronomy, the motion and other phenomena of a planet when direct.

**Line of DIRECTION**, in Gunnery, is the direct line in which the piece is pointed; and, in Mechanics, the same term implies the line in which a body moves, or in which a force is applied. When two conspiring forces act on a body at the same time, the angle included between the lines of their direction is called the *angle of direction*.

**Number of DIRECTION**, in the Calendar, is the number of days that Septuagesima Sunday falls after the seventeenth day of January.

**Quantity of DIRECTION**, in Mechanics, is a term sometimes used to denote what is more commonly called *Momentum*.

**DIRECTLY**, is used in nearly the same sense as direct; thus we say, quantities are directly proportional, which is only another way of stating them to be in direct proportion; and in Mechanics, one body is said to impinge directly upon another, when the former strikes the latter perpendicular to its surface.

**DIRECTRIX**, in the Conic Sections, is a certain right line perpendicular to the axis of the curve, and frequently referred to in treating of the properties of those figures, from the description of them in plano.

**DIRECTRIX**, or *Divigent*, is also that line or plane along which another line or plane is supposed to move, in the generation of a surface or solid.

**DISABLED**, the state of a ship when, by the loss of her masts, sails, yards, or rigging, by springing a leak, receiving some fracture in the hull, or other disaster, she is rendered incapable of prosecuting her voyage without great difficulty and danger.

**DISC**, the face of the sun or moon, as either luminary appears to the naked eye.

**Disc**, in Optics, is the width of the aperture of telescope glasses, whether plane, convex, concave, &c.

**DISCHARGE OF FLUIDS**, through apertures in the sides and bottoms of vessels, is a subject which has engaged the attention both of theorists and experimentalists; and may be considered under either point of view. We shall first state the principal propositions in the theoretical part of the subject, and then give some of the most remarkable and accurate experiments, by Bossut, Venturi, Eytelwein, Vince, Young, Leslie, &c.

1. If a fluid runs through a pipe or tube of an uniform shape, equal quantities of it will pass through every parallel section of the tube. This is evident, because the same quantity of fluid must pass through the same section in the same time. But though the water runs with the same velocity through

every section of the tube, it does not run with equal velocity through every part of the same section. Its motion is swiftest towards the middle, and slower towards the sides of the tube, where it is retarded by friction.

2. If a fluid runs through a tube or pipe, kept constantly full by means of a proper supply, but which is not of uniform shape; then the velocity of the fluids, in different sections, will be inversely as the areas of the sections. For since the tube is always full, the same quantity of water must pass through every section of it in the same time; but if the area of one section be half as great as the area of another section, the same quantity of water cannot pass through both sections at the same time, unless it pass through the former section with double the velocity with which it passes through the latter. If the area of the former section be one-third, or one fifth, of the area of the latter, the same quantity of water must pass through the former with a velocity which is three times, or five times, the velocity with which it passes through the latter. Hence the velocities must be inversely as the areas of the sections.

3. If a fluid, flowing through a small orifice in the bottom of a vessel, be kept constantly full by an uniform supply at the top, the velocity of the discharging fluid will be equal to that acquired by a heavy body in falling freely through the height of the surface of the fluid above the orifice.

Let MNOP represent a vessel filled with a non-elastic fluid up to the level of IK; MP, the bottom in which is the aperture CD (very small in comparison with MP), CIKD the column of the fluid standing directly above the aperture, and CABD the lowest lamina of the fluid immediately contiguous to the aperture. Also let  $v$  denote the velocity which a heavy body would acquire in falling freely through BD, the height of the lamina; and  $V$  the velocity acquired by the same lamina during its descent

through the same space until it is discharged by the pressure of the column CIKD. If we suppose the lowest lamina of fluid ACDB, to fall as a heavy body through the height BD, its moving orifice will be its own weight. Again, suppose it to be accelerated by its own weight, together with the pressure of the ambient fluid, about the column CIKD; viz. by the weight of the column CIKD through the same space; that is, while it is accelerated from quiescence until it is actually discharged: then the velocity in the former case will be to that in the latter, as the moving forces and the times in which they act directly, and the quantities of matter moved inversely. But the moving forces are to each other, as the heights BD and KD; the times in which they act are inversely as the velocities, the space through which the body is accelerated being given; and the quantities of matter moved are

equal; therefore  $v : V :: \frac{BD}{v} : \frac{KD}{V}$ ; whence  $v^2 : V^2 :: BD :$

$KD$ , or  $v : V :: \sqrt{BD} : \sqrt{KD}$ .

Now  $v$  is the velocity which a heavy body would actually acquire in falling through the space BD; consequently  $V$ , the velocity of the discharging fluid, is that which a heavy body would acquire in falling through KD, the whole altitude of the fluid above the orifice.

4. In the same manner it may be shown that if a pipe be inserted horizontally in the vessel MNOP the plate of fluid ACB will be discharged with the same velocity as before (if its centre of pressure be of the same depth), whatever be the thickness of the plate; this velocity not depending upon a continual acceleration through the length of the tube, otherwise the effluent fluid could not attain its full velocity, until a column had been discharged whose base is equal to the orifice, and height equal to the length of the tube; whereas we find by experience, that this full velocity can be attained by the thinnest plate which can be let escape from the aperture.

5. The velocities and quantities discharged at different depths, are as the square roots of the depths.

6. The quantity run out in any time is equal to a cylinder, or prism, whose base is the area of the orifice, and its altitude the space described in that time by the velocity acquired by falling through the height of the fluid. So that if  $h$  denote the height of the fluid,  $a$  the area of the aperture,  $g = 32\frac{1}{2}$  ft, or 386 inches, and  $t$  the time of efflux, we shall have, for the quantity discharged,  $Q = at \sqrt{2gh}$ ,—or,

When  $a$  and  $h$  are expressed in feet,  $Q = 8.0208 at \sqrt{h}$  feet.

When  $a$  and  $h$  are expressed in inches,  $Q = 27.7387 at \sqrt{h}$  inch.

If the orifice is a circle whose diameter is  $d$ , then  $0.785398 d^2$  must be substituted for  $a$ ;

And when  $d$  and  $h$  are expressed in feet,  $Q = 6.29952 d \sqrt{h}$  feet.

When  $d$  and  $h$  are expressed in inches,  $Q = 21.78592 d \sqrt{h}$  inches.

And from either of these it will be easy to find either  $a$ ,  $t$ , or  $h$ , when the other three quantities are given.

7. The force with which the effluent water impinges against any quiescent body, is proportional to the altitude of the fluid above the orifice. For the force is as the velocity multiplied by the quantity of matter; but the quantity discharged, in a given time, is as the velocity; therefore the force is as the square of the velocity; that is, by the demonstration of the proposition, (art. 3.) as the height of the fluid.

8. The water spouts out with the same velocity whether it be downwards, or upwards, or sideways; because the pressure of fluids is the same, in all directions, at the same depth.

9. When a vessel is left to discharge itself gradually, through an orifice in its bottom, if the area of the section parallel to the bottom be every where the same, the velocity of the surface of the fluid, and consequently the velocity of the efflux, will be uniformly retarded. For (by prop. 2.) the velocity of the descending surface is to the velocity at the surface, as the area of the orifice to the area of the surface, which is a constant ratio; consequently, the velocity of the descending surface varies as the velocity at the orifice, or as the square root of  $h$ ; that is, the velocity of the descending surface varies, as the square root of the space which it has to describe: so that this exactly corresponds with the case of a body projected perpendicularly upwards, where the velocity is as the square root of the space to be described: whence, as the retarding force is constant in the instance referred to, it must also be constant in the case before us, and the retardation uniform. From this comparison we deduce the following obvious corollaries. The quantities of water in a prismatic vessel, discharged through an aperture in the bottom, decrease in equal times; as the series of odd numbers 1, 3, 5, 7, 9, &c. taken in an inverted order. The quantity of water contained in an upright prismatic vessel, is half that which would be discharged in the time of the entire gradual evacuation of the vessel, if the water be kept always at the same altitude.

10. If upon the altitude of the fluid in a vessel, as a diameter, we describe a semi-circle, the horizontal space described by the fluid spouting from a vertical orifice, at any point in the diameter, will be as the ordinate of the circle drawn from that point; the horizontal space being measured on the plane of the bottom of the vessel. When the aperture is vertical, and indefinitely small (as supposed here), the fluid will spout out horizontally with the velocity due to the altitude of the fluid above the orifice (by prop. 3); and this velocity, combined with the perpendicular velocity arising from the action of gravity, will cause every particle, and consequently the whole jet, to describe the curve of a parabola. Now the velocity with which the fluid is expelled from any hole, as  $G$ , is such as if uniformly preserved would carry a particle through a space equal to  $2BG$ , in the time of the fall through  $BG$ ; but, after quitting the orifice, it describes the parabolic curve, and arrives at the horizontal plane  $CF$  in the same time as a body would fall freely

through  $GD$ ; so that to find the distance  $DE$ , since the times are as the roots of the spaces, we have this analogy  $\sqrt{GB}:$

$$\sqrt{GD}::2BG:DE=\frac{2BG.\sqrt{GD}}{\sqrt{GB}}=2\sqrt{BG.GD}=2GH,$$

by the nature of the circle. And the same will hold with respect to any other point in  $BD$ . If the apertures be made at equal distances from the top and bottom of the vessel (kept full of fluid), the horizontal distances to which the water will spout from these apertures will be equal. For when  $DG = BG$ , we shall have  $2\sqrt{BG.GD}=2\sqrt{BG.GD}$ , and consequently  $DE$  the same in both cases. When the orifice is at the point bisecting the altitude of the fluid in the vessel, the fluid will spout to the greatest distance on the horizontal plane; and that distance, if measured on the plane of the bottom of the vessel, will be equal to the depth of the fluid in it. For  $IK$ , the ordinate from the centre  $I$ , is the greatest which can be drawn in the semi-circle, and  $DF$ , which is  $= 2IK$ , is then  $= 2BI = BD$ .

We have already extended this article, and therefore must be very brief in stating the results of the principal experiments that illustrate this interesting inquiry. With respect to the quantity of fluid discharged, Bossut's experiments, made with peculiar accuracy, demand particular notice. They are expressed in the following table, which exhibits the quantity of fluid discharged through orifices pierced in thin plates; in measures of the Paris foot royal, which is to the English foot, as 1066 to 1000.

| Constant Altitude of the Water in the Reservoir above the Aperture, in Paris Feet. | Theoretical Discharges in one Minute through a circular Aperture of Tin, expressed in Cubic Inches. | Real Discharges in the Time through the same Orifice, expressed also in Cubic Inches. |

From these experiments we may derive the following deductions; viz.

1. The quantities of fluid discharged, in equal times, from different sized apertures, the altitude of the fluids being the same, are to each other nearly as the areas of the apertures.

lomey's day 682, in the reign of Charles II. By this act, 2000 ministers of the establishment, refusing to conform to certain conditions, were obliged to quit their livings, and hence arose the name of Non-conformists. The descendants of these are known by the name of Protestant Dissenters: and may be considered, in general, as divided into the denominations of Presbyterians, Independents, and Baptists.

**DISSIPATION**, in Physics, an insensible loss or consumption of the minute parts of a body, or that agency whereby they fly off and are lost.

**Circle of DISSIPATION**, in Optics, denotes the circular space upon the retina, which is taken up by one of the extreme pencils of rays issuing from any object.

**Radius of DISSIPATION**, is the radius of the circle of dissipation.

**DISSOLVENT**, any thing which dissolves.

**DISSOLUTION**, the separation of a body into its most minute parts.

**DISTANCE**, in Astronomy, the space between the sun and any of the planets, &c. as shewn in the following table of the real and proportional distances of the several planets.

|               | Proportional<br>Mean Dist. | Real<br>Mean Dist. |                                      |

**DISTANCE** of the *Fixed Stars* from the Earth or Sun, has never yet been determined; we only know it is so great, that the whole diameter of the earth's orbit, which is near two hundred million miles, is but as a point compared with their distance, and therefore forms no sensible measure whereby it may be estimated.

**DISTANCE** of the *Sun* from the Moon's Node or Apogee, is an arch of the ecliptic intercepted between the sun's true place and the moon's node or apogee.

**Accessible DISTANCES**, are such as may be measured by the application of any lineal measure. **Inaccessible DISTANCES**, are those which cannot be measured by the application of any lineal measure, but by means of angles and trigonometrical rules and formulæ. See **ACCESSIBLE**.

The distance of objects may also be ascertained by means of sound; for as this has been found, by experiment, to travel at the rate of about 1142 feet per second, if the time which elapses between the firing of a gun and the report of the same be duly observed, the distance in feet will be found by multiplying the number of seconds by 1142; and in this way we may estimate the distance of a thunder cloud, by the number of seconds being observed that elapses between the flash of lightning, and the clap of thunder by which it is succeeded. See **ACOUSTICS**.

**Apparent DISTANCE**, in Optics, is that distance at which we judge an object to be placed when seen afar off, and which is usually very different from the true distance, because we are apt to think that all very remote objects whose parts cannot well be distinguished, and which have no other object in view near them, are at the same distance from us, though perhaps one of them is thousands of miles nearer than the other, as is the case with the sun, moon, and planets.

The most universal, and frequently the most sure means of judging of the distance of objects, is the angle made by the optic axis. For our two eyes are like two different stations, by the assistance of which distances are taken; and this is the reason why those persons who are blind of one eye so frequently miss their mark in pouring liquor in a glass, snuffing a candle, and such other actions as require that the distance be exactly distinguished. To convince ourselves of the usefulness of this method of judging of the distance of objects, we have only to suspend a ring in a thread, so that its side may be

towards us, and the hole in it to the right and left hand; and taking a small rod, crooked at the end, retire from the ring two or three paces, and having with one hand covered one of our eyes, to endeavour with the other to pass the crooked end of the rod through the ring. This appears very easy, and yet upon trial, perhaps once in 100 times we shall not succeed, especially if we move the rod a little quickly. By persons recollecting the time when they began to be subject to the mistakes above mentioned, they may tell when it was that they lost the use of one of their eyes, which many persons are long ignorant of, and which may be a circumstance of some consequence to a surgeon. The use of this second method of judging of distances, De Chales limits to 120 feet, beyond which, he says, we are not sensible of any difference in the angle of the optic axis.

A third method of judging of the distance of objects consists in their apparent magnitudes. From this change in the magnitude of the image upon the retina, we easily judge of the distance of objects, as often as we are otherwise acquainted with the magnitude of the objects themselves; but as often as we are ignorant of the real magnitude of bodies, we can never, from their apparent magnitude, form any judgment of their distance.

From this we may see why we are so frequently deceived in our estimates of distance, by any extraordinary magnitudes of objects seen at the end of it, as in travelling towards a large city, or a castle, or a cathedral church, or a mountain larger than ordinary, we fancy them to be nearer than we find them to be. This also is the reason why animals, and all small objects seen in valleys contiguous to large mountains, appear exceedingly small. For we think the mountain nearer to us than if it were smaller, and we should be surprised at the smallness of the neighbouring animals, if we thought them farther off. For the same reason we think them exceedingly small when they are placed on the top of a mountain, or a large building, which appears nearer to us than it really is, on account of its extraordinary size.

Our imagining objects, when seen from a high building, to be smaller than they are, and smaller than we fancy them to be when we view them at the same distance on level ground, is because we have no distinct idea of distance in that direction, and therefore judge of the things by their pictures upon the eye only, but custom will enable us to judge rightly even in this case. Let a boy who has never been upon a high building, go to the top of the Monument, and look down into the street; the objects seen there, as men and horses, will appear so small as greatly to surprise him. But ten or twenty years after, if in the mean time he has used himself now and then to look down from that and other great heights, he will no longer find the same objects to appear so small. The finest sight of this nature is from a balloon. See **AEROSTATION**. We have had a very fine sight ourselves of this nature, in surveying from the lofty spire of St. Denis, in France, a large army in the plain between that cathedral and Paris. And if a person were to view the same objects from such heights as frequently as he sees them upon the same level with himself in the streets, they would appear to him just of the same magnitude from the top of the Monument as they do from a window one story high. For this reason it is, that statues placed upon very high buildings ought to be made of a larger size than those which are seen at a nearer distance, because all persons, except architects, are apt to imagine the height of such buildings to be much less than it really is.

The fourth method by which we judge of the distance of objects, is the force with which their colour strikes upon our eyes. For if we be assured that two objects are of a similar and like colour, and that one appears more bright and lively than the other, we judge that the brighter object is the nearer of the two.

The fifth method consists in the different appearance of the small parts of objects. When these parts appear distinct, we judge that the object is near; but when they appear confused, or when they do not appear at all, we judge that it is at a greater distance. For the image of any object, or part of an object, diminishes as its distance from our eye increases.

The sixth and last method by which we judge of the distance

of objects is, that the eye does not represent to our mind one object alone, but at the same time all those that are placed betwixt us and the principal object, whose distance we are considering; and the more this distance is divided into separate and distinct parts, the greater it appears to be. For this reason, distances upon uneven surfaces appear less than upon a plane; for the inequalities of the surface, such as hills, and holes, and rivers, that lie low and out of sight, either do not appear, or hinder the parts that lie behind them from appearing; and so the whole apparent distance is diminished by the parts that do not appear in it. This is the reason that the banks of a river appear contiguous to a distant eye, when the river is low and not seen. How much narrower does a river that is subject to the influence of the tide appear at low water, than when its bosom is proudly swelled at high water mark? and yet perhaps the actual breadth at both times does not vary 20 feet.

**DISTANCE**, in Navigation, is the number of miles or leagues that a ship has sailed from one point to another.

**Line of DISTANCE**, in Perspective, is a right line drawn from the eye to the principal point of the plane. **Point of DISTANCE**, in Perspective, is that point in the horizontal line which is at the same distance from the principal point as the eye is from the same.

**DISTANCE OF THE EYE**, in Perspective, is a line drawn from the eye to the principal point.

**DISTEMPER**, in Painting, a term used for the working up of colours with something besides water or oil. If the colours are prepared with water, that kind of painting is called limning; and if with oil, it is called painting in oil, and simply painting. If the colours are mixed with any glutinous or unctuous matter instead of oil, it is said to be done in distemper. In this manner the cartoons at Windsor are painted.

**DISTICH**, a couplet of verses making a complete sense. Thus hexameter and pentameter verses are disposed in distichs.

**DISTILLATION**. Under the article **CHEMISTRY**, we explained what distilling means, and how it is performed; the subject of the present article is confined to the making of ardent spirits, or alcohol,—the distillation of gases belonging to another part of our work.

Previously to the operation of distilling, those of brewing and fermentation are necessary; the liquid must be brought into the state of wine, or beer, (which is the wine of grain.) Methods have been suggested, and we believe carried into practice, for reducing the brewing and fermentation to a single operation, by which, it is said, the spirit is much improved in quality, as well as augmented in quantity. The practice, we are informed, is as follows:—

To one hundred pounds of malt, reduced to fine meal, are added, thirty pounds of wheat meal; twenty gallons of water are then added by degrees, mixing the whole mass thoroughly; fifty gallons more of water, made boiling hot, are then poured upon the mass, and the whole well stirred together. It is then allowed to stand for two hours, afterwards stirred again, and when grown cold, a pound or more of solid yeast is added, and then allowed to stand loosely covered in rather a warm place to ferment.

In London, and its neighbourhood, we understand the process of forming the wash for distillation is the same as in brewing for beer, with the exception of the addition of the hops, and that instead of boiling the wort, they pump it into coolers, and afterwards draw it into backs, to be then fermented with yeast. During the fermentation, particular attention must be paid to the temperature of the liquid: if it exceeds 77° Fahrenheit, the fermentation will be too rapid; if below 60°, the fermentation will cease. The mean between these is considered the most favourable, and the fermentation must be continued until the liquor grows fine and pungent to the taste, but not so long as to permit the acetous fermentation to commence. In this state the wash is put into the still, of which it should occupy about three-fourths, and distilled with a gentle fire, as low as any spirit comes over, which is generally until about half the wash is consumed.

The form of the common still is too well known to need any particular description; it generally consists of a large boiler made of copper, and fixed in masonry over a fireplace; the

boiler has a head, or capital as it is called, which is of a globular form, to which is soldered a neck, which forming a complete arch, curves downward, and fits into what is called the worm. The worm is a long tube, made generally of pewter, of a gradually decreasing diameter, and is curled round into a spiral form; it is enclosed in a tub, which is kept filled with cold water during distillation.

The Dutch method of making Geneva is said to be as follows:—"One hundred weight of malt from barley, and two hundred weight of rye meal, are mashed, with four hundred and sixty gallons of water, heated to 162° Fahrenheit. When the infusion has been continued a sufficient time, cold water is added until the wort is equivalent to about forty-five pounds of saccharine matter per barrel; it is then drawn off into a back of five hundred gallons' capacity, at the temperature of 80°, with half a gallon of yeast. The fermentation immediately commences, and is generally finished in about two days, when proper attention is paid to the temperature of the place. The wash is then put into the still, reduced to about fifteen pounds of saccharine matter per barrel, along with the grains, and receives three distillations, a few juniper berries, and a small quantity of hops, being introduced to communicate the flavour required."

The spirits of the first distillation is usually called *low wines*; the re-distillation of the *low wines*, or *doubling*, produces at first a fiery spirit, milky and crude, (which is returned into the low wines); after this the spirit flows perfectly clear and bright; nevertheless, tainted a little with empyreuma, to get rid of which it generally undergoes another distillation called rectification, at which time flavouring ingredients are added, to imitate the foreign spirits, such as rum, brandy, holland, gin, &c. and likewise to form the compound spirits, called caraway, peppermint, cinnamon, cloves, aniseed, &c.

The flavour of malt spirit is said to be much improved, by putting four ounces of finely-powdered charcoal, and four ounces of ground rice, into a quart of spirits, and letting it stand for a fortnight, frequently stirring it; upon being then strained, it will be found to resemble very closely the flavour of brandy. It has been frequently proved, that the muriate of soda (or common salt) thrown into the still in the proportion of about half an ounce to every gallon, will materially improve the taste and strength of the spirit; the viscid matter being fixed by the salt, allows the volatile parts to ascend in greater purity. Some time since, a distiller at Copenhagen published an account of his having several times distilled brandy and gin from wheat steeped in salt water, by which he uniformly obtained nearly one-fourteenth more of spirit, than when he distilled from an equal quantity of wheat, which had not undergone that process.

It is said to be the practice of the distillers in Scotland, &c. to use one part of malted grain, with from four to nine parts of raw grain; rye is said to produce more spirit than wheat, and wheat more spirit than barley.

**WINTER'S Distilling Apparatus**, exhibited in the annexed figures, is constructed on the principle of condensing the aqueous portion of the mixed liquor previously to its passing

into the still. A, in this sectional view, is a tube by which the vapours enter from the still into B the receiver. C is a conical plate. D the chief vapour tube, which being closed at the top, the vapours descend by the small tubes G, into the chamber F. The apparatus is isolated in water of 170° temperature, contained in the tub or bath T, and as the vapours contained in the tubes are by this arrangement separated into small portions, a rapid condensation takes place. A number of circular tubes, as at H, are fixed in the plate which covers the receiver B, with their upper ends a little above the surface. These carry off the condensed liquor into the receiver B. The vapour, now improved in its spirit, is collected in the chamber F, and passes by the tube I

into the second receiver K. The top plate of this second receiver K, as well as the bottom plate of the third receiver N, have numerous apertures of concentric circles as at L L, in the following figure, into each of which are fitted two copper cylinders, one within the other, and only about a quarter of an inch apart. And as there are four such apertures, there are consequently eight pairs of apertures.

Into each of these annular apertures L, L, are fixed two copper cylinders, one within the other, and only about a quarter of an inch apart; and as there are four such apertures, there are consequently eight cylinders or four pairs in the apparatus, which are exhibited in section in the first engraving at M, M. O, O are tubes which pass through the receiver K, to convey water between the cylinders; similar tubes are passed through the receiver N, by which means the water is diffused over every part of the extended surface of the apparatus, effecting thereby almost as rapid a condensation of the aqueous portion of the vapour, as if the water were in actual contact with it. The vapours passing from the lower receiver K, ascend, as before mentioned, through the narrow spaces between the cylinders into the upper receiver N, in a high state of purity and strength; from this last hold it proceeds into the worm by the tube P, where it is instantly condensed by the refrigerating effect of the cold water with which this part of a distillatory apparatus is always surrounded.

It is, perhaps, not unnecessary to repeat, that the water contained in the second bath T, shewn in section, is heated to  $140^{\circ}$  (or less, as the spirit may be required,) that being a degree of temperature to which the vapour of water, as well as those from the empyreumatic oils, cannot exist. The spirit is thus separated effectually, and without any difficulty, from the least taint of empyreuma, with which British spirits are in general more or less contaminated.

It will be observed, that this second receiver is of a peculiar construction, and being kept at a temperature of  $140^{\circ}$ , the whole of the weaker vapour is therein reduced into a liquid state, while the strong spirituous vapour, ascending alone through certain very narrow spaces, contained between the circuitous cylinders, into the deeper part of the apparatus, is thence collected into a third receiver previously to its passing into the worm. The worm is surrounded as usual with cold water, whose powerful refrigerating effects upon the strong spirituous vapour with which it is charged, causes it rapidly to pass into a fluid state. In this still the spirit might be rectified or flavoured, by allowing the vapours to pass through the necessary ingredients as they pass on to the worm. We need not speculate on the advantages of this apparatus, which is manufactured by Messrs. Pontifex, Sons, and Co. London.

**DISTILLATION by a low heat, in close vessels.** Those who are acquainted with the common method of distilling, know that a very unpleasant flavour accompanies all distilled products, occasioned by the matter in the still being overheated, or burned. The late James Watt ascertained, that liquids boiled at a very low temperature in vacuo, or by emptying the apparatus of atmospheric air; and Mr. Tretton, of Whitechapel, London, ingeniously applied this fact to distillation, and constructed the annexed apparatus, wherein the body of the still is seen as immersed in a water bath, which renders it impossible to overheat or burn the liquid, or communicate the disagreeable empyreumatic flavour to spirit, as is done by the common

still. A is the body of the still; B is a water bath, into which the body of the still is immersed; C is the head, or capital; D is the neck of the same, which, curving downwards, is connected with a pipe that enters the condensing vessel E; F is a refrigeratory, or close vessel, containing cold water, for converting into liquid the spirituous vapours, which having been raised in the still, are contained in the vessel E. From the bottom of the vessel E a pipe issues for conveying the liquid, and the vapour not yet condensed, into vessel G, which being surrounded with cold water contained in the vessel H, acts also as a refrigeratory, and reduces the whole of the remaining vapour into a liquid state. I is an air-pump for effecting a vacuum in the vessels A E G. K is a stop-cock for cutting off the communication between the vessels E and G, when the contents of G are drawn off by the cock M, by which means a vacuum is preserved, during that operation in the vessel E and the still A; L is an air-cock, to admit air into vessel G, to allow the contents to run out at M; N is a discharge-cock to the still A.

The pressure of the atmosphere being removed from the surface of the liquid by the air-pump, the distillation is effected at a temperature of  $132^{\circ}$  in place of  $212^{\circ}$ , and of course from the regular application of so low a degree of heat, an agreeable flavour is secured to the distilled product. Moreover, from the distillation being confined throughout the operation to close vessels, the common loss by evaporation at the end of the worm is avoided, and an increase of product is obtained.

**DISTINCT BASE**, in Optics, is the same with what is otherwise called the focus.

**DISTINCTION**, in Logic, is an assemblage of two or more words, whereby disparate things, or their conceptions, are denoted. There are three kinds of distinctions, taken from the three different modes of existence, real, modal, and rational. The first is that between two substances, or the modes of two substances. The second is that between several things, one whereof may exist without the other, but not vice versa. The third is that between several things which are really one and the same, and whereof one cannot exist without the other; nor, vice versa, the other without this; such is that between a thing and its essence, between the essences and properties, &c.

**DISTRESS**, in Law, is the taking of a personal chattel, out of the possession of the wrong doer, into the custody of the person who is injured, to procure a satisfaction for the wrong committed. It is of two kinds; cattle for trespassing and doing damage, or for the non-payment of rent or other duties. But the most usual injury for which a distress may be taken, is that of non-payment of rent.

**DISTRINGAS**, in Law, a writ commanding the sheriff, or other officer, that he distrain a person for debt to the king, &c. or for his appearance at a certain day. There is a great diversity of this writ.

**DITTON**, HUMPHREY, a mathematician of the seventeenth century, born at Salisbury, May 29, 1675, was author of several tracts which were published in the Philosophical Transactions.

**DIVERGENT**, tending to various parts from one point; thus we say, diverging lines, rays, &c. meaning those lines or rays which issuing from one common point, go off from that point in various directions.

**DIVERGING SERIES**, in Analysis, are those series, the terms of which increase more and more, the farther they are continued.

**DIVERSITY**, in Painting, consists in giving every part or figure in a piece its proper air and attitude.

**DIVIDEND OF STOCKS**, is a share or proportion of the interest of stocks erected on public funds, as the South Sea, &c. divided among, and paid to, the proprietors half yearly.

**DIVIDEND**, in Arithmetic, is that number which is to be divided by some other number called the divisor.

**DIVING**, the art of descending under water to considerable depths, and remaining there for some time in order to recover things which have been sunk, as also for the purpose of bringing up corals, pearls, sponge, &c.

**DIVING Bell**, an apparatus used for the purpose of diving. See **BELL**.

There have been various engines contrived to render the business of diving safe and easy: the great point, is to furnish the diver with fresh air, without which he must either make but a short stay or perish. Those who dive for sponges in the Mediterranean, carry down sponges dipped in oil in their mouths. But considering the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the pressure of the incumbent water, such a supply cannot subsist a diver long, since a gallon of air is not fit for respiration above a minute. Dr. Halley assures us, a naked diver cannot subsist above two minutes under water with or without a sponge; besides, if the depth be considerable, the pressure of the water makes the eyes blood-shot, and frequently occasions a spitting of blood.

An experiment was lately tried at Rouen upon a new invented diving machine, called *bateau-poisson*, or fishboat. This boat sunk of itself seven or eight minutes, and then rose of itself. The longest time it remained under water was eight minutes. The descent into the inside of this machine was by an opening made in the form of a tunnel, which was about a demimetre above the surface of the water. When those who conducted the experiment wished to descend altogether in the river and disappear, they let down this opening, sunk entirely under the water, and lost all communication with the external air. The inventor of this ingenious machine was Fulton. Three of his assistants went into the boat, and remained during the experiment. The prefect and a vast concourse of spectators were present.

**DIVING Bladder**, is a term used by Borelli, for a machine which he contrived for diving under the water to great depths, with great facility, and which is preferred to the common diving bell. The vesica, or bladder, as it is usually called, is to be of brass or copper, and about two feet in diameter. This is to contain the diver's head, and is to be fixed to a goat-skin habit, exactly fitted to the shape of the body of the person. Within this vesica there are pipes, by means of which a circulation of air is contrived; and the person carries an air-pump by his side, by means of which he may make himself heavier or lighter, as the fishes do, by contracting or dilating their air bladder.

**DIVISIBILITY**, an essential property of bodies. Every substance with which we are acquainted is capable of being separated into parts, and each of these again repeatedly subdivided. Nor has any limit ever been assigned to this process of continual subdivision, though it seems probable that, at some term, however distant, the resulting particles may lapse into simple *atoms*, incapable of any farther resolution.

The actual subdivision of bodies has, in many cases, been carried to a prodigious extent. A slip of ivory, of an inch in length, is frequently divided into an hundred equal parts, which are distinctly visible. But, by the application of a very fine screw, five thousand equidistant lines, in the space of a quarter of an inch, can be traced on a surface of steel or glass with the fine point of a diamond, producing delicate iridescent colours. Common writing paper has a thickness of about the 500th part of an inch; but the pellicle separated from ox-gut, and then doubled to form gold-beaters' skin, is six times thinner. A single pound of cotton has been spun into a thread 76 miles in length; and the same quantity of wool has been extended into a thread of 95 miles; the diameters of those threads being hence only the 350th and 400th parts of an inch.

But the ductility of some metals far exceeds that of any other substance. The gold-beaters begin with a riband an inch broad and 150 inches long, which has been reduced, by passing through rollers, to about the 800th part of an inch in thickness. This riband is cut into squares, which are disposed between leaves of vellum, and beat by a heavy hammer, till they acquire a breadth of more than three inches, and are therefore extended ten times. These are again quartered, and placed between the folds of gold-beaters' skin, and stretched out, by the operation of a lighter hammer, to the breadth of five inches. The same process is repeated, sometimes more than once, by a succession of lighter hammers; so that 376 grains of gold are thus finally extended into 2000 leaves, of 3.3

inches square, making in all 80 books, containing each 25 leaves. The metal is consequently reduced to the thinness of the 282,000th part of an inch, and every leaf weighs rather less than the fifth part of a grain.

Silver is likewise capable of being laminated, but will scarcely bear an extension above half that of gold, or the 150,000 part of an inch thick. Copper and tin have still inferior degrees of ductility, and cannot perhaps be beat thinner than the 20,000th part of an inch. These form what are called Dutch Leaf.

In the gilding of buttons, five grains of gold, which is applied as an amalgam with mercury, is allowed to each gross; so that the coating left must amount to the 110,000th part of an inch in thickness. If a piece of ivory or white satin be immersed in a nitro-muriate solution of gold, and then plunged into a jar of hydrogen gas, it will become covered with a surface of gold hardly exceeding in thickness the ten millionth part of an inch.

The gilt wire used in embroidery is formed by extending gold over a surface of silver. A silver rod, about two feet long and an inch and half in diameter, and therefore weighing nearly twenty pounds, is richly coated with about 800 grains of pure gold. In this country the lowest proportion allowed is 100 grains of gold to a pound of silver. This gilt rod is then drawn through a series of diminishing holes, till it has stretched to the vast length of 240 miles, when the gold has consequently become attenuated 800 times, each grain covering a surface of 9600 square inches. This wire being now flattened, the golden film suffers a farther extension, and has its thickness reduced to the four or five millionth part of an inch.

It has been asserted, that wires of pure gold can be drawn of only the 4000th part of an inch in diameter. But Dr. W. H. Wollaston, by an ingenious procedure, has lately advanced much farther. Taking a short cylinder of silver, about the third part of an inch in diameter, he drilled a fine hole through its axis, and inserted a wire of platinum only the 100th part of an inch thick. This silver mould was now drawn through the successive holes of a steel plate, till its diameter was brought to near the 1500th part of an inch, and consequently the internal wire, being diminished in the same proportion, was reduced to between the 4 and 5000th part of an inch. The compound wire was then dipped in warm nitric acid, which dissolved the silver, and left its core, or the wire of platinum. By passing the incrustated platinum through a greater number of holes, wires still finer were obtained, some of them only the 30,000th part of an inch in diameter. The tenacity of the metal, before reaching that limit, was even considerable; a platinum wire of the 18,000th part of an inch in diameter supporting the weight of one grain and a third.

Such excessive fineness is hardly surpassed by the filamentous productions of nature. Human hair varies in thickness, from the 250th to the 600th part of an inch. The fibre of the coarsest wool is about the 500th part of an inch in diameter, and that of the finest only the 1500th part. The silk line, as spun by the worm, is about the 5000th part of an inch thick; but a spider's line is perhaps six times finer, or only the 30,000th part of an inch in diameter, inasmuch, that a single pound of this attenuated substance might be sufficient to encompass our globe.

The red globules of the human blood have an irregular roundish shape, from the 2500th to the 3300th of an inch in diameter, with a dark central spot.

The trituration and levigation of powders, and the perennial abrasion and waste of the surface of solid bodies, occasion a disintegration of particles, almost exceeding the powers of computation. Emery, after it has been ground, is thrown into a vat filled with water, and the fineness of the powder is distinguished by the time of its subsidence. In very dry situations, the dust lodged near the corners and crevices of ancient buildings is, by the continual agitation of the air, made to give a glossy polish to the interior side of the pillars and the less prominent parts of those venerable remains. So fine is the sand on the adust plains of Arabia, that it is carried sometimes 300 miles over the Mediterranean, by the sweeping and violent Sirocco. Along the shores of that sea, the rocks are peopled by the *pholas*, a testaceous and edible worm, which,

though very soft, yet, by unwearied perseverance, works a cylindrical hole into the heart of the hardest stone. The marble steps of the great churches in Italy are worn by the incessant crawling of abject devotees; nay, the hands and feet of bronze statues are, in the lapse of ages, wasted away by the ardent kisses of innumerable pilgrims that resort to those shrines. What an evanescent pellicle of the metal must be abraded at each successive contact!

The solutions of certain saline bodies, and of other coloured substances, exhibit a prodigious subdivision and dissemination of matter. A single grain of the sulphate of copper, or blue vitriol, will communicate a fine azure tint to five gallons of water. In this case the copper must be attenuated at least ten million times; yet each drop of the liquid may contain as many coloured particles, distinguishable by our unassisted vision. A still minuter portion of cochineal, dissolved in deliquescent potash, will strike a bright purple colour through an equal mass of water.

Odours are capable of a much wider diffusion. A single grain of musk has been known to perfume a large room for the space of twenty years. Consider how often, during that time, the air of the apartment must have been renewed, and have become charged with fresh odour! At the lowest computation, the musk had been subdivided into 320 quadrillions of particles, each of them capable of affecting the olfactory organs. The vast diffusion of odorous effluvia may be conceived from the fact, that a lump of *assafetida*, exposed to the open air, lost only a grain in seven weeks. Yet, since dogs hunt by the scent alone, the effluvia emitted from the several species of animals, and from different individuals of the same race, must be essentially distinct.

The vapour of pestilence conveys its poison in a still more subtle and attenuated form. The seeds of contagion are known to lurk for years in various absorbent substances, which, on exposure to the air, scatter death and consternation.

But the diffusion of the particles of light defies all powers of calculation. A small taper will, in a twinkling, illuminate the atmosphere to the distance of four miles; yet the luminous particles which fill that wide concavity cannot amount to the 5000th part of a grain, which may be the whole consumption of the wax in light, in smoke, and ashes.

Animated matter likewise exhibits, in many instances, a wonderful subdivision. Between the Tropics, the small marine polypi, by the immensity of their combined numbers, speedily raise up clusters of coral reefs, so dangerous at present to the navigation of those seas, but which are destined, at no very remote period, to form groups of inhabited and cultivated islands. The milt of a codfish, when it begins to putrefy, has been computed to contain a billion of perfect insects; so that thousands of these living creatures could be lifted on the point of a needle. But the infusory animalcules display, in their structure and functions, the most transcendent attenuation of matter. The *vibrio undula*, found in duck-weed, is computed to be ten thousand million times smaller than a hemp seed. The *vibrio lineola* occurs in vegetable infusions, every drop containing myriads of those oblong points. The *monas gelatinosa*, discovered in ditch-water, appears in the field of a microscope a mere atom endued with life, millions of them playing like the sunbeams in a single drop of liquid.

Insects have been discovered so small as not to exceed the 10,000 part of an inch, so that 1,000,000,000,000 of them might be contained within the space of one cubic inch, yet each animalcule must consist of parts connected with each other, with vessels, with fluids, and with organs necessary for its motions, for its increase, for its propagation, &c. How inconceivably small must those organs be; and yet they are unquestionably composed of other parts still smaller, and still farther removed from the perception of our senses.

**DIVISION**, in the Navy, a select number of ships in a fleet or squadron of men-of-war, distinguished by a particular flag, pendant, or vane, and sometimes commanded by a general officer. A squadron is commonly ranged into three divisions, the commanding officer of which is always stationed in the centre. In a large fleet the admiral divides it into three squadrons, each of which is commanded by an admiral, and is again divided into three divisions; each squadron has its proper

colours, according to the rank of the admiral who commands it; and each division its proper mast. The private ships carry pendants of the same colour with their respective squadrons at the masts of their particular divisions, so that the ships in the last division of the blue squadron carry a blue pendant at their mizzen top-gallant-mast-head. These distinctions of divisions are not, however, constantly practised. The general officers or commanders of divisions place themselves in the centre of the divisions, the three commanding admirals excepted, who, in a sailing position, lead their respective squadrons.—In the Army, a body of troops composed of several brigades, and commanded by a general officer.

**DIVISION**, in Natural Philosophy, is the taking a thing to pieces, in order to have a more complete conception of the whole: this is frequently necessary in examining very complex beings, the several parts of which cannot be surveyed at one view.

**DIVISION**, is one of the principal rules in Arithmetic and Algebra: it consists in finding how often a less number is contained in a greater. The number to be divided is called the *dividend*, the number by which the division is made is the *divisor*; the number of times that this is contained in the former is called the *quotient*, and if any thing remains after the operation is finished, it is called the *remainder*. Division is either simple or compound.

**Simple DIVISION**, is when both the divisor and dividend are integral numbers.

**Rule**.—Draw a small curve line on the right and left of the dividend, and write the divisor on the left; then find how many times the divisor is contained in as many of the left-hand figures of the dividend as are just necessary, and place that number on the right. Multiply the divisor by this number, and place the product under the figure of the dividend above mentioned. Subtract this product from that part of the dividend under which it stands, and bring down the next figure of the dividend, or more if necessary, to the right of the remainder. Divide this number, so increased, as before, and so on till the whole is finished. *Note 1.* When it is necessary to bring down more than one figure to the remainder, a cipher must be placed in the quotient for every figure thus brought down. *2.* If the divisor do not exceed 12, the quotient may be written down as it arises, immediately under the dividend.—**Proof of DIVISION.** Multiply the divisor and quotient together, and add to this product the remainder, which ought to be equal to the dividend, if the work be right.

*Example.*

Sometimes, for the sake of abridging the operation, the successive products are omitted, and the subtraction is made figure for figure as the work is carried on; by this method, the foregoing example would stand as follows:—Division may also be proved by the cross, the same as multiplication, by casting out the nines from the divisor and quotient; and again out of the product of their remainders; and this last remainder ought to be the same as that arising from the dividend, after the remainder, arising in the operation, is subtracted from it; thus,

|                     |                                                                |
|---------------------|----------------------------------------------------------------|
| 346) 7486716 (21637 |                                                                |
| 566                 |                                                                |
| 2207                |                                                                |
| 1311                |                                                                |
| 2736                |                                                                |
| 314                 |                                                                |
| proof               |                                                                |
|                     | $\left\{ \begin{array}{cc} 4 & 1 \\ 4 & 4 \end{array} \right.$ |

This is generally called the *Italian method of division*.

**Compound Division**, is when the dividend is a compound quantity.—*Rule*. Divide the highest denomination of the dividend by the divisor, as in the former rule. Reduce the remainder, if any, to the next inferior denomination, and divide as before; reduce this remainder again, and divide as before; and so on till the whole is finished. *Note*. If the divisor exceed 12, and be a composite number, divide by its factors successively, instead of the whole number at once.

|                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                            |

**DIVISION of Fractions**, is performed by the following rule. Reduce all mixed numbers to improper fractions, then invert the terms of the divisor, and multiply the numerators and the denominators together as in multiplication, observing that such factors as are common in the numerators and denominators may be cancelled.

*Examples.*

|                                                                                                                                                                                                             |                                                                                                                                                                                                             |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>1. <math>\frac{7}{9} \div \frac{3}{4} = \frac{7}{9} \times \frac{4}{3} = \frac{28}{27}</math></p> <p>2. <math>\frac{3}{11} \div \frac{4}{9} = \frac{3}{11} \times \frac{9}{4} = \frac{27}{44}</math></p> | <p>3. <math>1\frac{6}{8} \div \frac{3}{4} = \frac{14}{8} \times \frac{4}{3} = \frac{7}{3}</math></p> <p>4. <math>2\frac{1}{3} \div 4\frac{1}{2} = \frac{7}{3} \times \frac{2}{9} = \frac{14}{27}</math></p> |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**DIVISION of Decimals**, is performed the same as in the simple rule of division, observing only to point off in the quotient as many decimal places, as those in the dividend exceed those in the divisor; and if there be not so many, the defect must be supplied by prefixing ciphers. Another way to know the place for the decimal point is this: the first figure of the quotient must be made to occupy the same place either in integers or decimals, as does that figure of the dividend that stands over the unit's place of the first product. *Note*. The division may be carried on to any extent required by annexing ciphers to the remainders after all the given figures have been used.

*Example.* 486·4)748·6840(1·615 quotient.

$$\begin{array}{r} 298 \text{ } 28 \\ 7 \text{ } 444 \\ 2 \text{ } 5800 \\ 1480 \end{array}$$

**DIVISION of Circulating Decimals**, is performed by converting the repetends into their equivalent fractions, and then proceeding as in division of fractions.
